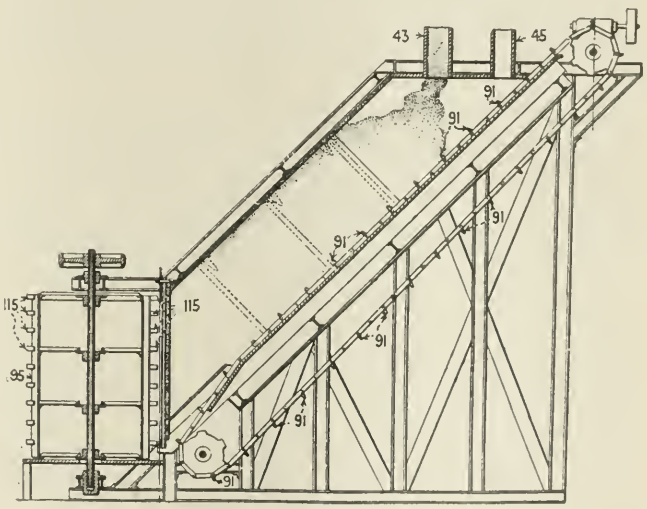
In order to introduce the proper amount of moisture for most efficient conversion, which is held to be 1 grain of water per cubic foot, the gas is passed through a humidifying tower over which is circulated 85 to 90 per cent sulphuric acid at 80 to 100 deg. C. By this means the humidity of the gas entering the converters is maintained constantly at the optimum for conversion. (1,405,669; M. F. Chase, Ardsley-on-Hudson, N. Y., and Frederick E. Pierce, New York, assignors to the COS Process Co. of New York City. Feb. 7, 1922.)

Aluminum Chloride.—The patent covers a process for the production of aluminum chloride from bauxite or other suitable alumina containing material by treatment with a mixture of chlorine and sulphur vapor. The reaction is said to proceed according to the equation:

$$2Al_2O_3 + 3S + 6Cl_2 = 4AlCl_3 + 3SO_2$$

The reaction is to be carried out either in a heated retort into which the sulphur is introduced as a liquid, or in a molten bath of bauxite dissolved in cryolite, through which the chlorine and sulphur gases are passed. The aluminum chloride is in any case evolved as a vapor and is collected or sublimed in any suitable manner. (1,405,115; Frank W. Hall, Port Arthur, Tex., assignor to the Texas Company of New York. Jan. 31, 1922.)

Apparatus for Superphosphate Manufacture.—Thomas J. Sturtevant of Wellesley, Mass., assignor to Sturtevant Mill Co., of Boston, has patented a continuous apparatus for the manufacture of acid phosphate in which the mixture of acid and rock is completely inclosed during the chemical reaction and in which the disintegration of the materials as well as the removal of the noxious fumes are accomplished automatically. A longitudinal section through the machine is shown in Fig. 1. It will be noted the den or chamber is inclined with respect to the floor and discharges directly into the disintegrator. In operation the mixture of ground phosphate rock and acid is introduced through the pipe 43 into the upper end of the chamber. The mixture is still in a



molten or semi-liquid condition and it is therefore necessary to close the door which slides across the lower end of the den. After the mixture has built up back of this door and has stood for a time, it changes from a molten to a solid or spongy form. This effectively plugs the end of the den and the door can then be removed.

The pitch or angle of the floor of the chamber is such that it will be barely sufficient to prevent the mass from sliding along the inclined floor. As a consequence, a slight amount of power transmitted through the sprocket chain and lugs 91 is required. In the disintegrator 95 the knives 115 act on the mass and completely disintegrate it. At the same time, by the fan-like action, the mass is aërated and the moisture permitted to escape in the form of steam. This steam as well as the noxious gases evolved by the chemical reaction are drawn off by an exhauster from the den through the pipe 45.

The process is of course continuous and is timed so that the chemical reaction may be completed and the materials changed from molten to solid form before reaching the disintegrator. (1,403,820; Jan. 17, 1922.)

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Vindication of Dye Industry Seems Imminent as King Charges Prove Blind Leads

As the dye investigation stretches into its fourth week it is becoming increasingly evident that the domestic dye industry will be given a clean bill of health. Chief interest now is centered in whether or not the committee will insist upon information as to the real source of the charges made.

Irenee du Pont expressed the belief, while testifying under oath before the Senate committee, that these charges had their origin in the German Cartel. To illustrate his point he cited a happening in the nursery of his home. Mrs. du Pont came into the room to find that the canary's cage had been thrown over and the bird badly mangled. She did not suspect the children. Her only thought was that the cat was responsible. Mr. du Pont suggested that the committee in this investigation examine the mouth of the cat and see if there are not some yellow feathers sticking to it. He emphasized the fact that the German Cartel must have an agent in this country, but he has not appeared before the committee and no one knows where he is. "I do not accuse Senator King," said Mr. du Pont, "because I think he believes honestly that the charges he makes are true." He emphasized, however, the necessity of ascertaining the source of Senator King's information. He asked why there should be any mystery about the quotations presented from out of the way newspapers. He told the committee that they should find out who furnished the material for those articles and who sent them to Senator King.

The consensus in Washington is that the domestic dye manufacturers have made a very convincing presentation of their side of the case. Despite the limited time to refute charges made by Senator King, there is indisputable evidence that the case against them is superficial to a degree that reflects very unfavorably upon Senator King and the unnamed persons who are holding up his hands.

Herty Answers King's Charges

Monday, March 13, was occupied by the testimony of Charles H. Herty, president of the Synthetic Organic Chemical Manufacturers' Association of the United States. Dr. Herty gave the committee a detailed account of his activities to obtain protection and development for the American organic chemical industry, which he declared is a matter of national necessity. Replying to the assertion by Senator King that the American Chemical Society, of which Dr. Herty was formerly president, was drawn into the campaign for protection for the industry by the Textile Alliance and the American Dyes Institute, Dr. Herty explained that the charge was ambiguous. The latter organization did not exist and the former was not interested in the distribution of dyestuffs when the American Chemical Society began its work for the development of the American industry.

Dr. Herty announced that he has never been a member of the American Dyes Institute and has no connection with the Chemical Foundation, although he is thoroughly sympathetic with its work. Moreover, King's charges that he is a member of the dye advisory committee of the Treasury Department is ridiculous in view of the fact that no such committee exists. The witness told in much detail of his trip to Paris in 1919 before the peace treaty was signed in order to obtain for American consumers necessary German dyes. He represented the State Department and his expenses were paid by the Chemical Foundation.

Dr. Herty added his corroboration to previous statements that there is no combination of any kind and no monopoly in the American industry. He expressed the belief that the embargo offered the only adequate means of protection and that the fear that a monopoly would be created by the embargo could be removed by giving the President power to remove it if any product should become controlled by a monopoly or if American industry failed to manufacture at least 60 per cent of the products needed in the United States. Given proper protection, he concluded, the American manufacturer can produce quantity enough for the American consumer and the American quality is and will be at least equal to that of competitive products.

Dye Business No Bed of Roses for du Ponts

Irenee du Pont, president of E. I. du Pont de Nemours & Co., declared that he sometimes thinks he is "a damned fool" to remain in the dye business in the United States, for the business as he has found it is without profits and the target of constant attack. His company has lost money in dyes during the last 3 years, but he was impelled to hold on because of the great benefits it would accrue to posterity should the American industry have the chance of proper development.

Taking up the ramifications of the business interests of the du Pont company, Mr. du Pont asserted that the size of a company does not make it a monopoly. The parent du Pont Co. is large, but does not have a monopoly on any of the products in which it is interested, he stated.

"There has never been anything nefarious about our operations," said Mr. du Pont. "There has been no agreement, written or unwritten, no gentlemen's agreement or agreement of any other kind to establish a monopoly or to restrain trade. There is no such animal. The only monopoly I know of in the dye industry is the German I. G., the German dye monopoly."

Shortridge Favorably Impressed by Manufacturers' Pleas

During an informal discussion following Mr. du Pont's, testimony Senator Shortridge declared himself in favor of adequate permanent protection of the American dye and organic chemical industry, "by an embargo, if necessary." "I think I may say that from the evidence so far gathered, the present or temporary embargo seems to have worked very well," he added.

It might well be, Senator Shortrige said, that the American dye industry, "a unique industry," needs special, even unusual protection. Some fear that under protection some sort of a monopoly will grow up. But I have no fears on that point. We can take care of our own monopolies by our laws; we would be able to rend them. But our laws do not apply to the foreign monopolies; we have no extraterritorial powers in that respect.

No Monopoly in Dyes Here

The National Aniline Co. is not a monopoly, has no connection with any monopoly in the American dye industry and has no agreement of any kind with any person or corporation for regulation of production or prices or division of prices or territory. This was the substance of the testimony of J. W. Newlean, president of the National Aniline & Chemical Co. "In fact," he went on, "there is nothing in the American dye and organic chemical industry even remotely approaching a monopoly."

"It seems to me that the maximum possible cost to the nation of surely keeping this industry, through a continuation of the selective embargo, is negligible compared with the risk of incalculable loss to the nation necessarily involved in any less certain measure of protection," declared Mr. Newlean. He added that there has been free competi-

tion, unrestricted in any way, under the selective embargo, with the result that the prices of American dyestuffs have steadily declined and are today lower than ever before.

Senator Shortridge announced at the close of Friday's session that John Nash McCullaugh, industrial manager for the National Association of Hosiery and Underwear Manufacturers, had disavowed authorship of or responsibility for the letter purporting to be signed for him and attacking the conduct of the hearing, which was left with the sub-committee recently by George Deming, who represented himself as counsel for the organization. Mr. McCullaugh asked that the letter be withdrawn from the records.

Tariff Commission Statistics

C. R. De Long, chief of the chemical division of the U. S. Tariff Commission, presented figures as to importations of dyestuffs in 1920. These showed that the total imports in that year, about 3,402,000 lb., constituted between 4 and 5 per cent of the total 1920 domestic production, which was approximately 88,000,000 lb.

Total domestic production of all coal-tar products in 1920 was 113,000,000 lb., and of this 88,000,000 lb. was dyes. Mr. De Long said that the total domestic production of all coal-tar products, including dyes, in 1921, estimated on the basis of incomplete reports, was from 40,000,000 to 50,000,000 lb. below the 113,000,000 lb. total of 1920. This decrease is due partly to overproduction in 1920 and partly to loss of export trade because of German competition.

Prompt Action in Granting Import Licenses

F. S. Dickson, chief of the dye and chemical section of the Treasury Department, declared that 90 per cent of the requests for import licenses received by his department are granted within 8 hours after they are received. The others are delayed in order to investigate the applicant's assertion that the American product will not meet his needs in point of price, quality or terms of delivery. About 5 per cent of the applications are refused.

The witness quoted specific examples where the consumers of dyes had requested licenses to import German dyes that are made in this country and the quality of which are such that the consumer actually did not know the difference. Asked his opinion as to existence of a monopoly, Mr. Dickson replied that he had seen no evidence of such thing.

Enamel Brick and Zirconium Refractories Discussed by Chicago Section, American Ceramic Society

Members of the Chicago Section, American Ceramic Society, met at the Hotel Morrison, Chicago, Tuesday evening, March 14. Ross C. Purdy, general secretary of the parent society, spoke informally of work being done by local sections and suggested the possibility of holding joint meetings with the Illinois Clay Manufacturers' Association.

D. F. Albery, of the Northwestern Terra Cotta Co., discussed the manufacture of wire-cut single-fire enamel brick. The brick are formed on an auger machine with a steam-lubricated die, wire-cut on an American down-cut board-delivery cutting table and dried on pallets holding twelve brick each. The dried brick are sprayed with enamel and burnt in the same car-type muffle tunnel kiln which is used for terra cotta.

H. T. Bellamy, of the Western Electric Co., told of his experience with zirconium silicate brick in the crown of a small surface combustion glass tank. No spalling occurred with these brick and there seemed to be practically no deterioration from the fumes. In fact, it was possible to tear down the crown brick by brick and build it up again. In discussing this paper, W. V. Knowles, of Buckman & Pritchard, was called upon to describe the unique deposits of zircon and related minerals found on the Florida coast.

Congressmen to Inspect Muscle Shoals

The Senate Committee on Agriculture, which is considering the offers for the lease of Muscle Shoals, will leave Washington March 25 for a 5-day inspection of the plants. About twenty Senators will comprise the party. The House Committee on Military Affairs, which is likewise considering the offers, will also inspect the plants, the House having passed a resolution authorizing the visit.

Metric System Hearings Close With Rebuttal of Opposition Testimony

Hearings on the Britton-Ladd metric system bill have been definitely closed with the final appearance of representatives of the American Metric Association to rebut the testimony given in opposition to the legislation.

Senator McNary, in the final hearing, asked Howard Richards, secretary of the American Metric Association, if he expected the bill to be reported out in its present form. To this Mr. Richards replied:

"I certainly believe it should be in view of all the evidence that has been brought out. We are ready to consider any modifications, but unless there is some far more important objection than has been suggested so far, we are sincerely of the opinion that the bill is a good bill." Mr. Richards submitted a brief in which he attempted to show that the estimates of the cost to various manufacturers of the compulsory adoption of the metric system which were presented in the testimony of the opposition were unfair.

Theodore H. Miller of the De Laval Separator Co. testified that his company's stand in favor of the metric system was not due to the fact that certain parts used in its machines are made abroad, as intimated in the discussion before the National Council of the Chamber of Commerce. He stated that all parts have been manufactured in this country for machines built in the last 20 years.

Referring to the compulsory adoption of the metric system, Mr. Miller said:

"It is contended that the metric system can be used alongside any other system and that it should not be compulsory. It is fair to compare the system of measurement with the monetary system. The decimal monetary system was of necessity made the only legal standard of values. It was necessary because it had to be used nation-wide or not at all. If it had been optional we still would be using pounds, shillings and pence. Any system which must of necessity be nation-wide in its use must be declared to be the only standard."

Heavy Cut Prescribed by Appropriations Committee Would Reduce Chemical Warfare to Skeleton

The appropriation for the Chemical Warfare Service for the next fiscal year was cut from $1,500,000, the amount carried in the budget, to $500,000 by the Appropriations Committee of the House of Representatives. This drastic reduction means that only a skeleton organization can be maintained and the appropriation bill specifically states that the great manufacturing plants at Edgewood Arsenal are to be held in stand-by condition. With this small appropriation, the work of the Service practically will be limited to research and experimentation. It will mean that the trained personnel which has been gathered together in such a painstaking way must be disbanded for the most part.

Representative Anthony of Kansas, who is in charge of the War Department appropriation bill, explains that this action was taken because of the agreement reached at the Arms Conference. There is a remote possibility that the Senate will increase the item, possibly on the ground that it is the duty of the nation to its soldiers to have on hand at all times a sufficient supply of gas masks to insure their protection in case a possible enemy resort to the use of gas.

The attitude of Secretary of War Weeks was given during his appearance before the Appropriations Committee.

"Personally, I wish that chemical warfare might be banished from the earth forever," he said. "I do not think it will be banished until every nation agrees to its banishment and does so in good faith. I think we ought to carry out the provisions of the treaty in good faith, but just to what extent we should carry on experimentations in connection with this matter is a subject which I think should be fairly and thoroughly discussed.

"Take, as an example, the barrage. There is nothing said about eliminating the barrage. You might develop a much more effective smoke screen than existed in the last war. Just what we should do with the Chemical Warfare Service, outside of manufacturing, which I would not do at all, is a debatable question."

Trade Associations and Department of Commerce to Confer on Dissemination of Statistics

The Secretary of Commerce will hold a conference in Washington with representatives of trade associations the activities of which are national or interstate in their scope on April 12, 1922. It is the purpose of the meeting to get a list of trade associations that will furnish voluntarily to the Department of Commerce the classes of statistical information outlined in the correspondence between the Department of Commerce and the Department of Justice, published on Feb. 16, 1922. Means and methods will be discussed best adapted for collecting and forwarding to the Secretary of Commerce, for dissemination, the classes of statistical information outlined in the correspondence referred to, including the forms of reports that will be most suitable, for associations that are willing to furnish such statistical information.

Meeting of New Jersey Chemical Society

A large and appreciative audience heard two entertaining talks at the meeting of the New Jersey Chemical Society on March 13, in Newark, N. J. C. E. Davis, director of the research laboratory of the National Biscuit Co., gave an outline of the work being done by his laboratory in adapting chemistry and scientific methods to the biscuit industry. Besides the analysis of a large amount of raw material and miscellaneous supplies, the laboratory has worked out methods for the measuring of shortening and has studied the fundamentals of this action and found that increased shortness is merely increased lubrication in the dough, there being no evidence of chemical action. Leavening is also being studied and Dr. Bacon discussed the different forms of bread and biscuits and the different leavens used in them. In this connection he discussed the modern quick leavens, particularly monocalcium phosphate. He also described the modern processes for the preparation of edible gelatine, large quantities of which are used in the biscuit industry. He stated that recent research work has standardized the manufacture to such an extent that any desired properties can be obtained by the scientific maker.

Ellwood Hendrick, Consulting Editor of CHEMICAL & METALLURGICAL ENGINEERING, spoke on the subject, "Out of Chemistry—and In Again." Dr. Hendrick told in a highly entertaining manner of his experience as a student in Germany and amusing incidents in his business career.

Meeting of Executive Board of Federated American Engineering Societies

Steady advancement of engineering ideals both here and abroad and a growing sense of the need and importance of professional unity were outstanding features of the meeting in Chicago, on March 10, of the executive board of the American Engineering Council of the Federated American Engineering Societies. The report of President Mortimer E. Cooley, and of the executive secretary, L. W. Wallace, presented highly encouraging evidence of the favor with which the idea of engineering federation is being received in this and other countries.

A wide range of topics was considered by the board, whose sessions, largely attended, were presided over by President Cooley and the first vice-president, Calvert Townley of New York.

The executive board received a long report from Rudolph P. Miller of New York, its representative on the National Board of Jurisdictional Awards, stating that the United Brotherhood of Carpenters and Joiners of America have not been observing the decisions of the Jurisdictional Board and that the attitude of the carpenters was causing serious embarrassment to owners, architects, engineers, contractors and workmen in the building industry as well as being detrimental to the public interest. As a consequence of this report, the executive board adopted a resolution urging "that the members of the American Institute of Architects and of the F.A.E.S. insert in all specifications and contracts for building operations a stipulation that the decisions of the Jurisdictional Board shall be observed."

One of the liveliest discussions of the meeting of the executive board arose from a resolution presented by Philip N. Moore of St. Louis "that the president of the F.A.E.S. be authorized to offer the Secretary of War the service of a committee of disinterested, distinguished and skillful engineers, to be selected by a committee of its executive board, for the purpose of making a thorough investigation of the geological, engineering and manufacturing possibilities of the Muscle Shoals power project; this committee to serve without compensation, save for necessary expense." The resolution was voted down.

Attention was called to the passage of the Lampert Patent Office bill and to the fact that much credit for the successful outcome of this legislation was due to the patent committee under the chairmanship of E. J. Prindle.

The Sterling bill for reclassification of federal employees was indorsed rather than the Lehlbach bill, since the salary schedules in the former are approximately 10 per cent higher than in the latter and conform more nearly with the report of the original reclassification committee.

Discussion of the proposed international federation of engineers to promote world peace centered on the details of effecting organization in the Americas. A committee was appointed to consider the whole situation as well as possible constitutional changes which would be necessary should the Canadian Institute of Engineers make application for membership.

Refractories Manufacturers' Association Holds Annual Meeting in Chicago

Departing somewhat from the custom of confining convention programs strictly to committee reports and other business matters, the Refractories Manufacturers' Association included a paper by W. A. Hull in the morning session, March 14, of its convention at the Drake Hotel, Chicago. Mr. Hull, who is chief of the refractories section, Bureau of Standards, spoke on the purchase of refractories with particular reference to government activities along these lines. It was found that the government system of purchasing left much to be desired. Through the energetic efforts of Mr. Hoover (who, he said, had taken the "secret" out of secretary) the Federal Specification Board had been formed. Conferences were held between producers and consumers—in the case of refractories the first conference discussed methods of testing, but the second was able to draw up a set of requirements for refractories for coal-fired boilers.

In his presidential address, J. D. Ramsay made a plea for a comprehensive industrial survey of the major operations in which refractory products are used. He suggested a committee of thirteen with a general chairman to consider service conditions in:

1. Blast furnaces, hot blast stoves.
2. Open-hearth furnaces, soaking pits.
3. Heating, puddling and forging furnaces.
4. All types of boilers.
5. Cement, lime and plaster kilns.
6. Window, plate, bottle and optical glass.
7. Annealing, malleableizing and air furnaces.
8. Water- and coal-gas generators, gas producers.
9. Cupolas and gray iron furnaces.
10. Oil refineries.
11. Zinc, lead and copper smelters.
12. All types of byproduct coke ovens.
13. All types of ceramic kilns.

Relations with the Mellon Institute of Industrial Research were brought out in the secretary's report and that of the committee on the Mellon Institute. Support of the fellowship has never been a serious drain on the association's resources because of an arrangement whereby research done for individual companies is paid for by the companies (at rates below those of independent laboratories, however). Thus in 5 years, over $46,000 has been paid for individual research while the association as a whole has had to contribute only about $7,000. In spite of business conditions during 1921, individual research for that year amounted to more than $16,000, as compared with about $13,000 in 1920.

Officers elected were: President, A. P. Taylor; vice-president, F. R. Valentine; treasurer, C. C. Edmonds.

Potash Producers Want Protection

A petition signed by forty-five American potash producers presenting their grievances has been received by Congress. The petition points out the serious effect of German competition on the American potash industry and appeals for relief in the form of moderate protection. Attention is called to the large investments that were made in potash developments during the war and which are now yielding no return because of the surplus of potash that is dumped on the market. It is claimed that German agents are conducting an extensive propaganda in this country to mislead Congress and the public about the needs of the American industry to the end that it may be denied the protection it seeks from foreign aggression.

Conservation of Supply and Continued Experiment Should Reduce Production Cost of Helium

Representative Anthony of Kansas, in discussing the army bill in the House, said that while it provides $400,000 for helium investigations by the army and that a similar fund would probably be authorized for the navy, the Committee on Appropriations was not convinced that with existing facilities helium can be produced commercially.

The cost of government experiments in helium production for the army air service has amounted to $8,016,000, according to testimony given before the Appropriations Committee by officers in charge of this work. When the work first started it cost $1,700 to produce a thousand cubic feet of helium, and this has been reduced to $83.71. The army has 2,400,000 cu.ft. of helium on hand. The government policy in regard to helium was announced to be one for scientific purposes and conservation for war purposes. The army authorities point out that it is desirable to establish continuous production to save the waste in the natural gas districts.

Advances have been made to the army by private interests for the development of helium production on a commercial scale, but no decision has been reached thereon. The army could provide storage facilities for 15 or 18 million cubic feet of helium. Army officers referred to a statement of the Bureau of Mines that the gas fields would probably be exhausted in 20 years. J. W. Davis, mechanical engineer of the Bureau of Mines, testified that with continued development, helium could be produced at a cost of $30 per thousand cubic feet.

Atomic Disintegration of Tungsten Interests Joint Meeting of Mid-West A.C.S. Sections

Members of all sections of the American Chemical Society co-operating in the publication of the *Chemical Bulletin* gathered at Northwestern University at Evanston, Ill., on March 11 for the purpose of participating in a well-balanced intersectional program of social as well as scientific appeal.

At the afternoon session, Harrison E. Howe, editor of the *Journal of Industrial and Engineering Chemistry*, spoke on "Chemistry's Publication Problem." Mr. Howe discussed the editorial and advertising phases of the *Journal*, the News Service, and then outlined some of the plans for enabling the *Journal* to render greater service to the members. Teams representing Milwaukee and Chicago furnished entertainment in the form of an indoor baseball game in the attractive Patten Gymnasium. A score of 11 to 10 in favor of Chicago made up in some measure for the defeat suffered by Chicago at the first intersectional meeting.

After supper the evening program was continued in Harris Hall. Prof. H. B. Lemon of the University of Chicago read a paper outlining preliminary results of some remarkable work by Dr. G. L. Wendt and C. E. Irion on "The Atomic Disintegration of Tungsten." The method employed was suggested by the astronomical researches of Dr. J. J. Anderson of the Mt. Wilson Observatory. If a condenser charged at 100,000 volts is discharged suddenly through a very fine wire, the wire explodes and an instantaneous temperature of between 20,000 and 30,000 deg. C. is obtained. A pure tungsten wire 0.0004 mm. in diameter was exploded in a vacuum tube which gave no spectroscopic lines prior to the explosion. After the destruction of the wire, however, the characteristic lines of helium, hydrogen and mercury were found, indicating atomic disintegration of the tungsten. It was voted unanimously to send a vote of congratulation to Dr. Wendt for this research.

Six group meetings provided ample variety of subject. Dr. H. I. Schlesinger demonstrated the application of absorption spectra methods to the study of the theory of the chamber process for sulphuric acid. Platinum black catalysis was considered by Dr. Roger Adams. Dr. E. J. Forbes spoke on the mineral metabolism of the milch cow; Prof. Edward Bartow on "Relation of High School and College Chemistry." The ladies and non-chemists witnessed a demonstration of the preparation of gelatine desserts and salads by Miss Alice Irwin.

John Arthur Wilson reviewed briefly the circumstances which had led to the development of his much-discussed method for tannin analysis. Attempts to check leather output against tannin input as indicated by the official method of analysis revealed that there was an apparent loss of about 50 per cent of the tannin. Further study showed that certain non-tans such as gallic acid which form hydrolyzable compounds with hide substance were included as tannin by the official method, the error varying with the amount of hide powder used. When the hide powder is washed free of these hydrolyzable substances, the results are constant regardless of the quantity of hide powder taken, and they check with the tannery yields. This forms the basis of Mr. Wilson's method, the washed, tanned hide powder being dried and weighed, giving a result strictly comparable with tannery practice.

Government Co-operating With Engineers in Standardization in Industries

At the request of Secretary of Commerce Hoover, the American Engineering Standards Committee has designated A. A. Stevenson, the retiring chairman of the committee, as a special representative to work with the department in the co-operation between the department's Division of Simplified Practice and the American Engineering Standards Committee. Mr. Stevenson, who is a past president of the American Society for Testing Materials and has had a most extensive experience in standardization work, is vice-president, in charge of manufacture, of the Standard Steel Works Co., which is a subsidiary of the Baldwin Locomotive Works.

The Division of Simplified Practice is a co-ordinating unit of the Department of Commerce assisting in those reductions of excessive variety and other simplifications which many industries are undertaking in order to decrease the cost of production and distribution of manufactured articles. The work of the division was organized in the latter part of 1921 and is now actively under way.

The American Engineering Standards Committee, which serves as a national clearing house for a broad field of engineering and industrial standardization, has offered Secretary Hoover the use of its machinery in carrying out the detailed work on technical projects initiated in the simplification program of the Department of Commerce. The committee has been actively at work somewhat over 2 years, during which time it has brought about a large measure of industry-wide co-operation. In this work more than a hundred national organizations are participating through representatives officially designated by them. The formulation of the standard for each specific project is in the hands of a working committee made up of representatives officially designated by the various bodies concerned. Eighteen standards have received formal approval as nationally recognized standards, and work on more than sixty other projects is in various stages of development. The American Engineering Standards Committee is maintained jointly by twenty-nine national organizations, including five departments of the federal government, nine national engineering societies, and fifteen national industrial associations.

There are now similar national industrial standardizing bodies in thirteen foreign countries, all but one of which were formed during or since the war. Of these the British and the German work is the most extensive, but active and important work is going forward in other countries.

Fish Commission Warns Against Drastic Pollution Prevention Measures

Congress has received a petition from the New Jersey Legislature urging passage of the Appleby bill to protect coastal waters from pollution by fuel oil and waste from chemical and industrial plants.

Warning was given Congress by the U. S. Fish Commission not to injure industry by proposed legislation to prohibit the discharge of oil and other acid wastes into navigable streams in an attempt to save fish from the effect of polluted waters. Officials of the fishery bureau point out that the pending bills before Congress against pollution would practically wipe out some industries on the theory that all pollution was injurious to fisheries, while as a matter of fact it was not known that they are so injurious. They admit that oil pollution is injurious to the fish but say that an attempt to protect fish by drastic legislation without fundamental information might work serious effects on the general business of the country. For example, it is known that the coal mines of western Pennsylvania cause pollution of the Ohio River to the injury of the fish, but obviously this is not sufficient ground for closing those mines. Authority to employ chemists to make a complete study of the effect of pollution on fish was requested.

Personal

R. I. BASHFORD, assistant general superintendent of the Grasselli Powder Co., who has been in charge of its high explosives plants for the past 2 years, has tendered his resignation to become effective April 1.

Dr. ERNEST B. BENGER, director of the Redpath Laboratory of E. I. du Pont de Nemours & Co., is making a brief trip to England in connection with the work of the laboratory on motion picture film.

A. NELSON CHASE, superintendent of the Forcite Works of the Atlas Powder Co., at Landing, N. J., has been transferred to the Darco Corporation's decolorizing carbon plant at Marshall, Tex., as superintendent. This plant is in process of construction and it is expected will be ready for operation about May 1.

Dr. EMIL COLLET of Christiania, Norway, is making a tour of the United States in the interest of Norwegian chemical companies.

R. D. COOKE, chief chemist at the plant of the Columbian Enameling & Stamping Co., Terre Haute, Ind., gave an interesting address before the members of the Indiana Section of the American Chemical Society at the Chamber of Commerce Building, Indianapolis, on March 10, on "Sheet Steel Enamels and Enameling."

JOHN A. ELLIOTT of Pittsburgh has been elected president of the Brinkley Producing & Refining Co. Headquarters of the company are being moved from New York City to Pittsburgh.

W. B. EMMERT, formerly president of the United Central Oil Co., now consolidated with the White Oil Corporation, 66 Broad St., New York, has been elected president of the latter company. He will succeed P. J. White, who becomes chairman of the board of directors.

JOHN R. FREEMAN, JR., returned recently to the Bureau of Standards from a 7 months' trip to Europe, where he visited, for the Bureau of Standards, the principal metallurgical laboratories of France, Germany and England. While in England he worked for about 2 months in the metallurgical department of the National Physical Laboratories under Dr. Walter Rosenhain.

W. A. GIBSON has been transferred from superintendent of foundry for the Owens Bottle Co. to master mechanic for the Libbey Owens Sheet Glass Co., at Charleston, W. Va.

WILLIAM R. HARRIS has been re-elected president of the Monroe Paper Products Co., Monroe, Mich.

H. T. HERRICK, formerly of the National Aniline & Chemical Co. at Buffalo, N. Y., and more recently with the American Aniline Products Co. at Lock Haven, Pa., is now operating chemist of the By-Products Steel Corporation at Weirton, W. Va.

A. C. LANSING has left his fellowship at the School of Mines at Golden, Col., to become chemist with the Lightfoot Schultz Co., soap manufacturer, of Hoboken, N. J.

Dr. W. LEE LEWIS of Northwestern University addressed a joint luncheon meeting of the Chicago Chemists Club and the City Club, Tuesday, March 7, on the subject "Is the Elimination of Gas Warfare Feasible?"

T. A. MITCHELL, chemical engineer, has just returned to the United States after spending 5 years abroad, where he was director of the French branch of the Norsk Aluminum Co. He is now at 30 Church St., New York City, associated with Rogers, Brown & Co.

ROSS C. PURDY, secretary of the American Ceramic Society, addressed the annual convention of Illinois Clay Manufacturers' Association at the LaSalle Hotel, Chicago, March 14, on "The Relation of State Associations to Local Sections of the American Ceramic Society."

CHARLES RUSS RICHARDS, dean of engineering and director of the experimental engineering department of the University of Illinois, has been elected president of Lehigh University. He succeeds Dr. Henry S. Drinker, now president emeritus at Lehigh. Mr. Richards is a graduate of Purdue University and a post-graduate of Cornell.

L. B. RIDDLE has been appointed manager of production for the Shaffer Oil & Refining Co., Chicago, Ill. He recently resigned as assistant manager of production for the Pure Oil Co. of the same city.

Dr. HUGO SCHLATTER, formerly chief of the chemical products division of the Hercules Powder Co., has recently returned from an extended visit to Europe and has opened an office as consulting engineer in the Stephen Girard Building, Philadelphia, Pa. He will specialize in the chemistry of cellulose and its products.

Dr. EDWIN E. SLOSSON spoke on "The Popularization of Science" at a luncheon forum of the City Club, Chicago, on March 14.

Prof. M. DEKAY THOMPSON of the Massachusetts Institute of Technology, Cambridge, Mass., addressed the Franklin Institute, March 5, on the subject "Recent Progress in Applied Electrochemistry."

Obituary

WILLIAM L. PRIZER, manager of the Vacuum Oil Co., New York City, died on March 6, at his residence in New York, at the age of 68 years.

CHARLES C. SPRINGER, managing director of the Mt. Tom Sulphite Pulp Co., Boston, Mass., and for many years identified with the pulp and paper industry, died at his apartments in the Hotel Vendome, on March 9.

Dr. CHARLES W. WAIDNER, chief physicist of the Bureau of Standards, died at his home in Washington, D. C., on March 10 after a protracted illness. He was born in Baltimore, March 6, 1873, and received his early education in the public and private schools there, after which he was graduated from Johns Hopkins University and later received the degree Ph.D. from that institution. He taught for several years, and in 1901 entered the Bureau of Standards, and was connected with that institution as organizer and chief of the work on heat measurements and thermometry practically since the establishment of the bureau. His work was mainly in the fields of temperature and heat measurements and apparatus for the study of thermal phenomena. During recent years his particular problem had been direction of the work on the determination of physical constants used in engineering, especially fireproofing of structural materials and refrigerating engineering. The work on automotive engines also was under his charge.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Wage Comparisons in the Chemical and Allied Industries

Manufacturers in every line of industry are impressed by the urgent need for lower costs of production. Naturally the problems of labor are among the first to absorb their attention, for in this direction lies the obvious, even though perhaps the most difficult, path to lower costs. Wages in most branches of business have already been reduced and in certain industries there is abundant evidence that further reductions are necessary if the manufacturer is to meet the competition which is developing with business revival. It is perhaps worth while, therefore, to give some consideration to the trend of employment and to wage levels both in this country and abroad.

Chemical and metallurgical manufacturers, unfortunately, can obtain relatively little published information regarding wage conditions outside of their own plants. To be sure, some compilations are made at infrequent intervals by the federal government and by labor departments in some of the states, but for the most part these data are not published soon enough to be of value or are too fragmentary to offer adequate basis for comparison. The monthly reports of the Industrial Commissioner of New York may, however, be regarded as an exception, for comprehensive statistics of employment and wages in New York State are now published fairly promptly.

In Table I are given some of the more recent figures for the number of employees and weekly wages in representative New York factories engaged in the production of chemicals and related products. It will be noted that the group "chemicals, oils and paints" exhibits the same general trend as the total for all industries, but has a noticeably higher wage level. However, maximum wages paid in December, 1920, averaged $28.04 for this group, as compared with $28.35 for all industries. The metals group appears to have received the highest wages most consistently, averaging $31.80 for December, 1920, while one subdivision, pig-iron and rolling mill products, reached as high as $36.65 per

TABLE I—EMPLOYEES AND AVERAGE WEEKLY EARNINGS IN REPRESENTATIVE NEW YORK STATE FACTORIES FOR CHEMICALS AND ALLIED PRODUCTS, FOR DECEMBER, 1914 TO 1921

(Compiled under direction of the Industrial Commissioner of New York State)

Chemical and Allied Industries	Number of Representative Establishments and Employees, December, 1921: Total State Establishments	Total State Employees‡	New York City Establishments	New York City Employees‡	Average Weekly Wages in New York State 1921	1920	1917	1915	1914	Average Weekly Wages in New York City 1921	1920	1917	1915	1914

* Reports do not cover a sufficient number of employees to permit the publication of an average weekly earning.

‡ Includes all employees in both office and shop. It is commonly the case that office salaries are higher than the average weekly earnings of shop employees. However, the office employees form such a small percentage of the total number of workers that their effect, in the computation of the average earnings, is negligible.

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

This week	157.49
Last week	157.13
March, 1921	157
March, 1920	252
April, 1918 (high)	286
April, 1921 (low)	140

Of the twenty-five commodities included in this index number, the prices of five have advanced during the past week, two have declined and the others have remained unchanged. The rise in the prices of ammonium sulphate, barium chloride, caustic potash, caustic soda and soda ash more than offset the lower prices for linseed oil and citric acid.

TABLE IA—WAGES AND NUMBER OF EMPLOYEES IN THE DYE AND COAL-TAR CHEMICAL INDUSTRIES IN 1920

(From U. S. Tariff Commission Census of Dyes, etc.)

Wages per Week	Number of Employees at Each Specified Wage Engaged in Manufacturing Operations: Chemists and Technically Trained Men	Men Without Technical Training	All Employees	Percentage Receiving Each Specified Wage Of All Chemists and Technically Trained Men	Of All Men Without Technical Training
Under $10	3	30	33	0.12	0 15
$10, but under $15	15	303	318	0.59	1.54
$15, but under $20	55	618	673	2.15	3 15
$20, but under $25	72	2,038	2,110	2.82	10.38
$25, but under $30	118	3,837	3,955	4.63	19.55
$30, but under $35	201	5,564	5,765	7 88	28 34
$35, but under $40	242	3,431	3,673	9.49	17.47
$40, but under $45	431	1,813	2,244	16.90	9 23
$45, but under $50	214	1,049	1,263	8.39	5 34
$50, but under $75	670	907	1,577	26.25	4.62
$75 and over	530	46	576	20.78	0.23
Total	2,551	19,636	22,187	100 00	100 00

week. The leather group paid the lowest average wage in both 1920 and 1921, but the decrease was much less than in the case of any other group. The most striking wage reduction was in the ceramic industries, where the decrease of $5.98 per week in 1921 was equivalent to approximately 20 per cent of the 1920 wage and to 36 per cent of the 1914 figure.

Using the number of employees in June, 1914, as a basis of 100, the ratio in December, 1921, for the group "stone, clay and glass products" was 79; for the metals group, 95; for leather and rubber, 111; for chemicals, 102; and for paper, 93.

The most recent compilation of wages in the dye and coal-tar chemicals industry is contained in the United States Tariff Commission's "Census of Dyes and Coal-Tar Chemicals, 1920." These figures, reproduced in Table IA, are for the year 1920, and have therefore lost much of their value, for since that time there have been drastic reductions both in wages and number of employees.

International Wage Comparisons

The recent report of the Tariff Commission on "Depreciated Exchange and International Trade" contains a very interesting study of wages and living conditions within some of the countries whose exchanges have suffered depreciation. Commodity prices may be varied almost directly with the exchange, but wage rates shift more slowly and thus those countries whose currencies have depreciated most may derive a corresponding competitive advantage because of low wages as compared with the higher international value of their products. In this connection the Commission makes the following statement:

> The comparative wages in the chemical and metallurgical industries are especially significant. The standard wage in the United States appears to be about 50c. to 75c. per hour and from 30c. to 45c. per hour in England. Germany, on the other hand, shows a rate averaging about 10c. per hour at current exchange, about 18c. per hour in terms of the purchasing power over commodities at wholesale, and from 20c. to 25c. per hour in terms of the cost of living. Inasmuch as many chemical products in Germany are competing directly with similar ones produced in England and the United States, the wage rate at 10c. per hour at current exchange becomes an important factor.

It will be observed in Tables II and III that in the case of Germany, the wages paid in depreciated paper money are converted to American currency in three ways—viz., (1) at the current rate of exchange quoted in New York, (2) at a rate based on German and American wholesale price index numbers and therefore on the basis of relative purchasing power and, (3) at a rate based on the cost of living for an ordinary family in the two countries. In effect this is a translation of nominal to real wages.

These calculations are necessary because of two factors of peculiar significance in the German situation. These are low rents and food subsidies. The report points out that "because of governmental control, rents are only 50 to 60 per cent higher than they were in 1914, an item which holds down the cost of living to a great extent. The food subsidies take the form of government purchases, largely of imported commodities, at the world market price

TABLE V—WAGES IN THE GERMAN CHEMICAL INDUSTRY AND THE MINIMUM COST OF LIVING, 489 ESTABLISHMENTS

(Quoted from *Statistische Reichsamt* by Consul Maurice Parmelee in special report to the United States Bureau of Foreign and Domestic Commerce under date of May 22, 1921.)

	Skilled Workers				Unskilled Workers			
	1914		1920		1914		1920	
	Cost of Living*	Wages	Cost of Living*	Wages	Cost of Living*	Wages	Cost of Living*	Wages
Unmarried men	100	232	100	188	100	161	100	175
Married couple	100	174	100	131	100	121	100	122
Married couple with 1 child	100	162	100	113	100	106	100	107
Married couple with 2 children	100	135	100	103	100	94	100	97

* Includes food, fuel, light, and rent only.

and their resale to German consumers at a substantially lower figure."

In addition to the wages from official sources, the Tariff Commission has obtained some rates from American firms having definite knowledge of foreign conditions. From these data, which are reproduced in Table IV, it will be seen that wages in France and Italy at current rates of exchange were from 15c. to 25c. per hour for common labor and correspondingly more for skilled technicians. These rates appear to be about halfway between the rate for similar occupations in Germany and England and less than half the rates in the United States.

A special consular report to the Department of Commerce, under the date of May 22, 1921, gives some interesting information on the relation between the cost of living and wages in the German chemical industries in 1914 and 1921. This compilation, which includes data from 489 establishments, is shown in Table V. In commenting on this table Consul Parmelee says:

> These figures illustrate very pointedly that, while skilled workers in this industry were apparently not so well remunerated in 1920 as in 1914 in proportion to the cost of living, the unskilled workers were better remunerated in 1920 than in 1914 in proportion to the cost of living. In fact, by the year 1920 the unskilled workers had attained almost as high a level of remuneration as the skilled workers.

Imports and Exports of Chemicals in January

Figures covering imports and exports during January contain little of encouragement to the chemical industries. The total value of exports in January was $7,919,896. This compares with $16,833,454, the value of the exports in January of 1921. The imports in January of this year were valued at $7,517,817. This compares with $12,241,424 in January of last year.

The decrease in imports was confined entirely to the free list. Duitable chemicals increased slightly over the value of those brought into the country in January, 1921. Imports of coal-tar products were less in January by nearly one-half. The value of all coal-tar products imported in January was $720,908. There was only a slight falling off in the value of gums imported. The January figure was $7,272,280. There was a very material increase in imports of carbonate of and hydrate of potash. Increases in the imports of cyanide of soda and muriate of ammonia were noted, but the imports of calcium products fell to nearly one-third the volume of the January, 1921, imports.

Exports of benzene in January were 2,178,420 lb., double the exports of January, 1921. Exports of crude distillates of coal tar fell off decidedly. Exports of colors, dyes and stains of coal-tar origin fell to one-third of the volume in which they were exported in January, 1921. Sulphuric was the only acid moving in volume during January, but shipments were much smaller than in January of last year. The slump also affected in about the same proportion the shipment abroad of acetic, nitric, boric and lactic acids. Calcium carbide and chloride of lime moved in only one-half the rate at which shipments were made in January, 1921.

The New York Market

NEW YORK, March 20, 1922.

There has been a decided expansion in the volume of business transacted in the chemical market during the past week due to both foreign and domestic buying. Present low prices for caustic soda have noticeably improved export business in this chemical. Heavy sales were recorded to Italy, Germany, South America and Japan. There are some interests who expressed the opinion that caustic soda will touch 4c. per lb. before the close of the month. Although the market on soda ash of late is somewhat steadier, it is not showing much of a tendency to strengthen in sympathy with caustic soda. Nitrite of soda reached some new high levels on spot due to the very scant offerings. Yellow prussiate of soda was much easier. Quotations during the week recorded a net loss of ¾c. per lb. Prices opened at 18¼c. per lb. and closed the week at 17½c. Producers of carbon tetrachloride quote lower prices on round lots, but are sustaining recent levels on regular small-lot inquiries. Recent importations of glaubers salt have had a depressing effect on the market and prices on foreign material were generally below 1c. per lb. This is a fraction under prewar figures. The bromides were very much firmer and domestic producers have advanced prices considerably on potassium bromide, which is quoted at 23@24c. per lb. Imported material was very scarce and brought up to 16c. per lb. Barium chloride continued its rise. Sulphate of ammonia is exceedingly scarce in the resale market and prices showed a net advance to 3¼c. with the demand active. Tartaric acid has shown an advancing tendency and the market was very firm with offerings of imported material more restricted.

The Commodity Markets

Arsenic.—Continues very promising and the tone of the market is firm. Dealers are placing small-lot business at 7@7½c. per lb. In some directions 7½c. seems to be the prevailing figure, while others are even quoting as high as 8c. per lb.

Carbon Tetrachloride.—Leading manufacturers are offering carlots as low as 9½c. per lb. Small quantities command a premium and prices extend all the way up to 12c., according to seller and quantity.

Caustic Soda.—Prices for export remain firm and the market shows a tendency to advance among second-hand merchants. Quotations in these quarters are held at $3.70 per 100 lb. f.a.s., for March shipment, $3.60 for April and $3.50 for May-June. The export inquiry is very active and some sellers are sold up for April. Producers' contract prices are sustained at $2.50 per 100 lb., basis 60 per cent, f.o.b. works, in carload lots.

Epsom Salts.—Imported salts are offered at $2.60 per 100 lb. for the U.S.P. Some domestic material has been sold down to $2.50 at the works. The technical grade is not finding any ready market and goods are offered down to 1c. per lb.

Fluoride of Soda.—Leading factors in this commodity were not eager to quote below 10c. per lb., and stated that small consuming orders were being booked at 11c. Offerings are rather scarce and the tone of the market appears quite firm.

Glaubers Salt.—Imported material is offered at 95c. per 100 lb. in bags, on spot and 90c. to arrive. Barrels are quoted at 1.10@1.20, depending on quantity. Domestic goods are held at 1¼@1½c. per lb. Buyers are showing some additional interest of late.

Nickel Salts.—Spot material is not plentiful in the single or double grades and the general condition of the market is reported quite steady. Leading factors state that business in both varieties is going through at 11c. per lb.

Nitrite of Soda.—Scarcity in this chemical is very pronounced at present and holders are limiting their offerings. In first hand quarters it was stated that 9c. per lb. could be done on a firm order, while the majority of dealers are demanding 9½c. per lb. for spot goods. Some large holders of imported material have entirely withdrawn from the market, as they are convinced that higher prices will soon prevail.

Prussiate of Soda.—Lower prices are quoted for spot material and while 17⅜c. per lb. was quoted in some directions, it was intimated that 17½c. could be done on firm orders. The demand seems to have been temporarily satisfied so far as urgent requirements are concerned and a keener competition has developed.

Waxes

Beeswax.—Trading in crude beeswax was slow, but prices held up steady in sympathy with other markets. African crude on spot was available at 15c. per lb. Brazilian crude was quoted nominally at 21@24c. per lb., pure white on spot at 35@40c. per lb.

Montan Wax.—The shipment market held at 4¼@4½c. per lb., with spot material quoted at 4¾@5c. The demand was merely routine.

Paraffine Wax.—The general trend of the market showed

only a slight improvement. Leading producers did not attempt to force business, but tried to sustain current quotations. Match wax attracted some attention and with offerings rather light, prices ruled firm at 4¼@4½c. per lb. Fully refined wax of 125-127 deg. melting point sold at 3½c. per lb., with the 130-132 deg. at 4c. per lb.

Carnauba Wax.—Advices from primary markets indicated a firmer market but prices here did not change a great deal, for the demand has fallen off. No. 3 North Country was quoted at 15½@16c. per lb. No. 2 North Country was steady at 25@26c. pr. lb.

The St. Louis Market

St. Louis, March 16, 1922.

The activity in the local market for industrial chemicals continues and the prospects for the future are very promising. Furthermore, the market is much firmer and the demand for spot and future business is increasing steadily in volume. Many of the weak spots caused by the foreign competition are being eliminated, due to the continued rise of sterling exchange. The local market is very optimistic and producers are putting great confidence in the future.

Alkalis

There has been no change in *caustic* for some time and the present conditions would indicate firmness at prevailing price, one producer of *electrolytic caustic* having withdrawn from this market, being sold up for the time being. *Soda ash* continues to move steadily at prevailing market in less than carlots, and carlots can be purchased as low as $1.75 per 100 lb. in bags f.o.b. St. Louis. *Sodium bicarbonate* is being offered freely at $2.50 per 100 lb. in 1- to 5-bbl. lots. A new factor in the *sal soda* market is offering the regular case goods, 36 packages of 2½ lb. each, at $2.25 delivered buyer's door, with barrels at $1.75.

General and Special Chemicals

The heavy *commercial mineral acids* are still very active with no change in price and market firm. The disturbing element which existed some time ago is gradually coming into line with the present prices. *Citric acid* is moving somewhat better, but there is still lacking the real demand usually expected at this time of the year. Prices are firm. *Carbolic acid crystals, U.S.P.*, is one of the commodities which moves through regular channels and the demand remains practically the same from month to month. Owing to the scarcity of *white arsenic* the market is much stronger and spot lots are now being quoted at 6@7½c. f.o.b. producers' works. Domestic manufacturers of *bromides* have this week advanced their price on the *potash salts* 4c. per lb., other *bromides* remaining unchanged. There is quite a bit of activity in the *bromide* market and business of large volume is passing. There has been practically no cessation in the demand for *bismuth salts* and *iodide salts* for the past 12 months, and today the movement is of as large a volume as at any time. Producers report that they are favorably situated to meet the continued increase. *Carbon bisulphide* is in brisk demand. *Carbon tetrachloride* has not been active and prices are on the easy side. The *copperas* situation is not any easier today than it was several weeks ago. Producers are still unable to take care of business other than their regular customers. Quotations remain the same. *Glycerine* has not changed since our last report and is still being offered at 16c. in drums with a good demand. *Sulphur* has stiffened somewhat, as high as $2.10 being quoted in some instances. A steady demand for *zinc sulphate technical* is still evident and is being quoted at $2.95 in carlots f.o.b. St. Louis.

Vegetable Oils and Naval Stores

Castor oil remains firm and in good demand, the price of 13¾c. in drums prevailing. *Linseed oil* is being quoted today at 87c. basis raw oil, a drop of 2c. within the last 2 days. *Turpentine* offered today at 90c. in barrels, 87c. in drums, a drop of 1½c. since our last report.

Paint Materials

Our anticipated advance in price of *French ochre* stimulated buying in the paint trade recently, there being a rush to get under cover before the new price went into effect. Aside from this the paint trade is very slow at a period when it should be booming.

The Iron and Steel Market

Pittsburgh, March 17, 1922.

The chief point about the steel market now is whether demand will continue at its recent rate, not whether it will increase farther. The rate of steel ingot production in the past 3 weeks has ranged between 29,000,000 and 30,000,000 tons a year, while the two best pre-war years, 1912 and 1913, each showed a production of 30,275,000 tons. The decrease in exports is sufficient to cover the difference between these figures, so production for domestic consumption is now running at the average rate in the two best years before the war. As the general industrial or business situation in the country is regarded as unsatisfactory, rather than as measuring up to the highest standard before the war, there cannot be much complaint as to this item of the volume of steel demand, and the real market question is whether it will continue indefinitely, increasing as general and basic conditions improve.

Considering the time of year and the fears of not a few buyers that production and shipment of steel might be curtailed by the expected coal strike April 1, there is reason to suspect that a portion of the recent steel buying has been for stocking purposes.

There is no prospect that the coal strike will handicap the steel mills. It is unlikely, though it is not impossible, that production in the non-union fields, like the Connellsville region, will be interfered with by sympathetic strikes, and the non-union capacity is fairly large relative to the present rate of coal consumption. Consumers of coal are known to have been stocking coal and the weakness in the coal markets in most districts in the past fortnight, with definite declines in prices in some districts, including Pittsburgh, indicates that consumers are not being caught with smaller stocks than they think necessary.

With domestic demand for steel running at approximately the rate of 1912 and 1913 it is interesting to note the differences in distribution. Production of rails and plates is much less, while production of tin plates and sheets is much greater. In tubular goods there is more tonnage in standard pipe and less in oil country goods. In wire mill products there is less in fencing and probably more in nails. In bars and structural shapes there is probably little difference.

Steel Prices

As to prices, the steel market is probably a trifle stiffer, on the whole, than a week or two ago. There has been an effort to get bars, shapes and plates up to 1.50c. as a stabilized figure, and this has succeeded to the extent that quotations under 1.40c. are now relatively uncommon. Shading in tubular goods seems to be a trifle less extensive. Sheets show no change, as they have been rigid right along, at 3c. for black and 4c. for galvanized. Hoops are a shade stronger, with concessions under 1.80c. uncommon and 1.90c. well maintained on cut hoops. Nails, however, show more frequent concessions than formerly from the regular $2.40 price.

Pig Iron

Two sales of basic pig iron at $18 valley furnace re-established the market at that figure, after a spell in which $17.75 was the usual selling price. One of the sales was of 600 tons by a steel interest, the other being 1,000 tons by a merchant furnace interest. Foundry iron has sold so frequently at $19 valley, although in small lots, that this may be considered the market, against a range of $18.75@$19 formerly quoted. Bessemer remains at $19.50 valley in small lots, with a possibility of shading in case of a large tonnage.

Coke

Connellsville coke, which stiffened somewhat at the close of last week, is easier this week, with spot prices the same as quoted one week or two weeks ago, $3.25@$3.50 for furnace and $4.25@$4.75 for foundry. There is no decrease in demand to account for the easier tone, which is obviously due to the distinct decrease in late in demand for coal, a decrease that must be considered in the light of the fact that Connellsville operators expected an increase, or a last minute rush, as April 1 was approached, on account of the prospective suspension at the union mines.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.	..... –	$0 40 – $0 42

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb.	$1.00 —	$1.05
Alpha-naphthol, refined	lb.	1.10 —	1.15
Alpha-naphthylamine	lb.	.30 —	.31
Aniline oil, drums extra	lb.	.16½ —	.17
Aniline salts	lb.	.24 —	.26
Anthracene, 80% in drums (100 lb.)	lb.	.75 —	1.00
Benzaldehyde U.S.P.	lb.	1.25 —	1.30
Benzidine, base	lb.	.85 —	.95
Benzidine sulphate	lb	.75 —	.85
Benzoic acid, U.S.P.	lb.	.60 —	.65
Benzoate of soda, U.S.P.	lb.	.55 —	.57
Benzene, pure, water-white, in drums (100 gal.)	gal.	.29 —	.35
Benzene, 90%, in drums (100 gal.)	gal.	.27 —	.32
Benzyl chloride, 95-97%, refined	lb.	.25 —	.27
Benzyl chloride, tech	lb.	.20 —	.23
Beta-naphthol benzoate	lb.	3.75 —	4.00
Beta-naphthol, sublimed	lb.	.60 —	.65
Beta-naphthol, tech	lb.	.27 —	.30
Beta-naphthyla mine, sublimed	lb.	1.50 —	1.60
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 —	.15
Ortho-cresol, in drums (100 lb.)	lb.	.16 —	.18
Cresylic acid, 97–99%, straw color, in drums	gal.	.50 —	.52
Cresylic acid, 95-97%, dark, in drums	gal.	.45 —	.47
Dichlorbenzene	lb.	.06 —	.09
Diethylaniline	lb.	1.10 —	1.15
Dimethylaniline	lb.	.38 —	.40
Dinitrobenzene	lb.	.22 —	25
Dinitroclorbenzene	lb.	.23 —	25
Dinitronaphthalene	lb.	.32 —	.35
Dinitrophenol	lb.	.35 —	38
Dinitrotoluene	lb.	.22 —	.24
Dip oil, 25% car lots, in drums	gal.	.24 —	26
Dipnenylamine	lb.	.59 —	.70
H-acid	lb.	.85 —	1.00

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—The Birmingham Water Works Co. will install new filtration and purification equipment at its plant in connection with general improvements and extensions. The company is arranging for an increase in capital from $2,529,700 to $3,039,700, and more than one-half of the proceeds will be used for the work.

California

MOJAVE—The Jo Rand Smelting Co., Bakersfield, Cal., recently organized, is planning for the erection of a new smelting plant on site selected at Mojave. R. L. Gilmore, Bakersfield, is secretary and treasurer.

BOALINGA—The Council has called a special election, April 10, to vote bonds for the erection of a 100,000 cu.ft. gas plant and holder for municipal service.

Delaware

WILMINGTON—The Martin Leather Co., 703 East 5th St., has filed plans for the erection of a 2-story addition to its tanning plant, with wings, 47 x 126 ft. and 36 x 48 ft.

Idaho

COEUR D'ALENE — Idaho Clays, Inc., recently organized, is perfecting plans for the erection of a new plant on site selected in the Hayden Lake section in the eastern district of the city. The plant will consist of a number of buildings for the manufacture of a general line of burned clay products, estimated to cost about $500,000, including machinery. The works will include a power plant for operation.

Indiana

VALPARAISO—Frank W. Lesch, superintendent at the plant of the Pitkin & Brooks Glass Co., has acquired the plant and property of the company and will take possession on May 1. It is purposed to discontinue operations at the local factory and remove the machinery to another location, where increased manufacture will be provided. The local Chamber of Commerce is interested in the project.

Kentucky

LEACH—The Great Eastern Refining Co. is planning for the erection of a new oil refinery on local site to cost about $250,000, including equipment. Plans will be drawn at an early date.

Maryland

BALTIMORE—The Patuxent Clay Products Co., 210 Equitable Trust Bldg., has selected a site at Patuxent, Md., for the erection of a new plant for the manufacture of a line of burned clay products. It will consist of a number of buildings, estimated to cost about $100,000, including equipment. I. P. Mills is in charge.

BALTIMORE — The Colloidal Process Paint Co. has work in progress on a new local plant, to be used primarily for the processing of bitumens.

BALTIMORE—The Prudential Oil Co., Keyser Bldg., has acquired a tract of land adjoining its plant on 7th St., East Brooklyn, totaling about 6⅛ acres, to be used for extensions. The property was obtained for a consideration of $22,000.

BALTIMORE—Gilpin, Langdon & Co., Inc., 300 West Lombard St., manufacturer of chemicals, drugs, etc., has broken ground for the erection of a 1-story plant, 65 x 211 ft., at Smallwood and Eagle Sts., estimated to cost about $55,000. Frainie Bros. & Haigley, 19 Clay St., are the building contractors.

BALTIMORE—The Atlas Chemical Laboratories, Inc., 1717 Mosher St., recently organized with a capital of $50,000, has plans under way for the establishment of a local plant for the manufacture of chemical sanitation specialties. It is planned to commence operations at an early date. John E. Auld, Jr., is president, and John E. Auld, Sr., treasurer.

Massachusetts

EVERETT—A portion of the works of the Merrimac Chemical Co., located on the banks of the Mystic River, including three buildings, was destroyed by fire, March 7, with loss estimated at about $20,000.

LEOMINSTER—The Atlantic Refining Co., Hospital Trust Bldg., Providence, R. I., will commerce work at once on a new oil-distributing plant on North Main St., Leominster.

Michigan

DETROIT—The Detroit Sand Lime Brick Co., 507 Vinton Bldg., is completing plans for the erection of its proposed new plant on property recently acquired at River Rouge, Mich., to consist of a number of buildings. It is expected to call for bids at an early date.

BAY CITY—The local Chamber of Commerce has announced that the Andrews Steel Co., Newport, Ky., affiliated with the Kentucky Rolling Mills Co., of the same place, has taken an option on Bay City property, totaling about 150 acres, to be used as a site for the construction of a new blast furnace and steel works.

Missouri

ST. LOUIS—Fire, March 6, destroyed a portion of the plant of the Perfection Enamel Corp., 4528 Page Ave. The fire started in one of the drying ovens. An official estimate of loss has not been announced, but is said to be heavy.

Montana

GREAT FALLS—The American Zinc, Lead & Smelting Co., 120 Broadway, New York, N. Y., has acquired a controlling interest in the Silver Dike Mining Co., operating in the Great Falls district, for a consideration said to be $125,000. The production is silver-lead-copper ores, and the new owner plans for extensive development and production.

New Jersey

TRENTON—The Star Porcelain Co., Muirheid Ave., has awarded a contract to the Karno-Smith Co., Trenton, for the construction of a new 1-story building at its plant, 71 x 101 ft.

NEWARK—The United Color & Pigment Co., Evergreen and McClellan Aves., has filed plans for the erection of an addition to its plant to cost about $22,000. Work will be commenced at once.

BLOOMFIELD—A water-softening and filtration plant will be installed at the new local bleaching plant to be erected by the Clark Thread Co., 260 Ogden St., Newark, estimated to cost about $200,000.

New York

HUDSON—The Hudson City Steel Co., 233 Broadway, New York, N. Y., has plans nearing completion for the erection of its proposed new plant at Hudson, to comprise six 1-story buildings, equipped for general steel products manufacture, estimated to cost close to $900,000, with machinery. The work will be commenced at an early date. Dwight P. Robinson & Co., 125 East 46th St., New York, are engineers.

NEW YORK—The Rose Novelty Mirror Works has leased space in the building at 65-69 Varick St., for a new factory for the manufacture of mirrors and other kindred glass products.

TONAWANDA—The Beaver Board Co. has closed down its local works for extensive improvements and repairs. It is expected to have the plant ready for service in August. In the meantime, the company will concentrate on the manufacture of its composition wallboard products at its works at Thorold, Ont.; it is planned to install new equipment at this plant, and to increase the working force by at least 100 men.

BUFFALO—The Water Bureau, George G. Andrews, Water Commissioner, City Hall, has plans in progress for the construction of a new filtration plant for the local waterworks, to be located at the Col. F. G. Wood Pumping Station. It is estimated to cost in excess of $3,500,000, and the city has appropriated funds greater than this amount to carry out all details of installation. Clark D. Parsons, Fort Porter Ave., is engineer.

North Dakota

WILLISTON—F. J. Wilkinson, vice-president of the Williams County Bank, and associates are organizing a new company to construct and operate a local leather tannery. It will be 2-story and basement, 60 x 125 ft. and estimated to cost approximately $30,000. George E. Ellinger, Havre, Mont., is architect.

Ohio

UTICA—The Licking Window Glass Co. is planning for the rebuilding of the portion of its plant, destroyed by fire, March 5, with loss estimated in excess of $100,000, including equipment. Harry McCann is president.

CINCINNATI — The Ultra-Marine Co., Huntington, W. Va., will soon take bids for the erection of a new 1-, 2- and 3-story plant in the vicinity of Cincinnati, estimated to cost in excess of $60,000. U. S. G. Anderson is president; E. C. Baugher, 539 22nd St., Huntington, is in charge of the project.

LIMA—The Lisbon Agricultural Lime Co., recently organized, has taken over the plant and business of the Lisbon Lime Co., and will operate the works in the future. Plans are under way for enlargements in the plant, with the installation of new equipment in different departments.

Oregon

PORTLAND — The Portland Vegetable Oil Mills Co., care of W. H. Curtis and L. R. Russe, engineers, Portland, will build a new local plant for the production of turpentine, rosin and kindred wood byproducts, to be extracted from Douglas fir pitch. Plans will be drawn at an early date. H. H. Ward is one of the heads of the company.

SCAPPOOSE—The Oregon Charcoal-Iron Co., A. W. Martin, head, has plans under way for the erection of a new plant, with furnace, etc., on local site. It will be used for pig-iron production and work will be placed under way at an early date. The complete plant is estimated to cost about $200,000.

Pennsylvania

BRADFORD—The Interstate Glass Co., Bradford, has commenced work on extensions and improvements at its plant at Clarksburg, W. Va., estimated to cost about $70,000. L. E. Stewart, Bradford, is engineer, H. J. Walters is president.

PITTSBURGH—Fire March 8 destroyed a portion of the plant of S. Struntz & Son, 702-716 Bingham St., manufacturers of soaps and kindred products, with loss estimated at about 40,000.

KANE—The Interstate Window Glass Co., Kane, is dismantling its plant at Smethport, Pa., including blowing machines, etc., and at a later date will install new and improved equipment to replace the machinery. Operations have been discontinued during the change.

Texas

NEW BOSTON—Fire Feb. 28 destroyed a portion of the plant of the New Boston Cotton Oil Co., with loss estimated at about $75,000, including equipment. It is planned to rebuild.

THREE RIVERS — The Three Rivers Glass Co., recently organized, will establish a local plant for the manufacture of glass bottles and other glass products. H. L. Warrick is general manager.

West Virginia

CASS—The West Virginia Pulp & Paper Co., 200 Fifth Ave., New York, is said to be planning for the rebuilding of the portion of its pulp and wood plant at Cass, recently destroyed by fire with loss estimated at about $200,000, including equipment.

Washington

SPOKANE—The Western Materials Co. is planning for the erection of a new magnesite mill on local site, to handle production from its quarry at Springdale, Wash. F. M. Handy is manager in charge.

Capital Increases, etc.

THE WHITE OIL CORP., 66 Broad St., New York, N. Y., has filed notice of increase in capital from $100,000,000 to $201,500,000.

THE O'NEAL LIME WORKS, INC., Wilmington, Del., has been incorporated under state laws with capital of $2,000,000, to manufacture lime and affiliated products. The company is represented by the Corporation Service Co., Wilmington.

THE VERM-O-SPRAY PRODUCTS, INC., West Haven, Conn., has been incorporated with a capital of $50,000, to manufacture insecticides, chemical products, etc. The incorporators are Charles Vincent, A. G. Sargent and Maurice Sulzbach, 78 East Ave., West Haven.

THE DIAMOND CANDLE Co., Brooklyn, N. Y., has been incorporated with a capital of $40,000, to manufacture candles, wax products and affiliated specialties. The incorporators are C. and G. F. Schisano, and H. T. Rosenfeld. The company is represented by Samuel Stark, 280 Broadway, New York.

THE MECHLING BROTHERS CHEMICAL Co., Camden, N. J., has been incorporated with a capital of $1,000,000, to manufacture chemicals and chemical byproducts. The incorporators are William H., Edward A. and Benjamin S. Mechling, Line St. and Cooper's Creek, Camden.

THE C. H. WOLFELT Co., New York, N. Y., has been incorporated with a capital of $400,000, under Delaware laws, to manufacture leather and rubber products. The incorporators are C. Irving Brown, James L. Watson and Tracy S. Buckingham, New York. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del.

THE ROSMIL FIBRE Co., Boston, Mass., has been incorporated with 1,000 shares of stock, no par value, to manufacture fiber products. William R. Rogers is president; and M. F. McGrath, 293 Washington St., Boston, treasurer.

THE SUNSET TILE Co., 947 Elden Ave., Los Angeles, Cal., has filed notice of organization to manufacture ceramic tile products. The company is headed by G. S. Sinclair and C. S. Wallace.

MCCALVIN & Co., Jacksonville, Fla., has been incorporated with a capital of $10,000, to manufacture soaps and kindred products. W. W. Parker is president and treasurer; and S. A. Logan, secretary, both of Jacksonville.

THE AMERICAN B. F. R. MFG. Co., 848 Noble St., Chicago, Ill., has been incorporated with a capital of $15,000, to manufacture leather products. The incorporators are Isaac F. Potter, Peter P. Reisenhus and Baldwin S. Benton.

THE FLUID CHEMICAL Co., 149 High St., Newark, N. J., has filed notice of organization to manufacture washing fluids and other kindred chemical products. The company is headed by Frank Salvato.

THE ENDYNE CHEMICAL Co., Wilkinsburg, Pa., has been incorporated under Delaware laws with capital of $100,000, to manufacture chemicals and chemical byproducts. The incorporators are H. G. Hurney, Pittsburgh, Pa.; George L. and B. B. Ayres, Wilkinsburg. The company is represented by the Capital Trust Co. of Delaware, Dover, Del.

THE LARKUM-WALD Co., Mt. Vernon, N. Y., has been incorporated with a capital of $5,000, to manufacture chemicals and chemical byproducts. The incorporators are E. S. and I. C. Larkum, and M. Wald. The company is represented by H. D. Lent, Mt. Vernon.

THE PADUCAH CLAY Co., Paducah, Ky., has been incorporated with a capital of $25,000, to manufacture clay products of various kinds. The incorporators are James S. Escott, E. I. Milburn and Elmer C. Ries, all of Paducah.

THE R. J. SPROUT LEATHER Co., INC., Boston, Mass., has been incorporated with a capital of $5,000, to manufacture leather products. Robert J. Sprout, Everett, Mass., is president and treasurer.

THE KE-TOY MFG. Co., Brooklyn, N. Y., has been incorporated with a capital of $10,000, to manufacture soaps and kindred products. The incorporators are R. L. Gordon and J. Margolis. The company is represented by Benjamin Marvin, 386 Fulton St., Jamaica, L. I.

THE REITER OIL CORP., Wilmington, Del., has been incorporated under state laws with a capital of $1,000,000, to manufacture petroleum products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE SILVER REDUCTION Co., 2426 Clybourn Ave., Chicago, Ill., has been incorporated with a capital of $50,000, to manufacture chemical solutions, metal reduction products, etc. The incorporators are Charles E. Johnson, Emerson B. Stoddard and Ralph E. Rich.

THE FLORIDA NOLENE PAINT Co., Lemon City, Fla., has been incorporated with a capital of $25,000, to manufacture paints, varnishes, etc. I. B. Padgett is president; and W. D. Many, vice-president, both of Lemon City.

THE PALMER PRESSED BRICK WORKS, INC., Palmer, Ellis County, Tex., has been incorporated with a capital of $21,000, to manufacture bricks and other burned clay products. The incorporators are J. R. Beck, Y. Barron and L. B. Griffith, all of Palmer.

H. P. DANIELSON, INC., 300 West Lake St., Chicago, Ill., has been incorporated with a capital of $25,000, to manufacture leather products. The incorporators are Leo P. Wall, H. P. Danielson and Harold M. Pine.

THE GRUBER VARNISH CORP., New York, N. Y., has been incorporated with a capital of $500,000, to manufacture paints, varnishes, etc. The incorporators are L. H. and F. R. Gruber, and L. Estander. The company is represented by Henry Hoelljes, 95 Madison Ave.

THE CONTINENTAL COLOR & CHEMICAL Co., Boston, Mass., has filed notice of organization to manufacture chemicals, colors, etc. The company is headed by Tracy L. Evans, 34 Merchants Row, Boston.

THE JOHN B. HEDIAN Co., 809 Hillen St., Baltimore, Md., has been incorporated with a capital of $20,000, to manufacture salt products and affiliated specialties. The incorporators are John B. Hedian and Charles B. Hoffman.

THE COOPER Co., Elwood, Ind., has been incorporated with a capital of $50,000, to manufacture steel and other metal castings. The incorporators are Clayton C. Cooper and William T. McNamara, both of Elwood.

THE PENINSULAR PHOSPHATE CORP., Wilmington, Del., has been incorporated under state laws with a capital of $1,500,000, to operate phosphate properties, manufacture fertilizers, etc. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

F. HOUT & Co., New York, have been incorporated with a capital of $5,000, to manufacture soaps and kindred products. The incorporators are R. P. Bramley and A. Henderson. The company is represented by H. A. Richards, 56 Pine St., New York.

Coming Meetings and Events

AMERICAN CHEMICAL SOCIETY will hold its spring meeting at Birmingham, Ala., April 4 to 7, 1922.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Baltimore, April 27, 28 and 29, 1922. Headquarters will be at the Emerson Hotel.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Rochester, N. Y., during the week of June 5, 1922. Meetings will be held in the spring instead of in the fall as heretofore.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its summer meeting at Niagara Falls, June 19 to 22. Headquarters will be at the Clifton Hotel.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its nineteenth annual meeting at Bigwin Inn, Bigwin Island, in the Lake of Bays district, Ontario, Canada, on June 21, 22 and 23.

AMERICAN SOCIETY FOR STEEL TREATING will hold a sectional meeting at the Bureau of Mines auditorium, Pittsburgh, Pa., on May 25 and 26. The International Steel Exposition and Convention of the society will be held in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-fifth annual meeting June 26 to July 1, at Atlantic City, N. J. Headquarters will be at the Chalfonte-Haddon Hall Hotel.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY will hold a meeting at Lyons, France, June 27 to 30.

IRON AND STEEL INSTITUTE (British) will hold its annual meeting on May 4 and 5 at the House of the Institution of Civil Engineers, Great George St., S. W., 1, London.

NATIONAL ASSOCIATION OF PURCHASING AGENTS EXPOSITION (the "Informashow") will be held in connection with the seventh annual convention of the association at Exposition Park, Rochester, N. Y., May 15 to 22.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists Club, New York: March 24—Society of Chemical Industry, regular meeting; April 21—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting; May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting; June 9—American Chemical Society, regular meeting.

Measuring Ideas

"IT IS difficult to measure ideas in terms of specific or ad valorem duties. . . . The dye industry involves more than the mere producing of commodities. . . . This industry is unique and it may require unique forms of protection."

These very significant and highly encouraging statements are almost verbatim remarks by Senator SHORTRIDGE, who has been conducting the hearing regarding activities of the dye industry and of dye importers. The remarks occurred just before the Senator made a preliminary informal report to the Finance Committee of the Senate, which is drafting the tariff bill.

Chemical industry can well take encouragement from these comments. Its case has been forcefully and fairly presented thus far. Criticism of the industry has been vitriolic, but based upon false assumptions and misapprehension. The truth regarding the situation is being most satisfactorily brought out by the proceedings and the truth certainly promises to be helpful to the cause of the industry, as might have been known in advance by anyone who took the pains to find out how meritorious and patriotic has been the effort of those who have labored for the establishment of an organic chemical industry in the United States.

The Price of an American Potash Industry

OUR potash people are petitioning Congress for what they consider a moderate scale of protective duties and we are inclined to think that their demands are not exorbitant. Somehow or other we have been steeped in German propaganda for so long and the idea has become so prevalent that the Creator appointed Germany the custodian of the world's potash that it appears almost irreverent to defend an industry elsewhere than in der Vaterland. That is just what we intend to do, however, for a close study of the facts regarding the American potash industry has convinced us that it is deserving of the sink-or-swim chance which the proposed tariff will afford it. Given this protection for 5 years, it is our firm opinion that the nucleus of a potash industry can be developed that will stand on its own feet and justify its existence in competition with the foreign industry. The crux of the situation lies in the successful development of Searles Lake and the lowering of transportation costs by a water route through the Canal and around to the Atlantic seaboard.

In the first place, just to get it off our chest, we want to admit that the domestic industry has many shortcomings and that many acts of its own have stood in the way of its best development. The producers themselves have been responsible for much of the misinformation about the American potash industry. They have met the propaganda we referred to in our opening sentences with similar propaganda, and we are not prepared to say which has been the worse. Stock-selling schemes, wildcat projects and engineering monstrosities have been too common and have caused many potential friends of the industry to lose faith in its future. Another and in our opinion a most serious handicap has been the lack of unity in the ranks of potash producers. The reason, of course, is that our output has come from a dozen widely different sources, representing so many varying costs of production and so many clashing interests that there could be no single voice to speak for the industry. To be sure, the Potash Producers Association in Washington has met this need to some extent, especially as far as legislative activities are concerned, but it is in the industry's business relations that the lack of unity has been most evident. Negotiations with the grouped buyers of the fertilizer industry and the attempts to meet the organized competition of the German and Alsatian potash syndicates called for unified action, but unfortunately resulted in friction and discord.

The tariff for which the industry is petitioning is the sliding scale of duties contained in the bill which passed the House last summer. Under this arrangement the potash producers claim that they can resume operations and build up their production to a basis on which they can meet foreign competition without further aid from the government. They ask for but a fighting chance to go ahead and, sink or swim, they are willing to abide by the results. Obviously not all the producers can compete, even with the benefit of the duty, but many of the plants can continue in business if they have the assurance that they will receive a fair price for their product. As these plants enlarge operations, they will lower their costs and thus become better prepared to meet the inevitable competition. Expansion in a going concern usually means only a multiplication of present units, with consequent savings not only in construction costs but in distribution of overhead charges.

The brief of the potash producers, which is reviewed in the news pages of this issue, holds a lesson for other of our chemical industries which are suffering from foreign competition and are half-heartedly awaiting the relief promised them by Congress. The devastation in the dye industry, for example, is not so complete as among the potash producers, but it is evident that the same agencies are at work.

But sizing up the problem from the broad national viewpoint, there are certain outstanding facts about the potash situation which we must not forget. The war taught us the value of several key industries, and a surprising proportion of these were our basic chemical industries. Potash proved to be one of those essential commodities the supply of which we suddenly found was lacking from our industrial make-up. Now, by long and

tedious experimenting and costly research, we have developed the makings of a creditable potash industry. If we permit it to thrive in this country, it will mean that in case of another emergency we will have the nucleus around which we can build up an industry to take care of our entire demands. If, on the other hand, we permit the industry to die, we return to the hands of the foreign producers and the price we must pay for our future supply of this essential element will be dictated by the syndicates in Berlin and Paris.

It is scarcely necessary to urge the chemical industries to lend their support to the potash tariff. The price to be paid for this domestic industry is insignificant in comparison with its value to chemistry in America. If our entire chemical independence could but be purchased by the adoption of such moderate rates of duty, we would indeed have cause for rejoicing.

Lowering Costs and Increasing Production Efficiency

THE necessity of lowering production costs is now generally acknowledged if prices are to be such as to encourage sales and meet foreign competition. Unquestionably costs have been lowered by some manufacturers as far as circumstances will permit, with the result that their business is generally in a better condition than the average. But there still are too many plants where the costs have not been reduced as they should be. Many are trying to carry on with the methods established before the war, and made perhaps more inefficient under the pressure of war production. Conditions in such cases are capable of improvement; but those responsible are beset with conflicting advice, and fear that the expenditures necessary to put their plants in condition to compete are beyond their means. Also, sometimes the inertia of old ways is too strong.

What course, then, should be followed by those who must lower costs and are willing to make the attempt? Is there any definite plan that can be used in all cases to attain this end? We think not. But in spite of the general discredit thrown by the panacea peddlers on those who give advice, there is a counsel of common sense which if applied with fair judgment should do much to bring about the desired ends.

The problem should be studied with a view to applying sound principles that have led to efficient results for others, together with such other measures as the special case may require. All preventable waste must be eliminated. Processes must be arranged to flow continuously in the straightest possible line. Sufficient auxiliary equipment must be added to bring the existing machinery of production to its highest efficiency. Steps must be taken to organize so that the inventory of goods in process is at all times at a minimum. Everything possible must be done to heighten the morale of the workers and to keep the labor turnover at the lowest figure obtainable. The burden of management must be lessened by the elimination of all unnecessary employees and the reduction of the product and its process of manufacture to the simplest terms.

These principles form the framework upon which a comprehensive plan of improvement can be hung. Each must study out his own problem. But, taking these principles as a basis of action, if a definite program is formed and put into effect, the result for that plant can scarcely fail to be lower costs and increased production efficiency.

Furniture For Firewood

CONGRESS is making kindling out of our national furniture with a vengeance. This conclusion seems inevitable when we witness the procedure of the House of Representatives Appropriations Committee ruthlessly hacking at the organization of the executive departments. One of the latest evidences to confirm this idea is the cut which was made in the appropriation for the U. S. Geological Survey. In this case, not content with cutting off the increases which even the hard-headed business men of the budget bureau had approved, the committee slashes still further and makes actual decreases below current funds in several important items for the support of geologic and engineering work.

It takes years to build up a smoothly working efficient scientific organization of any sort in a field of complicated endeavor in research or exploration. In this respect the U. S. Geological Survey is no exception. Its high standing and high standards of performance are the result of years of development and training of its personnel. To cut down such an organization below its pitifully inadequate strength of this year is worse than foolish. It is nationally and economically criminal.

We suggest that our national legislators chop wood on an appropriate woodpile and not hack up the national scientific furnishings of the government in this fashion.

Is It "Exportable Surplus"?

THERE has been a general tendency during recent months to assume that the ammonium sulphate produced in the United States which does not find ready market here is exportable surplus. On the basis of this assumption, Mr. MACDOWELL, president of the National Fertilizer Association, recently estimated that 150,000 to 200,000 tons of ammonium sulphate is produced which will not find market in the United States. He, therefore, has characterized this as a "normal exportable surplus."

It is a demonstrated fact that fertilization of even relatively new soils is a paying proposition. Improvement in economic conditions of the country demands such fertilization. Moreover, the farmer is beginning to realize these facts, and one is not unduly optimistic in assuming that the use of fertilizers is going to increase rapidly in the next few years, even to the extent of doubling the demand within 5 or 10 years. Of course the pace at which increase will come will be determined more largely by economic conditions—that is, the ability of the farmer to buy—than by any other factor. However, it seems likely that this increase in demand will outstrip the increase in production of ammonium sulphate from existing agencies, even though the metallurgical industries demand coke production up practically to the capacity of the coke ovens of the country and thereby increase materially the byproduct ammonia output. The increase in use of fertilizers may therefore be more than enough to absorb all of what we now call "exportable surplus."

There will be continuous readjustment of the relationships of nitrogen production and nitrogen utilization during the coming years. Even a resumption of active purchasing by farmers, a normal operation of metallurgical coke plants for byproduct ammonia output, and the settlement of the question of Muscle Shoals, large as that question now looms on our political horizon,

will not decide the whole situation. The readjustment of relationships will be largely affected also by the new technology of nitrogen fixation, now a demonstrated commercial success. Any interest in the nitrogen industries which neglects this factor, or fails to take account of the latest technology in its own branch of the business, is doomed to disappointment. The country will demand, and undoubtedly will have the benefit of, the best in technology for production of fixed nitrogen at a minimum cost; and moreover the country will see to it that the use of fixed nitrogen in agriculture is extended to the point of maximum efficiency. The laggard in technical affairs is the one who will suffer.

The Annual Report of The Steel Corporation

AS THE United States Steel Corporation reports its earnings quarterly, the 1921 profits have been known for a couple of months, but the annual report, which has just been issued, offers a better opportunity for their study. After allowance for federal income and all other taxes, subsidiary company depreciation charges and general administrative expenses, but before payment of either subsidiary company or Steel Corporation bond interest, the corporation's total earnings amounted to $100,791,279 in 1921, as against $185,095,359 in 1920. The shipments of rolled steel, etc., decreased 43.5 per cent in tonnage, and realized prices decreased greatly, while the reported earnings decreased 45.6 per cent.

This decrease in earnings by comparison with reports made by the majority of independent steel companies is considerably less than would be expected. In some quarters the impression has grown up that "the independents" are at a great "disadvantage" as compared with the Steel Corporation, this alleged disparity accounting for the Steel Corporation reporting earnings while most of the independents report losses. That impression is incorrect. There are several ways by which this can be shown. Perhaps the most interesting is to note that in 1912 and 1913, years in which the Steel Corporation and the independents alike had satisfactory profits, the Steel Corporation's earnings were about $10 per ton of steel shipped. If the typical independent was at a disadvantage as compared with the corporation, the disadvantage could have been no more than a very few dollars a ton. The same number of dollars per ton would not account for the disparities shown in 1921 earnings, while of course there has been no great change since 1912 in the relative positions, as to manufacturing processes used or character of physical equipment.

The divergences are due almost wholly to two things —to a difference in accounting methods and to the Steel Corporation having acquired certain good will in 1920 by holding down its prices, whereby it operated to better advantage in 1921 than did the majority of the independents.

As to accounting methods, it may be remarked that if the Steel Corporation desired the general public to be in ignorance of its financial affairs, as used to be the case with nearly all large corporations, its practice of publishing a full report annually would be a noteworthy application of practical psychology. The Steel Corporation reports are studied by only a very few. As to difference in accounting methods, many corporations, whether in the steel business or not, considered their profits for several high price years, through 1920, as real profits, and in 1921 they were forced to make extensive inventory readjustments, whereby the profits of the good years were left unduly swelled and the profits of a lean year were diminished, sometimes beyond the vanishing point. The Steel Corporation's reserves against inventory were as follows at the ends of the years named:

1916.....	$13,524,794	1919.....	$90,000,000
1917.....	30,270,670	1920.....	95,000,000
1918.....	51,289,603	1921.....	60,710,255

This reserve is of course a continuous fund, rising or falling. When it rose, the corporation was refraining from declaring profits the existence of which it doubted. When the reserve fell $34,000,000 in 1921 this did not represent a padding of profits. The actual profits were simply permitted to stand. If inventory values had never fallen, after Dec. 31, 1920, the corporation would have been forced some day to declare that in the past it had earned $95,000,000 more than it thought it was earning. As it is, the corporation does not need to report that it made any such mistake.

The Mental "Feel" Of the Nature of Matter

ON ANOTHER page of this issue a member of our staff presents a digest of some current thought about the structure of atoms and their occasional isotopes. As in an earlier exposition of the Langmuir postulates, Dr. HENDRICK has not attempted to depict the intricacies of the heavier elements. They are still in that realm of supercomplexity for which the art of exposition seems not yet developed. Even in considering the elementary details there are dicta which seem likely to need an appetizer for the processes of mental digestion, such as the decrease in the weight of protons by a "packing effect" and the nature of the mass of electrons.

In a late number of our excellent contemporary *The Chemical Age* of London (vol. 6, p. 136, Jan. 21, 1922), Dr. STEPHEN MIALL in his "Notes on Some Recent Chemical Theories" says:

> It is not clear . . . why iron, with eight external electrons, should be chemically active while argon and xenon, with eight external electrons, should be inert. LANGMUIR has put forward an ingenious theorem to account for this and some other anomalies, but I will not try to explain it here. When I read his own words I think I understand and I accept his hypothesis, but when I try to put it into plain language I am not sure whether I understand it at all. It may be that future researches will make it easier for us ordinary people to grasp the difficult features, and until then the only way to cover up our lack of intelligence is to assume that we and our readers understand it and that we could put it into simple language if we took the trouble. The Athanasian Creed requires intellect with a similar attitude.

Our author calls a halt somewhat earlier in the game than does Dr. MIALL. He knows that we are strictly undenominational in religion, so that creeds are forbidden subjects, while as for the structure of atoms and isotopes of the higher atomic numbers, he declares he would need weeks of work by LEFFERT LEFFERTS in the preparation of his illuminating atomic models and then many hours of patient instruction from Dr. LANGMUIR himself.

What the author has tried to set forth in the present essay is something to give old chemists and engineers who have not followed the modern literature of physical chemistry the feel of the thing in their minds.

Readers' Views and Comments

Utility of Recrystallization Studies

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to the very interesting paper by Jeffries and Archer on "Grain Growth and Recrystallization in Metals" and particularly to the diagrams showing the effect of annealing on grain size of cold-worked material,[1] I wish to call attention to the fact that it is very useful to show such "recrystallization diagrams" in three dimensions: One to express the percentage of deformation in previous cold work, the second to show annealing temperatures and the third to show grain size.

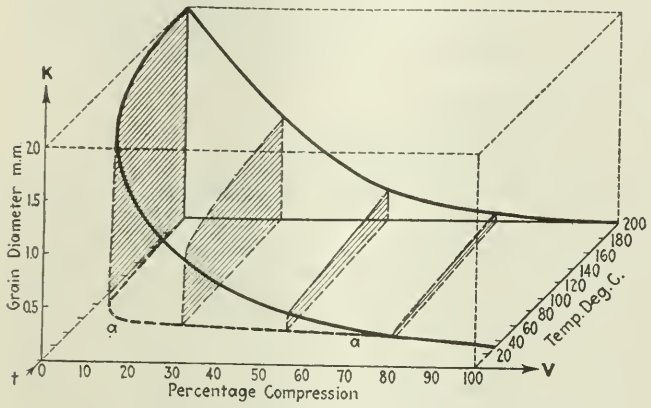

FIG. 1—RECRYSTALLIZATION DIAGRAM FOR TIN, ACCORDING TO CZOCHRALSKI, 1916

This form of diagram, worked out for tin by Czochralski,[2] is shown in Fig. 1.

In this diagram the principal horizontal axis represents the degree of cold work which the material has undergone (for instance, the percentage of reduction of height of a cylinder under compression), the secondary horizontal axis represents the temperature to which the sample was then heated, while the ordinate is the diameter of the grain after recrystallization. If the sample is reheated to a temperature below the curve *a-a*, no change in the grain size takes place.

[1] CHEM. & MET. ENG., March 1, 1922, vol. 26, pp. 405-408.

[2] Czochralski, Grundprinzipien der technologischen Kornverfeinerung; Forschungsarbeiten auf dem Gebiete des Ingenieurwesens, August, 1919.

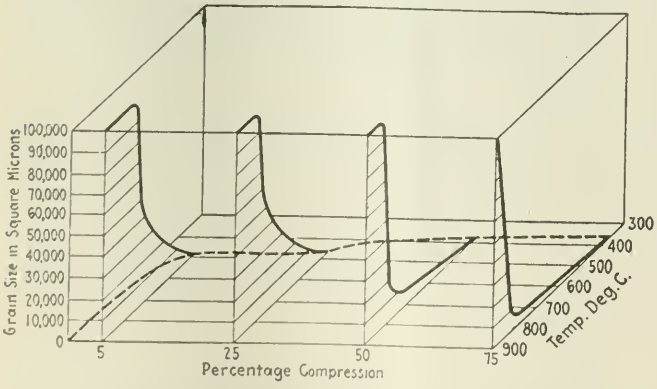

FIG. 2—RECRYSTALLIZATION DIAGRAM FOR ELECTROLYTIC IRON, ACCORDING TO OBERHOFFER AND OERTEL, 1919

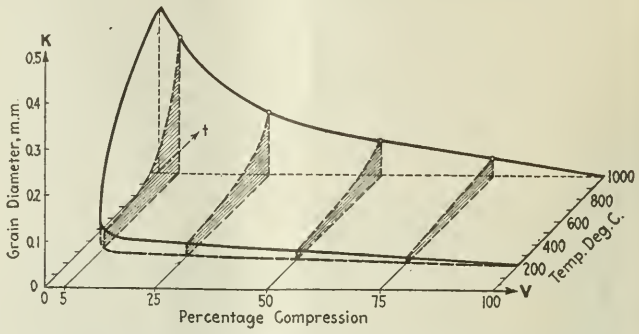

FIG. 3—RECRYSTALLIZATION DIAGRAM FOR COPPER, ACCORDING TO RASSOW AND VELDE, 1920

Above this lower temperature limit, however, the grain soon acquires the average size indicated. As will be seen from the other diagrams, the "body" of the diagram always flattens out with increased degree of cold work—i.e., the grain size of cold-worked metal increases with increasing the recrystallization temperature, but decreases with the degree of cold work.

The phenomena and laws of recrystallization will be of increasing importance to metallurgical investigation, and they are also bound to be of great practical value to future workers.

After the recrystallization diagram of a metal or alloy is once worked out, it is possible to determine the degree of cold work a material had previously undergone, by heating it to a certain temperature and measuring the grain size. The diagram will then reveal the desired information. In a similar way the grain size can

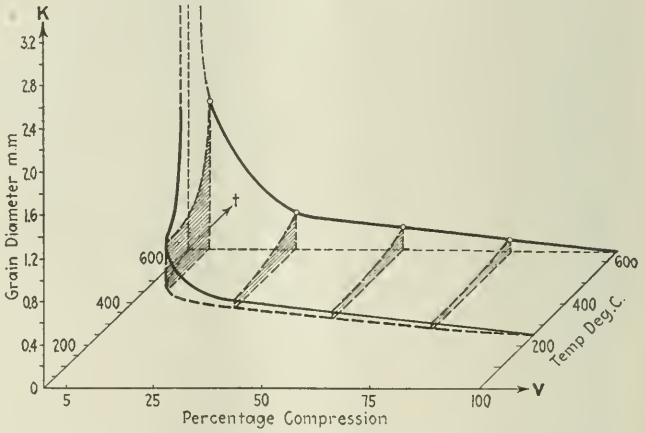

FIG. 4—RECRYSTALLIZATION DIAGRAM FOR COMPRESSED ALUMINUM (98.5 PER CENT), ACCORDING TO RASSOW AND VELDE, 1921

be utilized as criterion of the temperature at which cold-worked metal has been annealed. To do this, the metal is subjected to increasing temperatures until the grain size increases. This temperature must necessarily be higher than the previous annealing temperature. By measuring the grain size produced by the final treatment we can find from the diagram the degree of cold working, and by considering the grain size of the material as delivered we can then ascertain the original

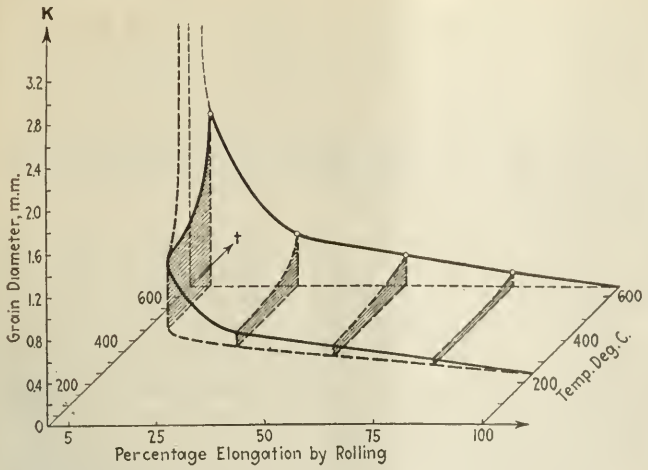

FIG. 5—RECRYSTALLIZATION DIAGRAM FOR ROLLED ALUMINUM (98.5 PER CENT), ACCORDING TO RASSOW, 1921

annealing temperature. By choosing a suitable degree of cold work and a suitable anneal we would be able to produce any desired grain size—in other words, we are enabled to put the metal systematically into a definite physical and mechanical state.

The practical application of these important theoretical considerations is limited mainly by the small number of such recrystallization diagrams which have been worked out so far. As far as I know, they have been published only for tin (Fig. 1), electrolytic iron (Fig. 2), copper (Fig. 3) and aluminum (Figs. 4 and 5). The difference between Figs. 4 and 5, although small, shows that it is advisable to control the manner in which deformation by cold work was produced.

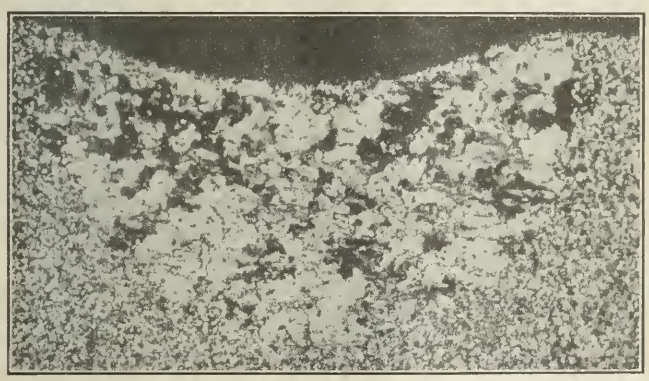

FIG. 6—BRINELL TEST, STATIC LOAD; ANNEALED AT 750 DEG. C. × 15

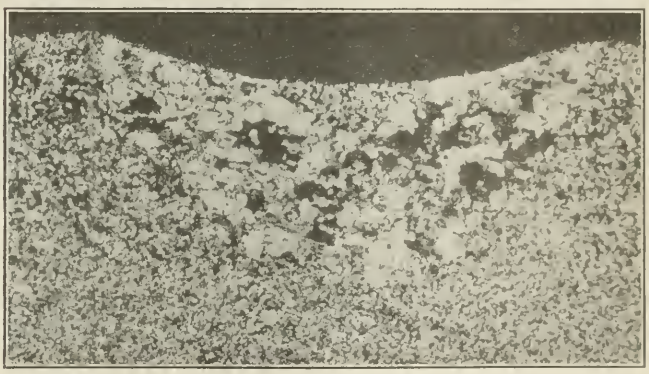

FIG. 7—SAME IMPRESSION AS IN FIG. 6, PRODUCED BY IMPACT; ANNEALED AT 750 DEG. C. × 15

The recrystallization diagram of iron differs from that of tin in one point: Heavy cold work does not increase the grain size with increasing annealing temperature first quickly and then slowly, but in opposite manner.[3]

It will be extremely valuable, both from a scientific and technical point of view, to have such recrystallization diagrams carefully worked out for the most important metals and alloys, especially for those used to a large extent in the industries. Further development along this line will help make the science of metallography available for "quantitative" work, a movement which was originated years ago by Dr. Jeffries and for which much credit is due.

Furthermore, recrystallization studies can doubtless be applied to advantage when investigating strains produced in specimens that have undergone tensile, bending and other mechanical tests. Or, in the diagnosis of failures, recrystallization upon annealing will give the clue as to whether fracture was due to the application of excessive static forces, impact or to faults in chemical composition. For instance, in a recent investigation of the comparative resistance of metals to ball indentations under static and kinetic forces, Wüst and Bardenheuer[4] utilized the recrystallization of strained metal to excellent advantage. They produced ball impressions of equal depth in low-carbon steel by static pressure and by impact; the specimens were then annealed for 1 hour at 750 deg. C. In this way recrystallization was obtained in that zone of the metal in which the cold work had reached a critical degree. Fig. 6 shows a static ball impression (Brinell), while Fig. 7 represents an impression of equal size obtained by impact of a 10-mm. ball.

As will be seen from these illustrations, the zone of coarse grain is much deeper in the impressions produced by static pressure than in those produced by impact.

Relation Between the Composition of Vapor and Liquor in Distillation

To the Editor of Chemical & Metallurgical Engineering

Sir:—In the number of your paper dated Feb. 15, 1922, there appears an article by Emil Piron on the fundamental laws of distillation. This article is open to serious criticism.

All of the material on page 317 except Table I was developed by Lord Rayleigh and published in the *Philosophical Magazine*, series 6, vol. 4 (1902), p. 521. It was later published in another form by W. K. Lewis in the *Journal of Industrial and Engineering Chemistry*, vol. 1, p. 522 (1909). It has also been discussed by me in my recent book on Distillation (McGraw-Hill, 1922).

The first column of page 318 is taught to the students of most universities in their courses in physical chemistry in the third or fourth year, the first part being due to Francis Marie Raoult, professor of chemistry at Grenoble, France, who published it in 1881, and the second to John Dalton in 1808 (Moore's History of Chemistry, McGraw-Hill, 1918).

I have no criticism of the remainder of pages 318 and 319, except that like all empirical relations its value is doubtful. The final material on page 320 will be

found, except for the specific application, in Lewis' article and in my book.

The reason I object to the publication of such an article is because the average young chemist or chemical engineer who has had a hard time mastering such fundamental laws as those of Raoult and Dalton while in college has discarded them as soon as he gets into the industries as being things impracticable for everyday use. And when such an article appears with those laws in perhaps an unfamiliar form and without the originators' names attached, so that they appear to be original with the writer, the former student infers that something new and also impracticable has been evolved, and hastily crosses over to the other side.

If, on the other hand, the writer had referred to the "well-known laws of Raoult and Dalton with which every one is familiar," and to the "fundamental work of Lord Rayleigh, known to all interested in distillation," he would have struck a responsive chord in the young man's mind, and stimulated the idea that perhaps there was something worth while after all in these old laws.

Transparent Films of Metal

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have noted at the bottom of p. 204 of the article "Colloidal State in Metals and Alloys" a statement about thin films of metal, which at once reminded me of A. E. Outerbridge's experiments, the results of which I saw in part in 1884, which were reported by him to the Franklin Institute on Feb. 27, 1877. Your readers would probably be glad to have the matter summarized from details Mr. Outerbridge will probably be glad to give or refer you to on Transparent Films of Metal. Instead of dissolving gold leaf, as did Faraday, he produced perfect and far thinner films of gold, silver, platinum and copper by electrodeposition and then solution of the metal receiving the deposit. I tried to get a film of iron to look through by deposition on fused AgCl (horn silver) and solution by NH_4OH, but it would not work and I have little chance for such interesting "things that don't pay" at once except in pleasure.

Bristol, Tenn. ASA W. WHITNEY.

To the Editor of Chemical & Metallurgical Engineering

Sir:—I have not had time to hunt up numerous old publications and notes requested by you covering my early investigations on extremely thin films of metal, but a communication dated April 5, 1895 (vol. 34, p. 67) to the American Philosophical Society by the late Patterson Du Bois refers to several early notices of the process and product. I quote:

"*Transparent Gold.*—In the course of a lecture on gold, delivered before the Franklin Institute on Feb. 27, 1877, A. E. Outerbridge, Jr., of the assay department of the Mint in this city, gave an account of some experiments he has made with the view of ascertaining how thin a film of gold was necessary to produce a fine gold color.

"The plan adopted was as follows: From a sheet of copper rolled down to a thickness of 0.005 in. he cut a strip 2½ x 4 in. This strip, containing 20 sq.in. of surface, after being carefully cleaned and burnished, was weighed on a delicate assay balance. Sufficient gold to produce a fine gold color was then deposited on it by means of the battery; the strip was then dried without rubbing, and reweighed, and found to have gained 0.1 grain, thus showing that 1 grain of gold can by this method be made to cover 200 sq.in., as compared to 75 sq.in. by beating.

"By calculation, based on the weight of a cubic inch of pure gold, the thickness of the deposited film was ascertained to be 1/980,400 in., as against 1/369,650 for the beaten film.

"An examination under the microscope showed the film to be continuous and not deposited in spots, the whole surface presenting the appearance of pure gold.

"Not being satisfied, however, with this proof, and desiring to examine the film by transmitted light, Mr. Outerbridge has since tried several methods for separating the film from the copper, and the following one has proved entirely successful.

"The gold plating was removed from one side of the copper strip, and by immersing small pieces in weak nitric acid for several days the copper was entirely dissolved, leaving the films of gold intact, floating on the surface of the liquid. These were collected on strips of glass, to which they adhered on drying, and the image of one of them is here projected on the screen by means of the gas microscope.

"You will observe that it is entirely continuous, of the characteristic bright green color, and very transparent, as is shown by placing this slide of diatoms behind the film. By changing the position of the instrument, and throwing the image of the film on the screen by means of reflected light, as is here done, you will see its true gold color.

"Mr. Outerbridge has continued his experiments, and, by the same processes, has succeeded in producing continuous films, which he determined to be as little as 1/2,798,000 in. thick, or 10,584 times thinner than an ordinary sheet of printing paper, or 60 times less than a single undulation of green light. The weight of gold covering 20 sq.in. is, in this case, 0.035 grain; one grain being sufficient to cover nearly 4 sq.ft. of copper."

In 1876 I furnished transparent gold films on glass for lantern projection to several universities and possess a note from Prof. Eggleston of Columbia dated Feb. 21, 1876, acknowledging receipt of one such specimen.

In one of my papers I referred particularly to Faraday's thin gold films, made by floating beaten gold leaf on a bath of potassium cyanide. I reproduced those, but found that all beaten gold leaf is full of holes and humps, as might be expected; my films were all continuous and of uniform thickness, as shown by their transparencies and faint green tint by transmitted light.

I never attempted to commercialize the patent (No. 198,209, granted Dec. 18, 1877), though I made a lot of gold foil, some thicker than gold leaf, and used these for various purposes.

One of the most interesting to me was a request from Prof. S. P. Langley for a gold strip to make the first "grill" or resistance bridge for an experimental instrument for measuring infinitesimal variations of heat from stars. This he called a "bolometer." I think the gold film or foil was too good a conductor for his purpose and I remember making one, or trying to, of palladium. All this was so long ago that I have forgotten most of it, but we had several talks and I visited him at his observatory outside of Pittsburgh on a spur of the Alleghanies.

Philadelphia, Pa. ALEX. E. OUTERBRIDGE, JR.

Atoms and Isotopes

A Record of Present-Day Conclusions as to the Structure of Atoms or Atomic Architecture and of the Nature of Isotopes, Including a Short Note on the Leading Contributions of Dr. F. W. Aston, Who Is Now Visiting America

By Ellwood Hendrick, Sc.D.
Consulting Editor, Chemical & Metallurgical Engineering

SOMEWHAT over a hundred years ago we—that is to say, we chemists of earlier date and personality—were discussing whether John Dalton was philosophically justified in his theory and whether an indivisible atom were possible or not. We were then, however, as we are today, leaders in pragmatism, and we welcomed then, as we do now, any theory that works. In this respect chemists differ from most physicists who have less urge to be practical, and thus occasionally there arise cleavages between them in habits of thought. The author of a text-book on physics, for instance, would hesitate long before presenting his readers with a two-dimensional exposition of the benzene ring. In chemistry we don't mind a little incongruity like that—so long as it works. And while the earlier generations of us continued to discuss the atomic theory in the abstract, we accepted it for the same pragmatic reason that we accept the benzene ring.

Dr. Prout and His Idea

Between 1815 and 1817 a London physician, Dr. William Prout, ventured the belief that the atomic weights of the different elements were whole numbers and that, hydrogen being 1, all the elements were aggregates of the atoms of primordial hydrogen. "Many tried to reconcile Prout's hypothesis with facts," says J. W. Mellor,[1] "by changing the standard of reference to something equivalent to half an atom of hydrogen, and then to a quarter of an atom of hydrogen. But having once begun to divide the hydrogen atom, there was no limit to the process of subdivision, and the hypothesis could then be made to fit any conceivable set of atomic weights. This tinkering with Prout's hypothesis brought it for a time into disfavor."

Stas of Ghent, a generation and more later, preceded our own Theodore W. Richards in the meticulously exact determination of atomic weights, and he found so many fractions, contradictory to the whole number hypothesis, that he said: "I have arrived at the absolute conviction, the complete certainty, so far as is possible for a human being to attain to certainty in such matters, that the law of Prout is nothing but an illusion, a mere speculation definitely contradicted by experience."

The Faith of Dr. Richards

Stas held the floor, and poor Prout was in limbo for many years after his death, languishing in that purgatory of chemistry to which all those are consigned who propound theories which are not accepted. Richards was not so drastic in his conclusions as was Stas. He took up the work where the Belgian left it off, and proceeded to record his findings, despite the fact that they did not seem to lead anywhere or suggest anything but to add more decimals. The writer remembers an evening about a dozen years ago when Dr. Richards was speaking in an informal manner to a meeting of chemists on the work being done in the Harvard laboratory. He said in substance: "Sometimes we are asked why we devote so much time to work that seems dull and that does not lead more directly to discovery. Our answer to that is that we are gleaning facts, which are duly recorded and made available to others. And in so doing we have in mind that what we do may become useful under greater enlightenment than ours. As yet these records are only so many figures, but under the illumination of a greater intelligence, of a master mind, probably with a mathematical background and a great capacity for co-ordination, they may be so arranged as to reveal what is still unknown. We are getting out stones against the time when the master builder shall come to build the temple."

It was something to that effect which he said in the vein of his usual modesty.

Chlorine's Short Career as an Oxide

Now we shall not go over the ground in reference to the theory that atoms were indivisible units of matter, except to say that most of us held in the backs of our heads reservations in regard to it. We claimed that atoms were the ultimate grains of matter—and then we were not so sure after all. The writer recalls also an evening at Zurich back in 1879 when Victor Meyer brought out his vapor density apparatus and explained his curious experience with chlorine at high temperatures; that not only did he find singular irregularities in the vapor density of chlorine, but on opening the apparatus, there developed unmistakable signs of oxygen where theretofore only chlorine was contained. There was scarcely a man present who was not willing to believe that the halogens were oxides of some primary or more nearly primary element. Later it was demonstrated that the oxygen came from rubber connections in the apparatus, but the incident is given to show how lightly chemists more than a generation ago held to the belief of the final integrity of atoms.

Persistence of the Higher Criticism

This question would not down. Most atomic weights constantly approximated whole numbers. In the International Table of Atomic Weights for 1912 there are 82 elements, and of these 39 are integers within one-tenth of a unit. Or, "If we consider only the elements whose atomic weights were determined by Stas, we find that two-thirds of them have atomic weights diverging

[1] "Modern Inorganic Chemistry," London, 1914, p. 816.

by less than one-tenth from whole numbers."[2] The approximation to whole numbers is greater if we consider oxygen as 16 than hydrogen as unity, but we shall not discuss that subject now.

Another disturbing feature was the family relationships exhibited in such elements as the alkali metals, the alkaline earths, the halogens, etc., and the similarity of their relationships to those among known organic bodies, such as methane, ethane, propane, butane, etc., with regular increases in molecular weights.

Again, if elements are independent entities, enduring from everlasting to everlasting without beginning and without end, why are close relatives so often associated with each other in nature? Why is silver found with lead and gold, selenium with the sulphur of pyrites, cadmium with zinc; and why do the rare earths and the platinum family almost always appear to be having a thanksgiving feast, with all branches united? Of course we can overlook or forget, but we cannot cut from the records old J. W. Doebereiner and his triads, even though he has been dead for nearly a hundred years—and the triads are definite groups. It was easy enough for London chemists to chortle and pooh-pooh Newlands into silence when he offered his theory of octaves, but after a while Mendeléef and Lothair Mayer took it up, and they built the periodic table; and then we couldn't throw it out of the house. The blamed thing was there. Prof. G. C. Foster had all sorts of fun with Newlands when he asked him if he discovered any coincidences by arranging the elements according to their initial letters, but in spite of all that it is just possible that Irving Langmuir's octet theory in regard to electrons in the presence of positive charges may light another candle at the shrine of Newlands, while Foster's acerbity loses its sharpness. More evidences of the unsoundness of the infinite and eternal theory of elements were developed from "the grouping of spectral lines, the perturbation of spectral lines, the phosphorescent spectra of the meta elements, stellar observations, electric discharges in attenuated gases, and radioactivity"[3]—more particularly in radioactivity.

The Wages of Modesty

Prof. Richards' modesty was excessive, because he himself within a few years helped to show deviations in atomic weights that finally upset the complacency of chemists whose faith still clung to the integrity of the atom. We must note also the contributions in this respect from Professors Soddy and Honingschmidt. It was the demonstration that the atomic weight of lead varies according to the source of its origin. "Radioactive lead" (which is not appreciably more radioactive than any other kind) from thorium differs from that from uranium, and both differ from ordinary lead.

Eventually, then, we had the disintegration of the radioactive elements on the one hand, and various kinds of lead with identical chemical properties, but different atomic weights, on the other. And so the great research as to the constitution of the atom began in many places. There was Sir J. J. Thomson, who discovered positive ray analysis, and Sir Ernest Rutherford, who, among many other things, drove hydrogen atoms from an atmosphere of nitrogen. Prof. W. D. Harkins of Chicago University propounded the theory that all other atoms than hydrogen and helium were made up of aggregates of atoms of hydrogen and helium, and the brilliant young Moseley of Cambridge University pointed out shortly before his death at Gallipoli that the atomic number of elements is of more fundamental importance than the atomic weight, and that the atomic number indicates the number of free positive charges on the nucleus, and consequently also the number of electrons held about it.

With such tunneling into the very foundations of our faith in the inviolability and invulnerability and immutability of the atom, it is high time to look around and take stock of what principles we have left over.

The Requirements of Faith

Some things we must take for granted. For instance, we must agree that the hydrogen ion is one single, positively charged particle. It is the universal positive charge. Its mass is 1. When this engages an electron, which it invariably does whenever it can, it becomes a hydrogen atom. The negative particle has about one eighteen-hundredth of the mass of the whole atom. The two parts are held in leash by their opposing electric charges, but they are not in contact. The nucleus is the positive charge and the electron whirls around or about it in some manner. The atom of every other element differs from the hydrogen atom only in the number of positive charges in the center or nucleus and the corresponding number and the arrangement of electrons outside of the nucleus, with more pairs of positive and negative charges packed in between them, as we shall describe later. Please accept as the workable theory and without further explanatory introduction, that all atoms are composed of a nucleus where the positive charges are concentrated and that around and about this nucleus there are an equal number of electrons or negative charges held in leash by these positive charges. The arrangement of electrons we have previously discussed in an introductory chapter called "The Langmuir Postulates," published in CHEMICAL & METALLURGICAL ENGINEERING, vol. 21, No. 2, July 15, 1919, and the study has since been greatly augmented and developed in various publications by Dr. Langmuir himself. This theory of place rather than of orbit for the external electrons finds favor with chemists because, chemically speaking, it works. The theory of Bohr, in which the electrons revolve as planets about a sun, is in favor with many physicists, but it does not make so clear to chemists the operation of chemical phenomena. We call these electrons external or free, and the positive charges in the nucleus free for reasons that we shall take up shortly. They are nevertheless in opposition and are held together by their opposing forces.

Please take for granted also the work of Moseley and admit that the atomic number represents the number of free positive charges in the nucleus and also that of the free electrons which rotate or are held about it. With few exceptions this atomic number indicates the place occupied by each element in the order of increasing atomic weights. Thus the atomic number of hydrogen is 1, helium 2, lithium 3, and so on up to uranium, the atomic number of which is 92, and which has the highest number as well as the greatest atomic weight of all the elements.

Then if hydrogen consists of one positive charge (or proton, as John Mills calls it) and one electron, and its atomic number is 1 and its atomic weight is 1, why are

[2] James Walker, "Introduction to Physical Chemistry," 1919, p. 19.
[3] Mellor, p. 817.

not all atomic weights and numbers the same, after all? Well they're not. We have a list of atomic numbers given before and approximate atomic weights given afterward as follows: 1 hydrogen 1; 2 helium 4, 3 lithium 7, 4 glucinum 9, 5 boron 11, 6 carbon 12, 7 nitrogen 14, 8 oxygen 16, 9 fluorine 19, 10 neon 20, 11 sodium 25, 12 magnesium 24, and we can go on until we find that the rule—which, according to the Sunday School hymn, "we may almost discover"—that the combining weights are approximately double the atomic number, is not a rule at all. We have, for instance, 50 tin 119, 78 platinum 195, 79 gold 197—indeed, the higher we go the more the atomic weights run away from us. So our only safety is to disabuse our minds of this conclusion. A positive and a negative charge together represent 1. Never mind the observation that the atomic weight of many elements represents about double the respective atomic number.

No, the atomic weight, we say, is made up of the atomic number, which is the number of positive charges or protons in the nucleus plus an equal number of electrons held in leash or revolving about the nucleus (the mass of the electrons being negligible)—and then something else. The atomic number would be the atomic weight if it were not for this something else.

Atoms Not Grains

Before approaching this feature let us make a few notes about these positive and negative charges in atoms —these protons and electrons. An atom is not a compact, tight grain. The actual space or displacement of the nucleus and several electrons of an atom, compared with the space inclosed by the orbits or positions of the outer electrons, is almost negligible. One evening at the Chemists' Club Dr. Irving Langmuir said (according to the writer's recollection, and he records his apologies if his memory is at fault or if Dr. Langmuir has since revised his opinion): "If we were to magnify the diameter of an atom to the length of a mile, the electrons would have a diameter of 5 ft. each and the nucleus would be the size of a walnut." This was merely an incidental remark, and the kind of atom referred to is not remembered, but it is given to indicate how much of energy and how little of substance we have in matter, as matter. Again, it is the positive charge that has weight or mass. We read that the electron has one eighteen-hundredth the weight of a hydrogen atom. Then if a hydrogen atom consists of one proton and one electron, it is the proton that furnishes the weight, not the electron. The electron of itself is without definite mass; its mass or weight is a function of the velocity of the electron and it is always negligibly small in comparison with the proton.

Atomic Numbers and Atomic Weights

Now let us approach the reason why the atomic weight is greater than the atomic number in connection with all other atoms besides those of hydrogen.

We have been agreed for a considerable time that there must be something else besides these free protons and electrons in the atom. Atomic weight demands it. Now it is held that the excess weight is due to exactly the same elemental stuff, to some more positive charges bound to electrons somewhere within the atom, and there has been considerable discussion as to the elemental forms in which they are bound. That is, what kind of small atoms are there within larger atoms to make up the difference between the atomic weight and the atomic number of each? In this connection opinion has followed the voluminous and persuasive arguments of Prof. Harkins of Chicago in support of the belief that the excess mass consists generally of helium and hydrogen atoms. The subject has an important bearing on the cosmic history of matter. From the study of the spectrum and the rotational velocities of certain nebulas, particularly the one in Orion, it is probable that a substance of elemental nature discovered there and which appears to have an atomic weight of 3 is the original material from which creation makes its start. It is called nebulium. It appears also that the next step in the cosmic order is the development of helium and hydrogen from nebulium, and that the synthesis of all other elements proceeds from hydrogen and helium. It opens up a vast field for study and speculation, but it will do no harm to reserve decision on this until we know more than we do now.

Atomic Architecture

As to the place within the atom where this excess of helium and hydrogen is held, theory has usually packed it within the nucleus along with the free positive charges, which are present in number equal to the atomic number of the element. But lately Sir Ernest Rutherford has proposed a three-stage atom, which is a more orderly arrangement and for which he makes an excellent argument in the light of certain phases of research. This excess weight, consisting of positive and negative charges, is packed more or less closely about the nucleus and is held there as satellites, much nearer than the outer free electrons which offset the free protons within the nucleus. This makes an atom of three stages, consisting of the nucleus of free protons at the center, next the satellites as bound protons and electrons (or as helium and hydrogen), and the free electrons beyond them. The free electrons on the outer shell are those which wander to and fro and which produce all chemical reactions.

As an example of the force needed to drive satellites of hydrogen from nitrogen atoms as achieved in Rutherford's experiment by the impact of alpha particles from radium C upon the nuclei of nitrogen atoms, it is computed that if the base of each impact were magnified to 1 cm. square, there would be a blow of 10^{27} in kilograms. That's a billion times a billion times a billion times 2.2 lb. and then a lot more, on something the size of a child's thumb nail.

Summary of the Atom

What we need to get into our minds now is that, in addition to the nucleus of every atom that holds as many free positive charges as are indicated by the atomic number, there are packed about the nucleus as many hydrogen and helium atoms as will make up the difference between the atomic weight and the atomic number. And beyond these are the free electrons of the atom that are held there by the force of the free positive charges in the nucleus. We must also remember that a positive charge counts as 1 in the atomic weight. Never mind about the fractions for the present. Also that the mass of an electron is relative to its velocity and that this is also, as mass, negligible. And finally that every atom contains the same number of electrons as it does of positive charges.

As an example let us consider an atom of tin as a

three-stage atom. Its atomic number is 50 and its atomic weight 119. Then there will be 50 free protons in the nucleus, what amounts to 69 hydrogen atoms packed about it, irrespective whether as hydrogen or as hydrogen and helium, to make up the atomic weight of 119, and 50 more electrons arranged in concentric shells on the outside, the mass of which we do not count.

The Obstreperousness of Hydrogen

Right here, however, we meet a difficulty. We have a mass of 16 for oxygen, but a little more than 1 for hydrogen. Or if hydrogen is unity, then we have a little less than 16 for oxygen. There isn't any getting around this discrepancy, either. If oxygen is 16, then hydrogen is 1.008. And since atomic weights approximate whole numbers more nearly with oxygen as 16 than with hydrogen as 1, we take oxygen as 16 and hydrogen as 1.008. That means that hydrogen atoms packed in or about a nucleus are 1 each, whereas by itself the mass of the atom is 0.008 greater. It is suggested that the increase in the single hydrogen atom is due to the lack of a "packing effect" of hydrogen and helium atoms squeezed together with great force within the nucleus or as satellites to it; that the same mass, under the packing effect of bound positive and negative charges, is 1, whereas free it is slightly more.

It is not very appealing, this theory that hydrogen and helium atoms or those positive and negative charges packed together about the nucleus of every atom should be 1, and 1.008 if free as in hydrogen itself, but let's accept it. It works out mathematically. And Mr. Aston said in his lecture at Columbia on March 15, according to the writer's notes, "By the conversion of hydrogen into helium the hydrogen loses mass of 0.008, but in doing so it generates energy. This is such that if one-tenth of the hydrogen of the sun were converted into helium it would provide for the sun's heat and light for 1,000.000,000 years."

Let's hope that no one will discover a method to accomplish this transformation for a long time to come. We are not good enough to wield such power. Indeed, if we started it we might not be able to stop it—and then where should we be? As Dr. Aston says, the result would probably be signified to the universe as a new and very bright star.

Dr. Prout's Ghost

It is well to bear in mind that the nucleus is the less studied and less familiar part of the atom, and therefore it is the more abundant field for theory, for empiricism and for the joyful art of postulation. It may be indeed that we are dealing with entities over in the realm to which Sir Evelyn de la Rue refers as "beyond numbers"; like the velocity of light, which remains constant from an approaching and from a retreating body. Sir Evelyn intimates that we might call this realm infinity, being not only beyond numbers but beyond us as well. There are Hottentots who can count up to 20, but 21 and all numbers beyond that are "many." It may be that the velocity of light and the mass of the electron will be our limit, our 21, our many, our infinity.

Now, leaving that difficulty aside, with hydrogen composed of one proton and one electron and with helium composed of two protons, two electrons and two hydrogen atoms packed inside, and with everything else made up of just such protons and electrons and hydrogen atoms, can't you see the shade of old Dr. Prout looming up again in the offing?

Isotopes Explain the Fractions

Nothing yet mentioned, however, even if we leave hydrogen out of consideration, will explain the persistent fractions in atomic weights, small though most of them are. We are postulating integral numbers for atomic weights—and they are not there. But the greater illumination which Dr. Richards was waiting for comes in good part from himself. These isotopic forms of lead point the way. If different atoms of the same element have different atomic weights but similar chemical reactions, they are isotopes. Thus we have lead atoms with the same number of free positive charges within and of electrons without the nucleus, but with a varying number of these bound sub-atomic couples or positive and negative charges packed about the nucleus. Isotopes are atoms which have the same atomic number—that is, the same number of free positive charges within the nucleus and opposed electrons outside it—but not the same number of hydrogen or helium atoms packed about the nucleus. Therefore the atomic weights of isotopes differ. And while each atom is integral, mixtures of isotopes give fractional weights. Even if we had equal portions of actinium lead 206, common lead 207, thorium lead 208 and radium lead 210, we should have an atomic weight of the mixtures of 207.5 and there is nothing to make the proportions of the different isotopes either constant or equal. So we generalize by saying that fractions in atomic weights are due to mixtures of isotopes—and then set out to prove it.

We must beware not to confuse isotopes with allotropic modifications such as is shown in the various forms of phosphorus and sulphur. There we have different geometrical arrangements of atoms within the molecules or crystals. In isotopes the differences are confined to the packing about the nuclei of the atoms. And we must not confuse the presence of isotopes with processes of radioactivity. When free positive charges and entrained electrons are thrown from a radium atom, for instance, the atomic number is reduced, and we have the transmutation of an element, the new element ceasing to be isotopic with the first.

It stands to reason that all the various isotopic forms of lead have the same chemical properties, because chemical properties are on the outside of the atom. We have in chemical activity exchanges of electrons on the outer shells of atoms, the holding of pairs of electrons in common by combined atoms and the wandering of electrons from one atom to another, thus producing ions, but in chemical processes the free positive charges in the nucleus and the H and He atoms packed within or about it are not disturbed. In radioactivity they are shot off, but not in chemical processes. So it is generally agreed, and it would seem fair to say, that the chemical properties of all the isotopic variations of an element are the same.

The Bell Rings

Having written the foregoing, the bell rang for luncheon. On the dining-room table I found my weekly copy of *Science*, vol. 4, No. 141, of Jan. 13, 1922, and there on page 42, under the head of "Scientific Events," I read that among the grants made by the Heckscher Research Foundation at Cornell University was one to

"Prof. L. M. Dennis for carrying on an investigation on the 'Separation of the Isotopes of Lead by Chemical Processes.'"

Right here is the text of as pretty a sermon in science as one could want to preach. Suppose there were a hierarchy of chemistry and we wore our academic vestments—on our minds as well as on our bodies—every day, and were insistent that we maintain unity in all the essentials of belief, restricting liberality to what we determine to be non-essentials. Then we should proceed to try Dr. Dennis for heresy and make things as uncomfortable for him as we could. But this will not do within the realm of science. If we maintain that the isotopes of an element are chemically the same, and he undertakes to separate them by chemical means, the worst we can do to him is to wait until he comes out with his findings, and then argue with him if we do not agree with his conclusions. It is a good thing for us that this is so. In the meantime let us cling to the dictum that the isotopic varieties of lead are, chemically speaking, the same, until he disproves it. We need the foundations of faith, even if they are frail.

There is no reason why atoms of different elements should not have the same mass or atomic weight, and indeed this is so, especially among the heavier elements. For instance, radium D, actinium C and polonium all have the atomic weight of 210, but have as atomic numbers respectively 82, 83 and 84. These are not isotopes. They are called isobares.

Aston's Great Work

Very important in the field of isotopes is the work of Prof. F. W. Aston of Cambridge University. He tried in 1914 to break up a gaseous element that shows a considerable deviation from an integral number in its atomic weight, and began with neon, using diffusion methods. He believed it consisted of mixed isotopes of atomic weights 20 and 22, and his experiments confirmed him in this belief. The method of diffusion is very slow, and he followed this work by the use of Sir J. J. Thomson's method of positive ray analysis, and he then brought out the amazing conclusions that no fewer than twenty elements consist of mixed isotopes the mass of each of which is invariably a whole number. A memorandum of these may be of interest.

Element	Atomic No.	Atomic Wt.	Minimum Number of Isotopes*	Masses of Isotopes in Order of Their Intensity*
H	1	1.008	1	1.008
He	2	3.99	1	4
B	5	10.9	2	11, 10
C	6	12	1	12
N	7	14.01	1	14
O	8	16	1	16
F	9	19	1	19
Ne	10	20.2	2	20, 22, (21)

*Numbers in brackets are provisional only.

Lithium proved to be a mixture of isotopes 6 and 7. Sodium is simple, apparently only of 23. Potassium shows a strong line at 39, and a weak one at 41. Rubidium shows two, at 85 and 87 respectively. Although the atomic weight of caesium, 132.81, indicates complexity, no line except that at 133 has been distinguished.

Prof. W. D. Harkins undertook the search for isotopes of chlorine, the atomic weight of which remains persistently around 35.5 and has always stood in the way of any hypothesis of integral weights. He used the diffusion method, and described it in the *Journal of the American Chemical Society*, vol. 43, No. 8, August, 1921. Since the speed of diffusion varies inversely as the square root of the density, it stands to reason that by shooting Cl, for instance, through a porous material, the lighter isotopes, if present, will tend to pass through more rapidly than the heavier. And the fruit of 7 years' labor is confirmatory of this. Repeated experiments showed the remaining chlorine which did not pass through the porous material to increase in atomic weight in the measure of 0.0318.

His first effort at separation was by means of a centrifugal machine, which was unsuccessful, but by employing diffusion apparatus, using churchwarden pipe stems and special tubes of clay, a separation of chlorine into heavier and lighter fractions was accomplished. He calculated the proportion of isotopic chlorine having the atomic weight of 37 derived from the pure HCl which he put through the apparatus to be 23 per cent.

Another lead of research has been contributed by Brönsted of Copenhagen, who evaporated mercury in vacuo upon a surface cooled by liquid air. It stands to reason that the lighter atoms which are single in mercury vapor would evaporate more readily and condense on the cool surface, and he actually found that the density of the condensed fraction was slightly less than the residue.

Present-Day Conclusions

The theoretical conclusions of today in regard to atoms and isotopes are:

1. A positive charge of proton with or without an associated electron has an atomic weight of 1, excepting hydrogen, which is slightly above unity.

2. Counting oxygen as 16, every other atom after hydrogen has approximately an integral atomic weight.

3. In the nucleus of every atom are free positive charges in number equal to the atomic number of the element. These hold in leash, either as planets revolving or within circumscribed spaces in relation to the nucleus but exterior to it, an equal number of electrons.

4. Just outside the nucleus, according to the theory of Sir Ernest Rutherford, or within it, according to the earlier theory, of each atom of elements of higher atomic number than hydrogen is the packing. This consists of bound positive and negative charges probably in the form of helium and hydrogen atoms, which affect the atomic weight, but do not affect the chemical reactions of the atom. The presence of the packing explains the excess of the combining weight of atoms above their respective atomic numbers. It also explains the presence of isotopes.

5. Fractions in atomic weights are due to the presence of isotopes in varying proportions.

In the preparation of the foregoing essay I have drawn indiscriminately on the work of Rutherford, Langmuir, G. N. Lewis, Aston, Harkins and others, without attempting in every instance to ascribe credit to the respective authors according to the contribution of each. And I desire to acknowledge the clear illumination and kindly criticism of Prof. James Kendall of Columbia University, without whose aid I should have been unable to make the present contribution.

Contributions to the Study of Ammonia Catalysts—III

Description of the Apparatus Developed by the Fixed Nitrogen Research Laboratory for the Moderate-Scale Testing of Ammonia Catalysts at One Hundred Atmospheres Pressure*

By R. S. TOUR

IN A preliminary study of substances likely to be effective in catalyzing the formation of ammonia from nitrogen and hydrogen, much information can be secured by simple tests carried out at atmospheric pressure, as described in the first article of this series. Much more exhaustive tests can be carried out satisfactorily on a small scale at higher pressures by the use of such an apparatus as that previously described in the second article of this series.

However, in order to be able to decide finally on the selection of a catalyst for actual plant operation, it is essential that tests be also carried out in an apparatus of reasonably large capacity, capable of operating under conditions similar to those apt to prevail in the plant. From an apparatus of this type information may be obtained which is much more directly applicable to plant operation than that obtainable from a smaller apparatus.

Since the effective life of a catalyst is an important item in plant operation, especially in a high-pressure system where renewals are apt to be inconvenient and expensive, and since the reliability of catalyst tests depends greatly on their continuity, it is important that the testing apparatus be capable of continuous operation over long periods of time.

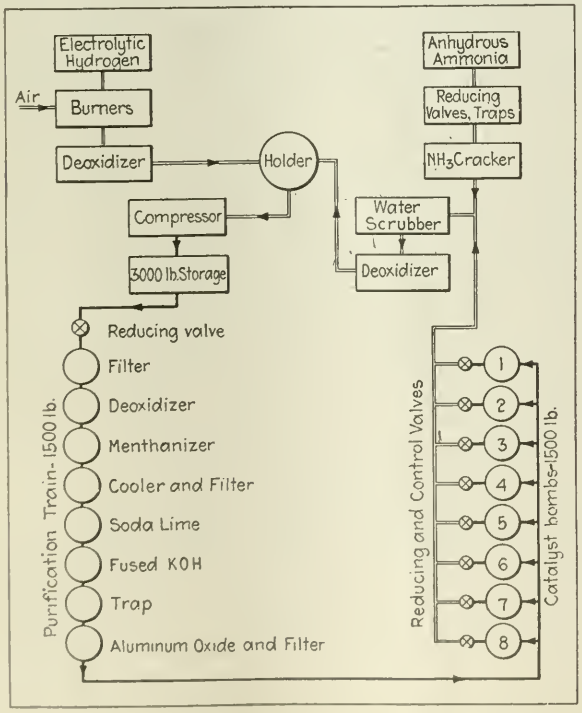

FIG. 1—FLOW SHEET OF CATALYST-TESTING PLANT

This report discusses a testing plant of the type indicated above, operated at the Fixed Nitrogen Research Laboratory. Such a plant presents many difficulties in design, construction and operation, and in its development it is inevitable that changes should be made from time to time in many items. In the main the description of apparatus is confined to the present installation and operation of the testing plant, although reference is made to apparatus and practices once employed but later modified or abandoned.

A critical study of the problem as a whole is not attempted, and therefore criticism of or comparison with other methods of achieving the same end is not included. It may be noted that the plant has to all intents and purposes operated continuously for over a year.

Early in 1916 the Bureau of Soils of the Department of Agriculture began a study of the ammonia synthesis problem and by 1917 the installation of a catalyst-testing plant was under way at Arlington, Va. In 1918 this testing plant was taken over by the Nitrate Division of the Ordnance Department, U. S. Army, and operated and developed through funds of the War Department in co-operation with the Bureau of Soils. In August, 1919, shortly after the creation of the Fixed Nitrogen Research Laboratory by the Nitrate Division, all the Arlington equipment was transferred to that laboratory.

Outline of Complete Installation

Since the detailed discussion of individual units may make difficult the visualization of the plant as a whole, a brief preliminary description of the complete set-up will be given, illustrated by flow sheets (Fig. 1) to which reference should be made in conjunction with the text.

The mixture of nitrogen and hydrogen (1:3) for testing is obtained from cylinders of liquid NH_3 which is decomposed after expansion to atmospheric pressure by being passed through a "cracker" containing electrically heated steel wool, then through a water scrubber and then through a deoxidizer of heated copper, from which it passes into the low-pressure gas holders.

From the gas holders the gas goes to compressors and is compressed to 3,000 lb. into high-pressure storage cylinders. From these cylinders it passes through an automatic reducing valve into the purification system, maintained at 100 atmospheres and consisting of a filter of glass-wool; a deoxidizer of copper, maintained at 300 to 400 deg. C.; a nickel catalyst maintained at 250 to 300 deg. C.; a water-cooled condenser and glass-wool filter; a soda-lime drier; a fused KOH drier; a dust trap; an Al_2O_3 absorber and glass-wool filter combined.

From the purification system the gas passes to the

electrically heated catalyst bombs, from which, after reduction to atmospheric pressure by appropriate valves, it passes through flowmeters, at which point samples for analysis are taken. The catalyzed gas issuing from the flowmeters passes through water scrubbers to remove the ammonia and thence back to the low-pressure gas holders for recirculation through the system.

The construction and operation of each of these items is discussed below.

Sources of Nitrogen: Hydrogen Mixtures for Testing

Up to the present the two gases have always been obtained together in the proportions desired for testing by decomposing ammonia. This is readily accomplished and yields a gas comparatively free from many impurities. Furthermore, it obviates the necessity of measuring and mixing the two gases independently.

As a future development, fifteen Electrolab cells are being installed to supply electrolytic hydrogen into which air will be injected in the proper proportion to form any desired ratio of hydrogen to nitrogen after deoxidation in a suitable apparatus.

Ammonia Cracker

Ammonia gas at atmospheric pressure obtained by expansion from standard liquid ammonia in cylinders is passed through the cracker, the final design of which

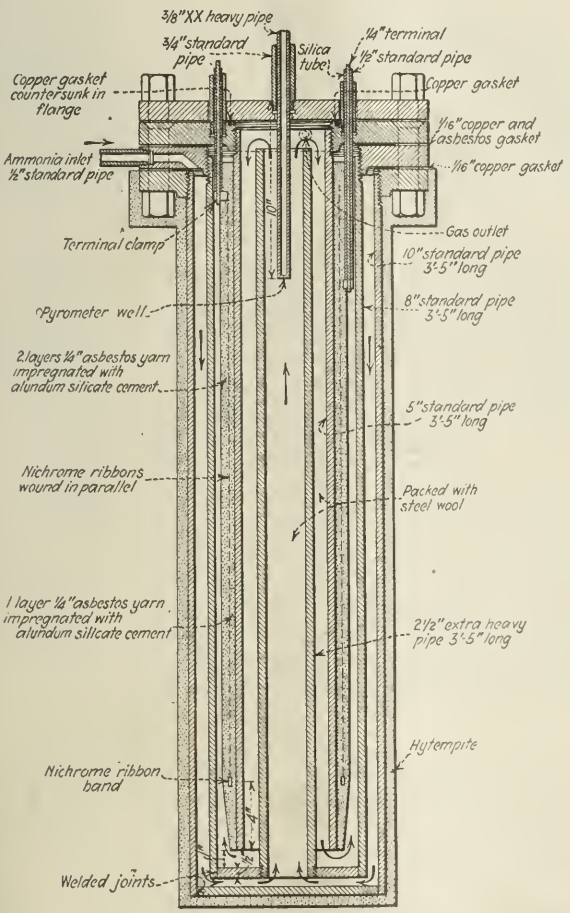

FIG. 2—THE AMMONIA CRACKER FOR EXPERIMENTS AT 100 ATMOSPHERES PRESSURE

is shown in Fig. 2. It is similar in principle to that described for small-scale testing in the first article of this series and consists essentially of four concentric steel cylinders, 10, 8, 5 and 2½ in. in diameter, arranged as shown in the figure, and all imbedded within a sheet-iron container 3 ft. in diameter, filled with 85 per cent magnesia. Around the 5-in. cylinder a heating coil of nichrome ribbon is wound, imbedded in alundum cement. The 5-in. and 2½-in. cylinders are packed with steel-wool and a pyrometer well of ⅜-in. XX heavy pipe extends into the 2½-in. cylinder. The whole apparatus is constructed of standard pipe fittings and so arranged that the heating element can be removed for repair without completely dismantling the outer shell. The ammonia gas enters at the top, passes down between the 10-in. and 8-in. cylinders for heat interchange, then up through the 2½-in. cylinder, where cracking begins, then down between the 5-in. and 2½-in. cylinders, where cracking is completed and last up and out between the 5-in. and 8-in. cylinders. The cracker operates at 600 to 700 deg. C., the heating coil taking 25 to 40 volts alternating current. The capacity is about 3 cu.ft. of cracked gas per minute. Two such crackers are maintained, one for continuous use, the other as a spare. The exit gas, containing about 0.1 per cent undecomposed ammonia, is scrubbed with water in a tower 8 in. in diameter by 6 ft. tall, packed with broken rock, the water flowing downward and the gas upward through the packing, finally leaving the tower with no ammonia remaining.

The Deoxidizer

From the scrubbers the gas may be passed when desirable through a low-pressure deoxidizer. This is essentially a piece of 4-in. standard iron pipe, filled with copper shavings and heated by a nichrome coil wound on the outside of the pipe and imbedded in alundum cement. This pipe is inclosed within the same heat-insulating shell with the cracker. The copper is kept at 300 to 400 deg. C., which suffices to reduce the oxygen content of the gas to traces.

Low-Pressure Storage

The nitrogen: hydrogen mixture, free from ammonia and practically so from oxygen, is metered by standard dry meters and a friction tube flowmeter for control purposes and goes to the holders. There are three single-lift, water-sealed, commercial gas holders, located just outside the building and fitted with heating coils to prevent the water from freezing. Two of these holders have a capacity of 500 cu.ft. each, and the third has a capacity of 250 cu.ft. All of the low-pressure gas lines to and from the holders and manifolds are of standard 2-in. and 1½-in. pipe and fittings, provided with traps, drips and drains, and tested for leaks at 30 lb. pressure.

Compression of Gases

The compressing system consists of three motor-driven standard four-stage, 4,000-lb. Norwalk compressors, two of them having 8 cu.ft. displacement per minute and one having 28 cu.ft. displacement. On the suction line to each compressor is a 10 cu.ft. tank which acts as a buffer and which is provided with an automatic vacuum alarm, warning the operator when the inlet line is under vacuum, with the attendant possibility of air being sucked into the line. The compressors, after some initial difficulties, have operated fairly satisfactorily, though requiring very careful attention and maintenance.

On its way to the storage system the compressed gas passes through a trap built up of a heavy steel cylinder

about 20 in. long by 5½ in. external and 4 in. internal diameter, fitted at each end with square forged flanges and with special internal construction to separate oil and water which is periodically blown out through a valve at the bottom.

High-Pressure Storage

The high-pressure storage system consists of twelve steel cylinders, 1.6 cu.ft. capacity. Eight of these are connected into the same manifold, which in turn is connected through standard stop valves with two auxiliary manifolds, to each of which two cylinders are connected. The piping is so arranged that two, four, eight, ten or twelve cylinders may be intermittently filled to 3,000 lb. pressure. The automatic reducing valves, one of which is used continuously, the other being reserved as a spare, are so connected to the storage that gas may be delivered from any of the above combinations of the storage system directly to the purification system at 100 atmospheres, or when desired two of the twelve storage cylinders may be used on the low-pressure side of the reducing valve as part of the purification system to increase the capacity, thereby minimizing fluctuations in the pressure. The system is fitted with gages, oil traps, safety valves and the like to insure continuous dependable operation.

It may be noted that the high-pressure manifold and the pipes which carry the gas throughout the high-pressure system are made of special double extra heavy ⅜-in. welded pipe and many of the connections, tees, unions, etc., are specially made, although standard hydraulic fittings are used where possible.

Purification of the Gas

The most important feature of the plant, other than the actual testing of the catalyst, is the purification of the nitrogen:hydrogen mixture. In order to be able to

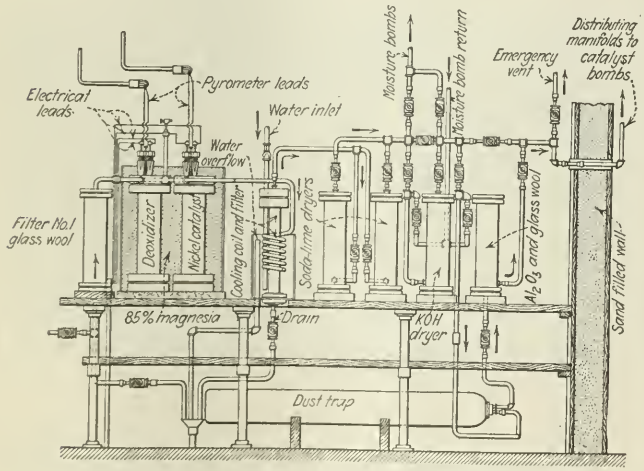

FIG. 3—PURIFICATION SYSTEM FOR EXPERIMENTS AT 100 ATMOSPHERES PRESSURE

draw intelligent conclusions concerning the behavior of the catalyst, it is essential either that the gas should be as pure as possible or that it should contain definite and known quantities of certain impurities when such are desired. The chief impurities likely to be present in gas cracked from commercial ammonia and scrubbed with water are traces of carbon compounds, moisture and oxygen, although removal of acidic constituents is provided for in the purification system. Carbon monoxide can scarcely be present in appreciable amounts, but the nickel catalyst provides for its removal.

The arrangements and connections of the various items of the purification system are shown in elevation in Fig. 3. Individual items will be discussed in more detail below.

Glass-Wool Filter

The gas from the storage cylinders passes at 100 atmospheres pressure into filter No. 1. This consists of a steel cylinder 5 in. outside diameter by 2 ft. long, fitted with flange heads and packed with glass-wool. The filter removes dust and oil which may have come over from the oil traps after the compressors.

Deoxidizer

From the first filter the gas passes to the deoxidizer, built up of a 2-ft. length of 5-in. double extra heavy chromium-vanadium seamless pipe and flanged at both ends with chromium-vanadium forged flanges. The joint used at the heads is a specially shaped tongue and groove fitted with copper gaskets. Within the deoxidizer is inclosed a steel tube carrying around it a nichrome heating element wound on alundum and incased in alundum cement. The tube is fastened to the head, which also carries the inlet and outlet connections and the electrical high-pressure terminals. The gas passes in through the head, down around the heating element and up through the steel tube, which is filled with copper turnings and maintained at 300 to 400 deg. C. The gas passes out through the steel tube through the head and to the next step of purification. Indications are that the oxygen escaping this deoxidizer is of the order of one part in one million. The deoxidizer is imbedded in 85 per cent magnesia inclosed within a sheet-iron casing. This same casing also incloses the next item of the purification train, the nickel catalyst.

Nickel Catalyst

The apparatus for the hydrogenation of carbon compounds is practically a duplicate of the deoxidizer above excepting that the inner tube carries a catalyst of reduced nickel on nonpareil brick and is maintained at 250 to 300 deg. C. The preparation of this catalyst was described in the first article of this series.

Cooler, Condenser and Filter

The hot gases pass from the nickel catalyst through a cooling coil of double extra heavy ⅜-in. pipe wrapped around a small cylindrical tower packed with glass-wool, the whole being immersed in a bath of cooling water. The gas passes down through the coil and up through the filter. The water formed in the deoxidizer is thus condensed and may be discharged through a drain at the bottom of the filter.

Driers

The gas next passes to a cylinder identical in design with the first filter of this train, filled with hard, granulated soda-lime. Two of these cylinders are arranged in parallel, but only one is in use at a time, the other being reserved as a spare. Removal of moisture as well as possible acidic impurities occurs at this point.

From the soda-lime drier the gas passes to a cylinder of similar construction, packed with lumps of fused KOH. Further removal of moisture and acidic impurities takes place in this cylinder.

From the KOH drier the gas passes into an empty steel cylinder of the type used in the storage system,

to serve as a settling chamber and to increase the capacity of the purification system to balance pressure changes.

Al_2C_3 Absorber

From the dust trap the gas passes into a cylinder similar in construction to those used as filters but containing a steel tube 2½ in. outside diameter by about 18 in. long, fastened gas-tight to the bottom head and open at the top. This tube is filled with granular colloidal Al_2O_3, which serves to remove moisture and any other readily condensible vapors, while the annular space around the tube is packed with glass-wool to act as a final filter, the gas passage being up through the Al_2O_3, down through the glass-wool and then directly to the catalyst bombs.

The arrangement of valves and pipes is so devised as to permit bypassing the gas around any unit of the purifying train when desired, and also taking off samples of gas for analysis at any point. As a matter of routine test a portion of the gas is bypassed from time to time, after the soda-lime driers and the KOH drier, through a special high-pressure bomb containing a weighed P_2O_5 tube by which moisture determinations are effected. This serves to determine the effectiveness of the preliminary drying and to indicate a need of replacing the soda-lime and KOH.

The Catalyst Bomb

The catalyst bomb represents the most important single item of the apparatus and the one whose construction and design present the greatest difficulties for successful operation. The assembled bomb, together with its heating element, is shown in cross-section in Fig. 4. Eight of these bombs are operated simultaneously.

The bomb proper is a chromium-vanadium steel cylinder, about 26 in. long by 5½ in. external and 4 in. internal diameter, fitted at each end with square chromium-vanadium flanges. The flange joints are made up with a specially shaped tongue and groove, copper gasketed joint that has proved very successful for high pressures and continually varying temperatures. The whole bomb is fastened securely to the floor for ease in assembly and is all incased in a sheet-iron container 16 in. in diameter, filled with 85 per cent magnesia.

The bottom flange is solid, while the top flange-head carries the three electrical leads to the heating elements and the catalyst tube through the center. The gas enters through the catalyst tube, which projects through the bomb head. The gas outlet from the bomb is through a passage drilled in the side of the head. On the under side of the head within the bomb is suspended the special heating element surrounding the catalyst tube.

The catalyst tube is a removable part of the bomb, permitting charging and recharging without disassembling. The portion of the tube extending above the bomb head carries a "T" connection for the gas inlet in the side and for the pyrometer well through the top. The pyrometer well consists of ⅛-in. steel tubing, which extends the full length of the catalyst tube within the bomb and permits the measurement of temperature throughout the full length of the catalyst. The catalyst tube within the bomb consists essentially of two parts, the upper portion being of steel packed with copper turnings to act as a "preheater" for the incoming gas before contact with the catalyst, and the lower portion a heavy-walled copper tube about 1 in. inside diameter which is charged with the catalyst. The copper casing aids in maintaining uniform temperature throughout the length of the catalyst.

The heating element consists essentially of a nichrome winding around a Pyrex glass tube of 1¼ in. outside diameter. The whole Pyrex tube and heating element is imbedded in alundum cement in a sheet-iron casing, which in turn is supported from the bomb head and held concentric with the catalyst tube which it surrounds. The gas passage is, therefore, down through the preheater, then through the catalyst, then up around the catalyst tube within the heating element and out through the bomb head.

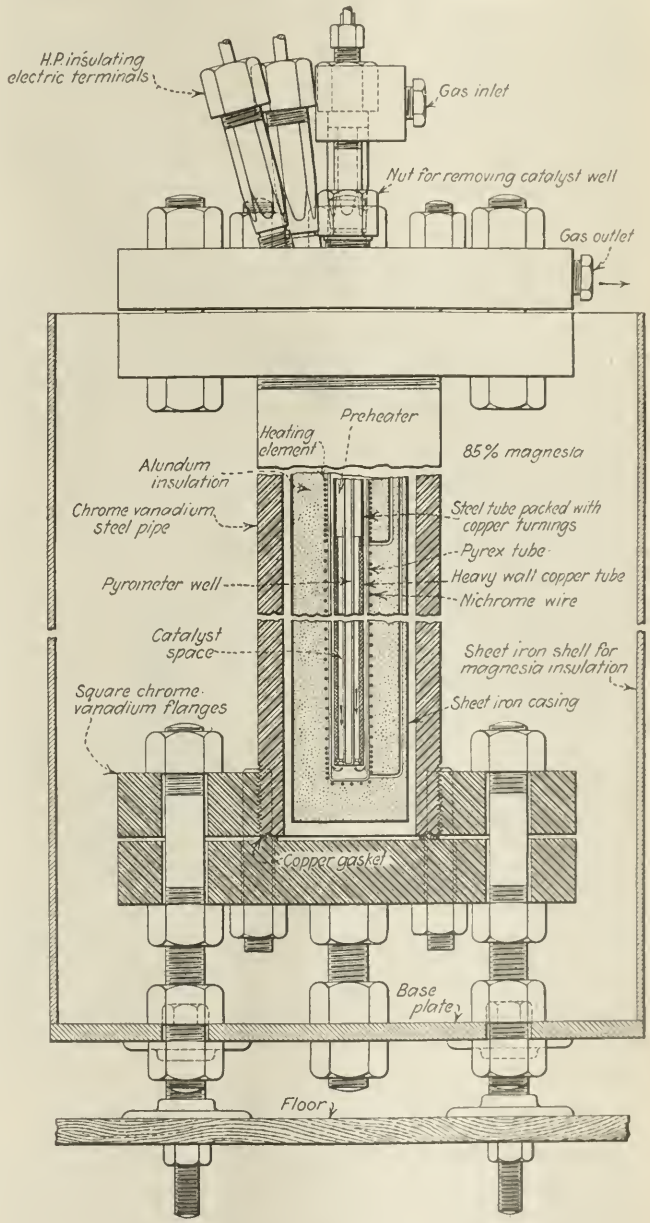

FIG. 4—CATALYST BOMB USED FOR TESTING AT 100 ATMOSPHERES PRESSURE

The design of the catalyst tube, determination of the direction of the flow of the gases and the winding and construction of the heating coil represent the results of extensive investigations whose object has been to cut down as far as possible the temperature gradient through different parts of the catalyst. Earlier designs of heating element, especially those with uniform wind-

ing and no preheater, proved on investigation to have temperature gradients as high as 200 deg. C., due partly to uneven heating and radiation and partly to localized evolution of the heat of reaction. Since the ammonia equilibrium varies rapidly with the temperature, no conclusions can be drawn as to the efficiency of a catalyst when part of its mass is 200 deg. higher in temperature than another. The method finally adopted consisted of a double winding of nichrome wire, closely wound at the top where the tube jackets the preheater, coarsely wound in the center at the location of the catalyst, and closely wound again at the bottom, where the radiation to the bottom flange of the bomb is large, has minimized this serious difficulty. Leads at top, bottom and middle are provided and with proper adjustment of resistances it becomes possible to introduce variations in the current supplied to the different portions of the tube and thus adjust the temperature as the temperature explorations in the pyrometer well may indicate. Even with widely varying rates of flow of gas it is possible with this arrangement to make the entire temperature gradient less than 10 deg. C.

Control and Measurement of Gas Flow

In the high-pressure system proper the control of gas flow is effected by the use of high-pressure valves, the design of which is given in Fig. 5. These valves are introduced between all the items of the system and are arranged to permit bypassing gas at different points in the line and also withdrawing samples for test analysis. For reduction of the pressure of the system after the gas has passed the catalyst bomb the gas passes through one of the larger high-pressure valves, then through a smaller valve[1] and finally through a section of high-pressure capillary tubing, 0.014 in. in diameter. The small valve is used for the control of the rate of gas flow. The expanded gas is measured through a calibrated friction tube flowmeter. The type of flowmeter used is a modification of the usual manometer type so much used by the Chemical Warfare Service at the American University Experiment Station.[2] The main features are that it is single reading and nonblowable. The manometer liquid is Nujol colored a deep red by a small amount of National Oil Red O.

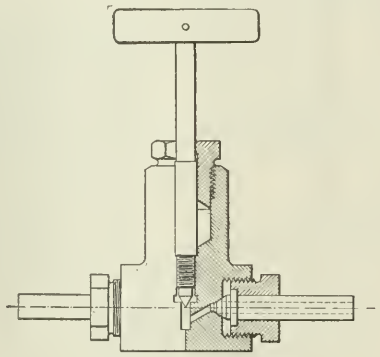

FIG. 5—STANDARD TYPE OF HIGH-PRESSURE VALVE

Control and Measurement of Pressure

Control of pressure is effected as indicated above by reduction of pressure from the high-pressure storage cylinders (3,000 to 1,800 lb.) to the desired pressure of 100 atmospheres by means of an automatic high-pressure reducing valve. The valve used is a modification of the A. W. Cash standard high-pressure piston type reducing valve. With the arrangement of storage cylinders indicated above it is possible to maintain 100 atmospheres pressure in the purification and catalyst system within 5 or 10 lb. with but occasional slight adjustment of the valve, even though the inlet pressure may vary from 3,000 to 1,800 lb. Pressure measurement is effected by Bourdon tube gages, placed on the main instrument board with the pyrometer and other measuring instruments. These gages are calibrated in place and under conditions of operation. Two Crosby recording pressure gages record continuously the pressure of the high-pressure storage and the catalyst bombs.

Control and Measurement of Temperature

Temperature control is needed in the ammonia cracker, the deoxidizers, the nickel catalyst and the catalyst chamber. Only approximate temperature control is required in the cracker and low-pressure deoxidizer, and heating there is effected by the use of a 15-kva. transformer as a source of current. The low-tension windings give a maximum of 40 volts with intermediate leads taken off to give 5-volt steps. The current through the heating elements can be thus varied by varying the impressed voltage across its terminals without the use of rheostats.

In the case of the catalyst chamber, the high-pressure deoxidizer and the nickel catalyst, this method cannot be used, because of the need of more accurate temperature control. The current used in this case is 110 volt d.c. from a 20-kw. motor generator set with a 25-kw. gasoline-driven generator for use in case of breakdown of the normal current. Plate type rheostats in series with the windings serve to control the current input and so the temperature. An ammeter and voltmeter in the circuit aid in controlling the temperature, which is finally adjusted and measured by the pyrometer.

Temperature measurement is effected in all cases by a No. 28 gage iron-constantan thermocouple, inserted into the pyrometer well. In the case of the catalyst bomb the pyrometer well extends through the entire mass of the catalyst and it is thus possible to explore the catalyst from end to end for temperature gradient.

Temperature readings are made with a Leeds & Northrup potentiometer. Two Leeds & Northrup recording potentiometers are auxiliary and maintain a continuous record of all temperatures about the plant. The couples are standardized from time to time against boiling sulphur.

Analytical Control

The ratio of ammonia formed to residual nitrogen: hydrogen constitutes the only necessary analytical determination. This is accomplished by drawing a sample of the gas through a quantity of boric acid in a bubbler to absorb the NH_3 and measuring the residual gas by a compensometer.[3] The solution is titrated with standard H_2SO_4, using bromphenol blue (tetrabromphenolsulphonephthalein) as indicator.

Introduction of Poisons Into the Gas When Desired

As previously mentioned, the two catalyst poisons removed with greatest difficulty from commercial nitrogen: hydrogen mixtures are moisture and carbon monoxide, and it is therefore desirable to study the effect of known quantities of these substances upon catalysts.

[1] See Fig. 5 in Part II of this series. CHEM. & MET. ENG., vol. 26, p. 559, 1922.

[2] See Benton, *J. Ind. Eng. Chem.*, vol. 11, p. 623 (1919).

[3] R. S. Tour, CHEM. & MET. ENG., vol. 23, No. 23, Dec. 8, 1920, p. 1104.

Moisture is introduced into the system when desired by mixing known amounts of oxygen with the nitrogen: hydrogen gas prior to compression and then passing the gas into the catalyst bomb with the deoxidizer and nickel catalyst bypassed. The oxygen reacts with the hydrogen to form water in the copper preheater of the catalyst chamber.

Carbon monoxide, prepared by passing carbon dioxide over heated carbon and then scrubbing with alkali, is introduced into the system prior to compression, the nickel catalyst being bypassed to prevent removal of CO during the operation.

Both the oxygen and the carbon monoxide are stored in a small reserve gas holder and are introduced by means of suitable flowmeters into the gas stream after it has passed the catalyst bombs and the scrubber and is on its way to the low-pressure storage.

In normal operation of the plant all readings are taken each hour and are recorded on suitable data sheets.

Conclusion

The testing plant has been used for the study of the behavior of ammonia catalysts under varying conditions of temperature, space velocity and purity of gas. These studies include consideration of the effective life of catalysts; their reproducibility; sensitiveness to and recovery from poisoning; and other factors of importance in determining the selection of a commercial catalyst.

In the fourth article of this series the results obtained with certain typical catalysts in the apparatus described in this and the preceding articles will be discussed.

World Production of Coal in 1921

The world's production of coal in 1921 dropped back to the level of 1909. From reports so far received, the United States Geological Survey estimates the total output at approximately 1,100,000,000 metric tons. This figure is subject to material revision as more complete returns are available.

In comparison with the feverish year 1920, the year just closed shows a decrease of more than 200,000,000 tons. The chief factors in the decrease were the British miners' strike, which lasted from April to June, and—more important—a world-wide industrial depression. Prices collapsed early in the year, and the seaborne coal trade of the world fell off sharply. The consequent reduction in the volume of business offered to the shipping of the world has been an important element in the decline in ocean freight rates, so keenly felt by the American merchant marine.

Of the major coal-producing nations, France and Germany were the only ones to show an increase. Progress in restoring the ruined mines of France is indicated by the steady increase in output of the past 3 years. In 1919, 22,000,000 tons was produced; in 1920, 25,000,000; in 1921, approximately 29,000,000. A further increase of 12,000,000 tons, however, would be necessary to bring French production up to the level of 1913. German production of bituminous coal is also still far below the pre-war level, although an increase was effected in 1921 as against 1920. German production of lignite in 1921 reached the highest point ever attained. The estimated output of 120,000,000 tons is an increase of 33,000,000 tons over the last year before the war.

The proportion contributed by the United States was 40.9 per cent, a larger share than in the years before the European war, but the smallest in any year since 1916.

The following table presents the information received by the Geological Survey up to Feb. 15, 1922. The tonnage of the countries not yet heard from ordinarily amounts to 12 or 15 per cent of the total. Receipt of data for these missing countries, estimates for which are included in the total, may raise or lower the final figure by some millions of tons. The unit used is the metric ton of 2,205 lb., the approximate equivalent of the long or gross ton. It is not, however, exactly the same, and the translation from net or gross tons to metric tons gives many of the figures an unfamiliar look.

PRELIMINARY ESTIMATE OF THE WORLD'S COAL PRODUCTION

(In metric tons of 2,204.622 lb.)

Country	1919	1920	1921
Australia	10,736,321	13,176,426	(*a*)

Neither 'Nor Nor 'Noxide

A product resulting from a number of processes applied to an ore is not to be classed as an ore. A decision to the foregoing effect has been handed down by the United States Court of Customs Appeals in the case of Tower & Sons versus the United States. The question arose over an importation which was assessed by the Collector of Customs as oxide of cobalt. The importer contended that it should be admitted free as "cobalt and cobalt ore." The importation was in the form of a heavy grayish black powder. It was admitted that the product was a residuum after the natural ore had been subjected to various treatments. The ore had been roasted, it was testified, to eliminate the arsenic. It then had been treated with an acid to concentrate its soluble components. A part of the residuum was precipitated, filtered, dried and ground. The court held that the product could not be classed as an ore after these treatments. Incidentally the testimony developed that it could not be classed as oxide of cobalt, since the analysis disclosed that it contained 28 per cent of oxide of nickel.

Preheating High-Speed Tools

The Bureau of Standards is testing a number of ½-in. lathe tools made of several brands of high-speed steel. One interesting point brought out in the early work is the apparent influence of preheating before hardening. Using the average of four tools, made, heat-treated and tested under the same conditions, except for preheating temperature, the results were as follows:

Preheated 20 Min. at	Hardening Heat (5 Min.)	Quenching Medium	Pounds of Metal Cut
1,400 deg. F.	2,417 deg. F.	Oil	9.1
1,500 deg. F.	2,417 deg. F.	Oil	10.1
1,600 deg. F.	2,417 deg. F.	Oil	5.1
1,600 deg. F.	2,417 deg. F.	Water	5.1

The steel in question analyzed 0.6 per cent C, 3.5 per cent Cr, 15.5 per cent W and 1.6 per cent Va.

The Control of Tuberculosis in Industries

By James A. Aupperle

THIS article covers the disease of pulmonary tuberculosis as found among the employees of our industries. A change of environment is suggested which will mitigate this disease and increase the worker's efficiency. It is an established fact that the occupation one follows has a decided effect upon pulmonary tuberculosis. In some occupations the workers are immune from this disease and in other occupations the death rate from tuberculosis is very high.

The purpose of this paper is to present the facts as we find them in the hope that tuberculosis will be mitigated by a change of environment.

It is an established fact that tuberculosis is nonexistent in certain occupations and an analysis will be made of these occupations in order to arrive at conclusions for combating this disease.

Nieszytka[1] reports that 76.5 per cent of all deaths among the sandstone workers in Hanover are due to tuberculosis. This is ten times as many deaths from tuberculosis as occur among workers in limestone. The difference is due to the fact that sandstone is siliceous and does not dissolve, while the limestone is readily dissolved by the carbonic acid present in the lungs. The particles of sandstone are sharp and irritate the tissues, which then present a fertile field for the entrance and growth of tubercle bacilli. The chances of contracting the malady are hastened by a run-down, weakened condition of the human system due to disease, vice or alcoholism.

Rotation of Work a Remedy

Many of the large trusts control so many industries that the efficiency of the tuberculous workmen can be increased by a scientific rotation of work. If an employee, on account of occupation or predisposition to pulmonary tuberculosis, can have a change of occupation, the disease will not only be arrested but the employee will get well and be of more economic value to the employer and the community.

Dampness is conductive to tuberculosis, as is evidenced by the fact that in the Philippine Islands and seacoast cities the mortality from tuberculosis is extremely high, while it is very low in dry states like Arizona, Colorado and New Mexico. The effect of dampness is counteracted by other agencies, so that if there is present a germ-destroying sulphur gas, such as hydrogen sulphide, sulphurous acid or sulphuric acid, the danger of contracting tuberculosis is reduced to a minimum. Various sulphur gases are found in coal mines, and although damp and at times dusty, the coal miner is practically immune from the disease, and those employed in coal mines have the lowest death rate from tuberculosis. Their average age at death is 51.3 years, while in all other occupations the average age at death is 47.9 years.

There is an abundance of sulphur dioxide and sulphur trioxide gases in the Pittsburgh atmosphere—in fact, there is so much that these compounds in the air cause the rusting of steel sheets to such an extent that iron sulphate forms on the metal. On the other hand, the death rate from tuberculosis in Pittsburgh is lower than any other large city in the United States. Pittsburgh is a smoky city where the large consumption of coal containing sulphur produces the germicidal sulphur gases.

Immunization by Sulphur Gases

Plaster of paris—calcium sulphate—is a combination of lime and sulphuric anhydride. This compound, when breathed into the lungs, ionizes to lime and sulphuric anhydride, the lime as bicarbonate is absorbed by the tissues and rendered harmless, while the sulphuric anhydride in the presence of water and carbon breaks up into carbonic acid gas and hydrogen sulphide gas, and is thus eliminated from the system. Calcium sulphate has such germicidal properties that in one German plaster of paris establishment there have been no cases of tuberculosis in 17 years. In another plaster of paris establishment in France tuberculosis is practically non-existent.

Selkirk[2] tells us that no workers around limekilns have died from tuberculosis. The probable reason is that coal which contains sulphur is used in limekilns and the production of germicidal sulphur gases is responsible for the non-existence of tuberculosis in this industry.

The smelter fumes in Colorado and Arizona contain large amounts of sulphur gases. In some cities the sulphur dioxide can be tasted in the air breathed. Tuberculosis is practically unknown in these districts, except in those who have contracted the disease elsewhere and who have gone to these districts to get well.

Furnace tenders are practically immune from tuberculosis, and here again we trace the beneficial effect of sulphur gases which are derived from sulphur in the coal.

In the manufacture of sulphuric acid the employees are practically immune from tuberculosis.

A sailors' and soldiers' health camp has been established at Hilo on the Island of Hawaii. It is located on the brink of one of the world's wonders, the ever-active volcano of Kilauea. The wonderful results obtained at this health resort are of world-wide renown. Tubercular patients show immediate improvement when sent to this resort. The volcano is continually giving off gas containing a large percentage of sulphur dioxide gases which is responsible for the mitigation of tuberculosis.

Large Organizations Can Help

The virtual trusts now being formed will be very useful in helping to stamp out tuberculosis. A careful survey of occupations in a large steel trust will give a good idea as to how the men with tuberculosis can be given employment where there is a possibility of curing the disease and increasing the worker's efficiency.

The following are among the jobs which should be given to men with tubercular tendencies:

Coal mining, furnace tending, cement manufacture, lime burning, manufacture of sulphuric acid, manufacture of gypsum, galvanizing where sulphur is burned, roasting of sulphide ores or wherever a small amount of sulphur gases are present from the burning of sulphur.

With the well-organized medical departments, employment and mutual interest departments, our large industries should find it an easy matter to follow the health of employees who may be given employment in departments which may mitigate tuberculosis.

Effects of Impurities on Electrolytic Zinc

Photographs of Cathodes Made in Commercial Cells After the Addition to the Electrolyte of One or Two Parts Per Million of Arsenic, Antimony, Cobalt, Copper, Nickel and Glue —Severe Action Commences Several Hours After Addition

By GUILFORD DARBY SCHOLL

THE Keokuk, Iowa, plant of the River Smelting & Refining Co. was built in 1915 and started operating in 1916, treating the zinc "fume" produced at a plant in Florence, Col., from the complex zinc-lead-copper-silver sulphides of the Colorado district when smelted by a process of roasting and reverberatory smelting.

Naturally ores of the nature treated contained impurities in varying amounts and as the Keokuk plant was entirely an experimental unit, it took several years in which to work out a successful refining process to recover the zinc as "Grade A Electrolytic." Satisfactory results were finally obtained, but not until after the close of the World War, when the zinc market had become completely demoralized.

During the 3 years of operation there were periods when production was seriously threatened by the action of impurities in the solutions. A number of tests carried out in the commercial cells were run during the closing months of operation to determine, if possible, the characteristic effects of foreign elements in the electrolyte.

Fig. 1 illustrates the arrangement of the electrodes in the cells in which the tests were made. The neutral solution entered the top cell of a cascade of four, but this flow was supplemented by an auxiliary feed into each of the three lower cells to maintain zinc concentration as constant as possible in all the cells. Fig. 1 also shows the position of the cooling coils, rubber connections and iron water and waste pipes.

In conducting the tests, the electrodes as well as the cells were thoroughly cleaned and then cut into service for an hour or two before the impurity was added. At the start sufficient "dope" solution, as it was called, was poured into the cell to give the volume of cell solution a certain predetermined content in the element under consideration. Thereafter at hourly intervals enough impurity was added to maintain this concentration. Doubtless a better plan would have been to add the impurity continuously, especially in the case of elements that deposited out with the zinc, as opposed to those that acted as catalytes.

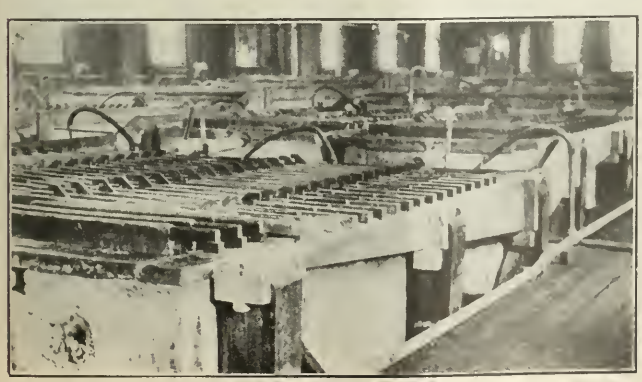

FIG. 1—CELL IN WHICH TESTS WERE MADE

The duration of a test was 48 hours—the regular stripping interval—but in numerous cases the deposit had to be stripped before this time, owing to the violent action of the impurity in redissolving the zinc faster than it was being plated. Individual cathodes, however, were removed and the zinc was stripped from time to time to obtain samples representative of the stages in the action of the impurity. From these sheets of zinc and from others taken at the end of the tests, 8-in. squares were cut and photographed. They are reproduced in this article at about one-quarter size to illustrate the effects of foreign elements upon the electrolytic deposition of zinc.

The electrolyte employed in the cells was as pure a zinc sulphate solution as it was possible to make. In fact it was a great deal purer than the so-called c.p. zinc sulphate of commerce. It ran between 70 and 80 g. per liter in zinc and varied from zero to 6 per cent in free sulphuric acid. In this article is treated only one phase of the varied and interesting experience encountered at Keokuk.

Arsenic

Sufficient arsenic solution was added to the bottom cell of a cascade to bring the content in arsenic up to one part per million. This ratio was then maintained by hourly additions. After 20 hours of deposition a cathode was removed and stripped; Fig. 2 represents the incoming solution side of the zinc deposit. Although this sheet shows nothing distinctive, yet a close examination with a magnifying glass reveals characteristics which appear more definite in succeeding photographs.

A second test followed directly upon the first and in the same cell, but the content in arsenic was increased to two parts per million. This ratio was maintained by hourly additions. After 26 hours of deposition sheet Fig. 3 was taken out. In this sheet the typical arsenic effect, as interpreted, is evidenced by the shattering of the carrot-like bamboo structure which in itself appears to indicate too much antimony in the electrolyte. Arsenic eats holes through the deposit, not only in the bottom of the recesses between the rough bamboo structure but also through the joints of this formation. The rear of arsenic-affected sheets is black around each corrosion center, with a corresponding black residue opposite on the cathode. This is in striking contrast to antimony-affected deposits.

A third test followed immediately upon the second and also in the same cell and with the same proportion of arsenic. A sheet pulled out 33 hours after the start of deposition is shown in Fig. 4. This illustrates more clearly the character of deposit yielded by arsenic. Note the similarity between this sheet and that of Fig. 3, only the effect has been intensified.

Another sheet, shown in Fig. 5, was taken out after 37 hours run and Fig. 6 shortly thereafter. Fig. 7 was

withdrawn 43 hours after the start of the test. The last three illustrate the progressive steps in the corrosion as the deposits grow older. The sheets are shot full of holes and show in a more positive degree the presence of too much arsenic in the electrolyte. Deposits of this kind naturally dross heavily in the melting furnace.

Efforts were made to detect arsine (AsH_3) in the faint sulphuric acid vapor arising from the cell, but while one trial, using a conical hood with a small vent in the top, indicated what might have been taken as a faint trace, yet it was not conclusive enough to warrant the statement that arsine is given off from a cell having arsenic as an impurity in excess of a harmless quantity.

Tests made in experimental cells by Dr. Mighill indicated that arsenic up to one part in a hundred thousand caused a serious loss in current efficiency.

Antimony

The effects of antimony are striking and distinctive. The zinc deposit is characterized by an imperfect carrot-like bamboo structure in sheets from 23 to 30 hours old and by a cauliflower-mushroom deposit in sheets 48 hours and older.

Into the bottom cell of a cascade enough antimony solution was poured to bring the content in antimony to one part per million, and thereafter enough fresh solution was added hourly to maintain this ratio.

Four hours after the first addition of antimony solution a sheet was stripped and found to weigh 179 g. per square foot, while a sheet of the same age from a regular cell weighed 237 g. per square foot. A piece of zinc from both samples was placed in the ordinary plant electrolyte and the rate of solution observed. The piece from the antimony cell dissolved just six times as fast. The surface of the antimony sheet was granular, while that of the sheet from the regular cell was smooth and of a bluish cast of color.

FIG. 8—FULL-SIZED CATHODE; POROUS AND LACY FROM RE-SOLUTION INDUCED BY ANTIMONY

Fig. 8 shows a full-sized sheet that was stripped from the test-cell. The evidence of corrosion is plainly to be seen in the characteristic antimony structure. The

Fig. 13—26¼-hr. deposit.
Fig. 14—26½-hr. deposit.

sheets were literally peppered with holes. In fact, there was very little weight left, the sheets being practically a lace-work of zinc.

After 30 hours deposition two sheets were stripped from the test-cell and the cathodes were replaced by new blanks. The zinc showed a distinct carrot-like bamboo structure on the surface and was beginning to redissolve very rapidly. At 34¾ hours the cell had to be stripped. Fig. 9 of the accompanying photographs shows this structure.

A test of the electrolyte of the cell after the zinc had been stripped revealed not the slightest indication of antimony. It would seem from this result that antimony is plated out. A test of the zinc from this cell did show antimony.

Another test was run in the top cell of a cascade in which two parts per million of antimony were added and successive hourly additions of the solution made for 48 hours to maintain this ratio. Fig. 10 shows a sheet 6¾ hours after the first addition of the "dope" solution, and Fig. 11 illustrates a sheet 11 hours old. Both reveal the action of antimony. A cathode put in the cell to replace that which yielded sheet shown in Fig. 10 was stripped 21 hours later and gave the plate represented by Fig. 12. Fig. 13 shows characteristic antimony effects. It is a sheet from the same cell, 26¼ hours old. The test run had to be discontinued before the sheets were 30 hours old, owing to the rapidity with which the sheets were dissolving. In these tests the zinc sheets were eaten away until there was only a thin backing or skeleton on the aluminum cathode, while the deposit was characterized by a growth such as is shown in Figs. 13 and 14.

A marked difference between the action of antimony

and that of any other impurity is the total absence of black spots on the cathode, even though the deposit is literally peppered with holes.

Both Figs. 15 and 16 show evidence of the presence of too much antimony in the electrolyte. These sheets were taken from the cellroom nearly a month after the two special tests described above were run. It was evident from these sheets and others, like Fig. 17, that antimony was one of the elements that had been causing frequent trouble in the cellroom for the entire period of the operation of the plant. The degree of its effect, however, varied, depending of course upon the concentration of this element. There were periods when its effect was very slight.

It is quite possible that other plants have had similar or different results from the impurity antimony. I am of the opinion, and I think all will agree, that if one element alone is present in the electrolyte or present in a predominating amount, a distinctive effect is made upon the physical character of the zinc deposit, and in most cases is recognizable. On the other hand, when two or more impurities are present and in about equal proportions, it is almost if not entirely impossible to distinguish the effects as due to this or that element.

From the experience gained at Keokuk and under the conditions of the scheme of operations employed, it can safely be concluded that the presence of antimony in the electrolyte in excess of one part in five million is decidedly objectionable. Test-cells run by Dr. Mighill in the laboratory indicated a current efficiency of only 85 to 90 per cent even at this dilution.

FIG. 24—POROUS DEPOSIT FROM A PITTED CATHODE

Cobalt

In an effort to obtain some characteristic effects of cobalt upon the deposition of zinc, enough cobalt solution was added to the bottom cell of a cascade to bring the cobalt content in the electrolyte to four parts per million, the manganese content at the same time being 0.023 per cent. The addition of the cobalt solution was made after the deposit on the cathodes was 1½ hours old and enough solution was added hourly to maintain this ratio.

Instructions were left to report immediately any unusual occurrences. Twenty-two hours later the cell was "going bad." Within half an hour the sheets were inspected, having been withdrawn from the cell in the meantime. Fig. 18 is a photograph of a sample taken

from the sheets. The surface of the deposit was characterized by a blunt fibrous structure, showing excessive corrosion. The test had not proceeded far enough, however, as the weight of zinc indicated a current efficiency of over 80 per cent. A piece of zinc from this cell placed in the ordinary electrolyte dissolved just twice as fast as a piece from an adjoining cell. Under the microscope the former showed very smooth edges, while the zinc from the ordinary commercial cell which had not been "doped" was comparatively sharp. In the light of subsequent experience this test showed that the critical period between the deposition and the action of the cobalt had been reached.

Another test was run, using the top cell of a cascade, but with only two parts per million of cobalt in an electrolyte containing 0.021 per cent manganese. This content was maintained for 48 hours. As neutral solution alone was flowing into this cell, more striking results were expected. Fig. 19 shows a sheet 34½ hours old, very badly corroded but still having considerable weight. In this sheet the fibrous structure can be recognized, although disguised by its knotty character.

FIGS. 25 TO 27—48-HR. DEPOSITS FROM SOLUTIONS CONTAINING 2 AND 5 PARTS COPPER PER MILLION

A sheet from the same cell 15½ hours old but taken from the outgoing solution side of the cathode revealed nothing of value, it being only slightly roughened.

On the other hand, Figs. 20 and 21 illustrate the character of the deposit when the cell was stripped at the end of 48 hours. The similarity to Fig. 18 is apparent, although the fibrous structure shown in Fig. 20 is sharper and the sheet shown in Fig. 21 very porous, the latter being practically a skeleton.

These tests demonstrated the extremely dangerous action of cobalt when present in the electroylte in an amount from one part per million and upward.

While Fig. 22, which represents a typical sheet of zinc from the day's production, is similar in appearance to Fig. 20, yet the fibrous character is not as sharp nor the corrosion as deep, the deposit being considerably heavier.

Another striking effect of cobalt is shown in Fig. 23, which represents a 48-hour sheet taken from the cell next below the test-cell. The corrosion here is very marked and appears to be an advanced stage of Fig. 19. However, such contrasts are not unusual and often are explained by the position of the sheet in the cell. The side of a cathode facing the inflowing solution will almost invariably show the more marked and characteristic effects of an impurity. Then, too, cobalt appears to have a more virulent effect upon the deposit in the cells next below that which has been "doped" with the impurity.

Fig. 23 tends to support the supposition that some impurities do not reach their maximum effect upon the zinc deposit until they have been in the cells for some time. It is reasonable to believe that they enter into other forms or compounds under the action of the electric current or in association with other impurities in the cell or both.

Effect of Condition of Cathode

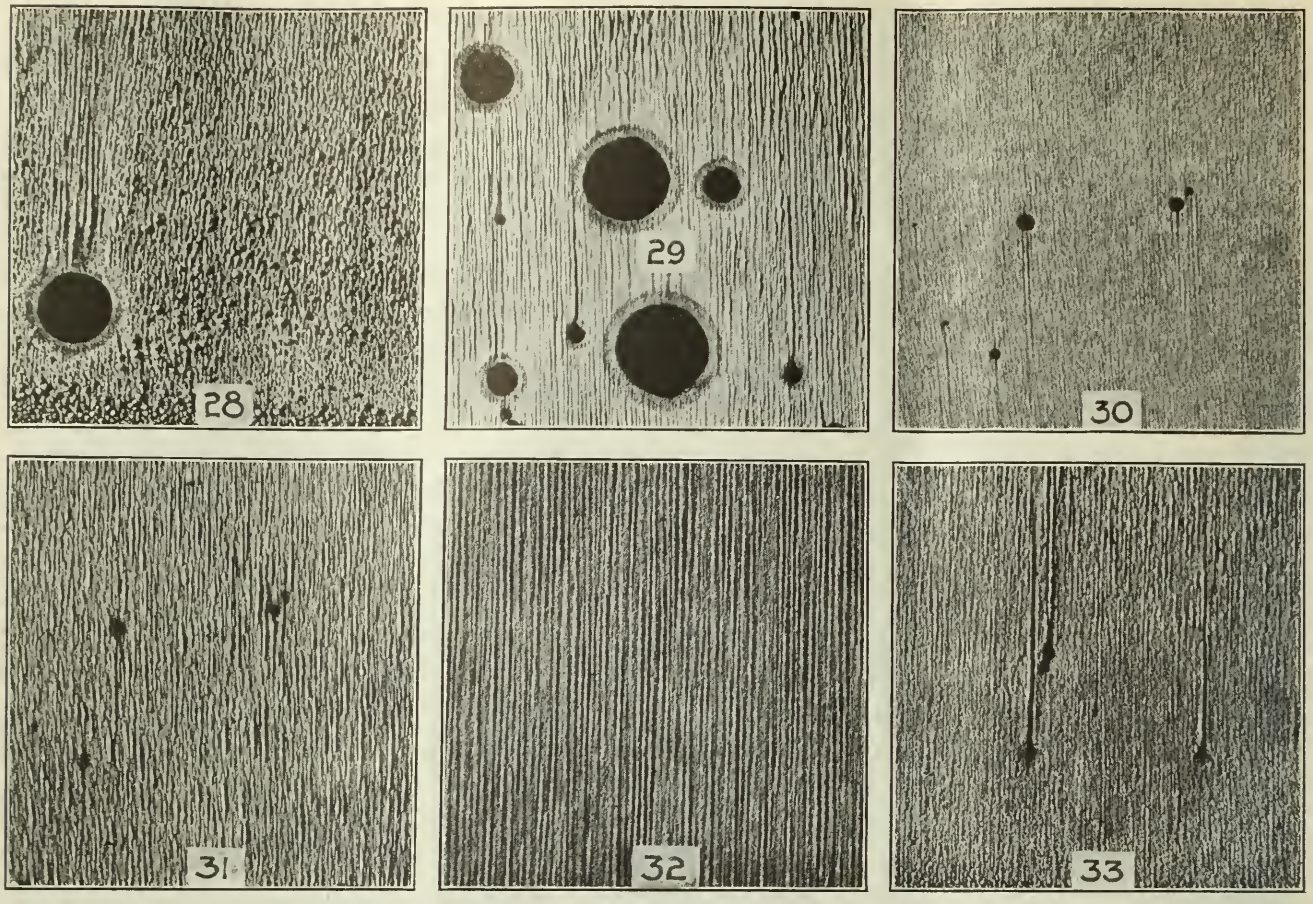
Fig. 24 shows the back of a fragment of a zinc sheet which was deposited upon a badly pitted cathode. This test was run to demonstrate that a badly corroded and pitted aluminum cathode will invariably yield a porous zinc plate, the holes in the deposit corresponding to the pits in the cathode. The test also gave supporting evidence to the idea that impurities in an electrolyte are much less active when the cathodes are clean and smooth than when they are rough and pitted. To confirm this view, 300 g. of the fragment (which, by the way, was not taken from the cobalt test cells) and 300 g. from a first-class zinc deposit of the same day were run for cobalt. The fragment showed a trace of cobalt, about one in five million, while the sample from the first-class deposit revealed no cobalt whatever.

Copper

It was known that copper was an undesirable element in the electrolyte, for whenever it rained any leaks through the cellroom roof dripping down upon the electrodes invariably streaked the deposits by washing copper sulphate from the copper conductor bars to the zinc deposit. The zinc would dissolve away wherever the copper solution came into contact with the plates, leaving the aluminum bare, but these plates would "heal" again after the dripping stopped.

To find the permissible limit of copper in the solution, cells were run using two and five parts of copper per million respectively. Apparently, however, these amounts had little effect upon the zinc deposit; the samples Figs. 25, 26 and 27 taken from the cells after 48 hours show nothing distinctive. Small test-cells gave a current efficiency as high as 92 per cent with one part per hundred thousand of copper.

The tests indicated that copper to a concentration of even five parts per hundred thousand might not be dangerous. Sufficient time was not left before the close of operations to go any further with the copper tests.



FIGS. 28 TO 33—DEPOSITS FROM SOLUTIONS CONTAINING NICKEL WITH PERHAPS COBALT AND ARSENIC

Fig. 28—Characteristic nickel rings.

Fig. 29—Characteristic nickel rings.

Fig. 30—17½-hr. deposit. Nickel 2 parts per million.

Fig. 31—32½-hr. deposit. Nickel 2 parts per million.

Fig. 32—48-hr. deposit. Nickel 2 parts per million.

Fig. 33—48-hr. deposit. Nickel 2 parts per million.

It can readily be appreciated that when the accumulation of copper sulphate which gathered on the conductor bars between stripping operations or through a period of 48 hours was washed down over the zinc deposit the strength of this solution in copper was considerably more than the limits used in the tests. Its action, therefore, while striking, was not an indication of what was to be expected from the ordinary electrolyte whose content in copper was comparatively very low.

It is consequently reasonable to conclude that the amount of copper ordinarily occurring in zinc sulphate electrolyte is not a factor of any moment in the corrosion of the zinc deposit, or, in other words, has not a serious influence upon the current efficiency.

Nickel

Effects that were later distinguished as characteristic of nickel had been noted in the cellroom deposits upon several occasions during the period of operations. In Figs. 28 and 29 the distinctive effect of nickel is shown in the "nickel ring," which is a concentric banded border surrounding a corroded area. A delicate pink color fringes the area and shades off to a dusty brown or black in the outer bands.

A special test-cell was run, adding sufficient nickel solution to make its content two parts per million of nickel. Fig. 30 shows a deposit 17½ hours old, Fig. 31 a sheet 32½ hours old and Figs. 32 and 33 sheets 48 hours old. An attempt was made to reproduce in this cell the characteristic nickel effects illustrated in Figs. 28 and 29, but without marked success. It was concluded that the concentration in nickel had not been sufficient, as tests made by Dr. Mighill in small laboratory cells showed an efficiency of 85 per cent with electrolyte "doped" with one part nickel in a hundred thousand.

It also appeared that nickel was more influenced in its action than any of the other elements by the presence of additional impurities in the electrolyte. Cobalt and arsenic effects can be detected in Figs. 30 to 33, their presence evidently retarded the usual effects of nickel.

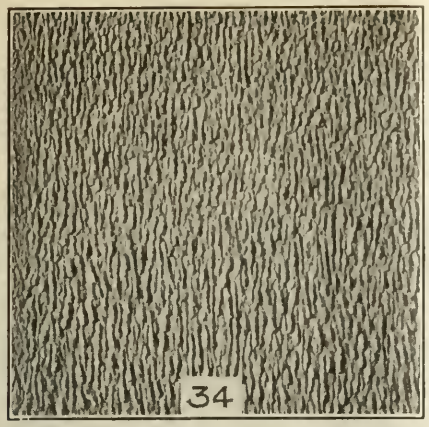
Outside of the "nickel ring" marking, electrolytes having too much nickel will produce zinc sheets that are porous and consequently light in weight.

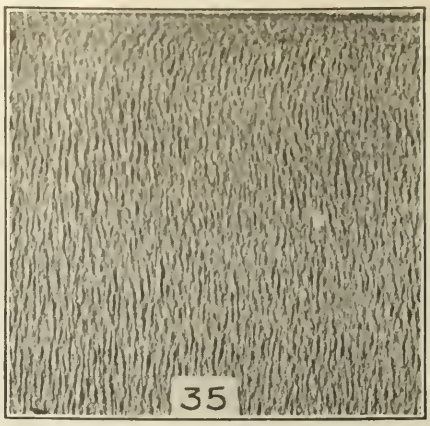
There is a similarity between the effects of cobalt and nickel in the fibrous structure, although the nickel sheets appear lighter in color and more regular in their physical characteristics.

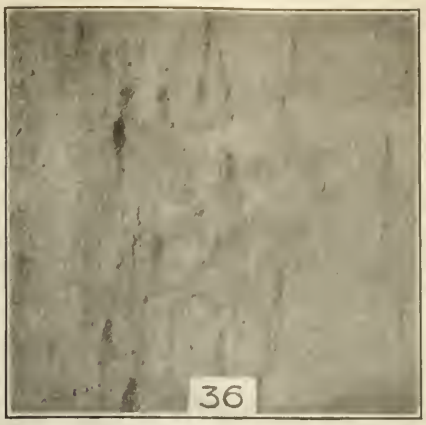
Miscellaneous Impurities

On a number of occasions the zinc deposit stuck so tenaciously to the cathodes that it was very difficult to strip the sheets. Figs. 34 and 35 illustrate sheets of zinc that were typical of deposits persisting for several days while the sheets stuck badly to the cathodes. Although Fig. 34 shows the effects of antimony, yet Fig. 35 is not distinctive but resembles more nearly a cobalt effect in its early stages. A great deal of speculation was indulged by various members of the staff upon the cause of "sticking" sheets, but no explanation actually fitted the phenomenon.

Tests conducted during the latter part of 1917 and







FIGS. 34 TO 36—MISCELLANEOUS TROUBLESOME SHEETS

Fig. 34—"Sticker"; probably affected by antimony.

Fig. 35—"Sticker"; cause unknown, possibly cobalt.

Fig. 36—Ferric hydrate working out through pores.

early in 1918 proved in a convincing manner that rough and pitted cathodes caused "sticking" of the deposit and furthermore, as noted above, that a badly pitted cathode invariably produced a porous deposit (Fig. 24). The sticking of the zinc, however, during the winter and spring of 1919 was on a more extensive and persistent scale than any previously experienced. It is quite likely that the accumulation of impurities or the presence of new impurities in the electrolyte had a contributing influence.

In this connection it should also be noted that a cathode that is too smooth will not retain a zinc deposit; it will break away as its age increases, and in some cases it actually falls into the cell or strips itself.

Colloidal Ferric Hydrate

Fig. 36 illustrates the action of re-solution, the brown streaks having been caused by gaseous action at the base of the deposit, working the "muck" out through the tiny holes in the zinc plating. In this case the "muck" was a ferric hydrate mud which had collected in the solution lines between the cellroom and the Dorr thickeners used for iron purification. It is a colloidal substance, almost non-filterable.

A number of test-cells were run to see what effect quantities of this "muck" would have upon the deposit. It was thought that it might carry the arsenic, antimony, cobalt, etc., and thus be the source of the many bad times the cellroom had experienced. However, the large cells that were doped with this muck did not reveal anything of interest. The zinc deposit was good and the current efficiency as high as in clean cells.

Glue

Whenever glue was omitted from the cells for a time, the deposit would become full of holes. This is undoubtedly due to the action of impurities which are rendered either inert or retarded in action by the glue. Fig. 37 shows a sheet that has healed after glue had been added to a cell previously free of glue. Fully half of the sheet had been dissolved away and then plated over, as evidenced by the raised patches.

The addition of glue after its total absence for some time causes a marked and almost instant change in the deposition of zinc. In one case the entire cellroom was in trouble, the sheets were peppered with holes and in some cases were actually on the verge of breaking away from the cathodes. The situation was acute, many remedies were suggested and many ideas were advanced to account for the condition, cobalt and nickel being the popular culprits. Glue was added and within 20 minutes a change had come over the entire cellroom. Re-solution had been arrested and in the great majority of cases the sheets had actually "healed" and plating had been resumed. From this and several no less striking experiments one cannot but conclude that glue has a deterrent effect upon the action of impurities.

A first-class, dense, hard crystalline deposit of zinc is shown in Fig. 38. A sheet of this character is very smooth; it is of good weight and will represent a cur-

Fig. 38—First-class cathode.

Fig. 39—Satisfactory "pebbly" deposit.

rent efficiency in the 90's. In Fig. 39 is shown the characteristic "pebbly" deposit. It is an indication of good plating and high efficiency.

Conclusion

The tests brought out the fact that impurities, as a general rule, when within reasonable limits do not attack the zinc deposit very vigorously during the first 15 or 20 hours of deposition. While it has been shown by Tarbell, for example, that the action of cobalt is catalytic, yet it appears that there is likewise either a preliminary concentration before the catalytic action starts, or the impurity is changed into another state before the corrosion begins. It is also quite possible that the effects of the impurities thrown out of solution or formed under the electrolytic action in the cell under test, or in the preceeding cells when the former is not a top cell, might easily retard or disguise the true effects of the particular impurity under investigation. The time was too limited to extend the experiments to determine these points.

It is of course evident that the phenomena noted in these tests can be variously interpreted by different investigators. In several instances, however, the evidence appeared so convincing that the conclusions drawn should be of value as a basis for further investigation.

Keokuk, Iowa.

Fullers Earth Deposit Opened in Pennsylvania

THE Furness Corporation, with main office in Chicago, has opened up a deposit of high-grade fullers earth on a 270-acre tract located at Clarksville, Mercer County, Pa. The mill, located on the Pennsylvania Railroad, is about ready to operate. Power for the mill is supplied from a plant consisting of two 150-hp. Phœnix boilers, Reed feed-water heaters and one 350-hp. Hamilton Corliss engine. Water and fire pumps operate in conjunction.

The mill plant is equipped with a Marine Iron Works disintegrating mill. Material, after passing this unit, is run through two Cummer's rotary driers. From the driers it feeds into a No. 12 Brainard hammer mill, where the first stage of pulverizing takes place.

This unit has a feed opening of 5 x 12 in. and will pulverize 5 to 8 tons per hour, of which 90 per cent will pass through a ¼-in. mesh. The hammers weigh 100 lb. each and come in contact with the earth on the upstroke. The hammer shaft has a speed of 400 to 600 r.p.m.

FULLERS EARTH MILL AT CLARKSVILLE, PA.

The material next passes into the Kneutzberg pulverizers, which operate to distribute all the coarse material in such a way as permits all the applied power to be used for actual grinding. The result is a maximum of fines with a minimum of power consumption.

Tyler whip-tap screens follow the pulverizer, and from these the finished product finally lands in the storage bins. Material is handled between units of the plant by screw conveyor equipment, all furnished by the Weller Manufacturing Co. The plant has a capacity of 60 tons per 8 hours. Installation of a dragline excavator with steam shovels at the pits is contemplated.

Some Uses of Fullers Earth

Fullers earth obtains its name from its original use in fulling cloth, extracting the greases from the wool. Its principal use now is bleaching and clarifying or filtering oils, fats and greases and is alike applied to animal, vegetable, seed and mineral oils.

It is used in the manufacture of coconut butter, oleomargarine, cold-water paint and wall paper and in detecting certain coloring matter in food products. Its use is gradually extending, it being employed as a substitute for talcum powder, as a poultice and as an antidote for alkaloid poisons.

A common practice in filtering mineral oils is to dry the earth carefully and then grind it to a suitable mesh and run it into long cylinders through which the crude, dark mineral oils percolate slowly. The result of this practice is that the oil coming out first is perfectly white and much thinner than that which follows. The oil is permitted to percolate through the earth until its color reaches a certain maximum shade.

A radically different process is followed in filtering vegetable, seed and animal oils. In this case the oil is heated in large tanks beyond the boiling point of water, from 5 to 10 per cent of its weight of fullers earth is added and the mixture is vigorously stirred and then filtered off through bag filters, or filter presses. The coloring matter remains with the earth, likewise any foreign matter which the oil may contain, the filtered oil being a pale straw color, providing, of course, the operation has been performed with sufficient care.

New uses, such as deliming hides in the manufacture of leather, may be developed and in time create a good market for the absorbing fullers earth.

Fullers earth cake from oil mills can be used in the manufacture of hand soaps, concrete waterproofing and asphalt preparations.

Fluorspar Production in 1921

The fluorspar shipped from mines in the United States in 1921, according to H. W. Davis, of the U. S. Geological Survey, amounted to approximately 35,600 short tons, valued at $708,000, a decrease of 81 per cent in quantity and of 85 per cent in value as compared with 1920. The general average selling price per ton f.o.b. cars at shipping points for all grades of fluorspar in 1921 is estimated at $19.89, which is $5.37 less than the average price in 1920. The total shipments in 1921 were the lowest recorded for any year since 1908.

The imports of fluorspar into the United States in 1921 totaled 6,229 short tons, as against 24,612 tons in 1920, a decrease of 75 per cent in quantity and of 74 per cent in total value.

Non-Flammable Mixtures of Organic Solvents for Vegetable-Oil Extraction

Experiments With Gasoline, Benzene, Carbon Tetrachloride and Trichlorethylene Indicate That Fire Hazard Can Be Eliminated More Economically by the Use of Certain Mixtures of Flammable and Non-Flammable Solvents Than by Extraction With Pure Non-Flammable Solvents

By A. F. SIEVERS and J. D. McINTYRE

IN THE commercial extraction of vegetable oils by means of organic solvents one of the chief technical considerations is the selection of a suitable solvent. Three important factors enter into such a consideration: (1) Initial cost of the solvent and the thoroughness with which it can be recovered, (2) safety from fire hazard and the relation of such hazard to the cost of plant insurance, and (3) the quality of oil obtainable by the use of the solvent. The relative importance of these three factors depends to some extent on the character of the material to be extracted and the purpose to which the extracted oil is to be put. Economy of operation is at all times of paramount importance, hence the first two factors are closely interrelated. The third factor is probably of less importance, especially when the solvent used is sufficiently pure to admit of its complete removal from the extracted oil.

It is well known that the several solvents commercially practicable for extraction purposes have a selective action on substances other than the fat in the oleaginous material, notably the pigments. In a previous paper,[1] however, the writers have shown that in the case of the solvents gasoline (high- and low-boiling fractions), benzene, carbon tetrachloride and trichlorethylene when used in connection with such materials as cotton seed, soya beans, corn germs and peanuts, there is no relation among the color of the crude extracted oil, the color of the finished oil and the refining loss. It would seem, therefore, that so far as regards the four principal solvents—gasoline or naphtha, benzene, carbon tetrachloride and trichlorethylene—the question of the selective action is of secondary importance, the main considerations being economy and safety.

Purpose of the Experiments

Of the four solvents mentioned the two chlorinated hydrocarbons are non-flammable and the other two are flammable. Three are chemical entities with definite boiling points when pure, while gasoline is a mixture of hydrocarbons with a boiling range depending on its grade and quality. It was the purpose of the experiments recorded in this paper to determine the ratio in which the non-flammable and the flammable solvents must be mixed to make the mixture safe and to what extent such mixtures will fractionate into unsafe fractions when recovery is effected by direct heat or with a current of steam.

The chlorinated hydrocarbons are much more expensive than gasoline or benzene. While the latter solvents cost about 30c. a gallon, carbon tetrachloride and trichlorethylene cost about $1.35 a gallon (1922 quotations). It is evident, therefore, that if a considerable proportion of a cheap, flammable solvent can be mixed with the more expensive but non-flammable one, and if the resulting mixture will not fractionate into unsafe fractions upon recovery, the fire hazard can be eliminated with an appreciably lower cost than if pure non-flammable solvents were used.

Preparation of Solvents

The benzene and trichlorethylene for the following experiments were used without further treatment, but the trichlorethylene was somewhat yellow and was consequently distilled over a direct flame to obtain a colorless product. The gasoline was obtained from ordinary motor fuel by means of distillation under reduced pressure. The portion boiling below 85 deg. C. under a 25-in. vacuum was retained for use in these experiments.

TABLE I—BOILING RANGE OF THE SOLVENTS—GASOLINE, BENZENE, CARBON TETRACHLORIDE, AND TRICHLORETHYLENE

Fraction c.c.	Temperature (Degrees C.) Gasoline	Benzene	Carbon Tetrachloride	Trichlorethylene
Start*	65	73	58	60
5	90	81	75	87
10	96	81.3	76	87
15	104	81.5	76.7	87.5
20	110	81.6	77	87.5
25	116	82	77	87.7
30	122	83	77.5	87.9
35	130	84	79	88
40	141	85.5	81	88.8
45	162	87	85	90
50†	...	89	90	90.5

* Reading when the vapors began to pass into the condenser.
† In the case of gasoline only a portion of the last 5 c.c. actually passed over into the condenser; the remainder condensed on the sides of the flask.

In order to determine the boiling range of the several solvents, 50 c.c. was distilled over a direct flame and the temperatures noted after the collection of every 5-c.c. fraction. The results are shown in Table I.

Method of Testing

In testing the flammability of the several mixtures it was sought to copy as nearly as possible the conditions under which explosions or fires would most likely occur in an extraction plant—namely, the discharge of a spark in an atmosphere of the vapors of the mixture. The most likely source of ignition of such vapors in a plant is probably an electric spark such as might come from a motor. For testing purposes an automobile spark plug was suspended in a 300-c.c. beaker. By means of a hot plate the beaker was kept sufficiently hot to vaporize immediately the 2 c.c. of solvent introduced. In the midst of these vapors the spark was discharged at frequent intervals. Those mixtures which did not burst into flame from the spark were considered suffi-

ciently non-flammable to make their use in an extraction plant reasonably safe.

Preparation of Solvent Mixtures

Three series of mixtures were prepared: (*A*) Carbon tetrachloride and benzene, (*B*) trichlorethylene and benzene and (*C*) carbon tetrachloride and gasoline. In each case mixtures were prepared ranging from 95 per cent of the non-flammable and 5 per cent of the flammable to 5 per cent of the non-flammable and 95 per cent of the flammable. The specific gravities of all these mixtures are tabulated in Table II.

By the method previously described these various mixtures were tested for flammability. In series *A* it was found that 30 per cent by volume is the maximum safe proportion of benzene which can be used. In series *B* only 20 per cent by volume of benzene can be used. This shows the relative extinguishing power of the trichlorethylene and carbon tetrachloride. The gasoline as used in these experiments is evidently less flammable than benzene, since 35 per cent by volume can be used with carbon tetrachloride in series *C*. The foregoing proportions are, of course, not absolute, because with the method of testing used a difference of 1 or 2 per cent in the percentage cannot readily be detected. The proportions decided upon in the three series as being safe mixtures are all well within the safety margin. It must be understood, however, that the above mixtures are considered safe when used as such, without reference to what degree of fractionation may take place when such solvent mixtures are being recovered in an extraction plant. This phase of the matter will be taken up in the subsequent paragraphs.

Direct Distillation of Solvent Mixtures

In a solvent-extraction plant the operation most likely to lead to a leakage of solvent vapors is probably that of the recovery of the solvent either from the oil or from the residue. It is of utmost importance, therefore, that such mixtures of solvents as have been described must not only be non-flammable as such but must not fractionate upon recovery to such an extent that flammable vapors will be produced at any stage of the recovery operation. The three series of mixtures selected, which will be designated as I, II and III, were submitted to distillation under various conditions to determine the extent to which such fractionation takes place. The mixtures were first distilled directly on a steam bath, 500 c.c. being used and 50 c.c. fractions collected. The temperature at the start of each fraction was noted and the specific gravity of each fraction taken to determine the proportion of the two solvents present in the mixture. The results of these distillations are given in Tables III, IV and V.

TABLE III—RESULTS OF DIRECT DISTILLATION OF 500 C.C. OF A MIXTURE OF 30 PER CENT, BY VOLUME OF BENZENE AND 70 PER CENT OF CARBON TETRACHLORIDE. (MIXTURE I.)

Fraction	Temperature (Deg. C)	Specific Gravity at 25 Deg. C.	Proportion of Components (by Volume) Benzene	Carbon Tetrachloride
1	70	1.381	28.7	71.3
2	77.5	1.379	29.0	71.0
3	78	1.379	29.0	71.0
4	79	1.377	29.3	70.7
5	81	1.376	29.4	70.6
6	81	1.374	29.7	70.3
7	81	1.372	30.0	70.0
8	81	1.368	30.6	69.4
9	80.5	1.364	31.7	68.3
10	83–84	1.345	34.0	66.0

Specific gravity of mixture before distilling, 1.372
Specific gravity of all fractions mixed, 1.373.
Time of distillation, 1 hour, 5 minutes.

The extent of the fractionation in the case of the mixture in Table III was relatively small. The final fraction, which contained the largest proportion of benzene, was carefully tested for flammability and found to be safe. It is evident, therefore, that mixture I can be safely distilled by direct heat, because at no stage of the operation are the vapors flammable.

TABLE IV—RESULTS OF DIRECT DISTILLATION OF 500 C.C. OF A MIXTURE OF 20 PER CENT, BY VOLUME, OF BENZENE AND 80 PER CENT OF TRICHLORETHYLENE. (MIXTURE II.)

Fraction	Temperature (Deg. C.)	Specific Gravity at 25 Deg. C.	Proportion of Components (by Volume) Benzene	Trichlorethylene
1	76	1.320	24	76
2	85.5	1.324	23.1	76.9
3	86	1.328	22.4	77.6
4	86.3	1.330	22.1	77.9
5	86.3	1.333	21.6	78.4
6	86.5	1.335	21.2	78.8
7	89.5	1.340	20.3	79.7
8	90	1.347	19.2	80.8
9	92.5	1.355	17.8	82.2
10*	88	1.367	15.7	84.3

Specific gravity of mixture before distilling, 1.342.
Specific gravity of all fractions mixed, 1.341.
Time of distillation, 1 hour, 12 minutes.
* About 6 c.c. remained in the flask (consisting of 93 3 per cent of trichlorethylene).

In the case of the mixture in Table IV the maximum percentage of benzene is in the first fraction, which was found on testing, however, to be non-flammable. Mixture II can therefore be distilled by direct heat with safety.

TABLE V—RESULTS OF DIRECT DISTILLATION OF 500 C.C. OF A MIXTURE OF 35 PER CENT, BY VOLUME, OF GASOLINE AND 65 PER CENT OF CARBON TETRACHLORIDE. (MIXTURE III.)

Fraction	Temperature (Deg. C.)	Specific Gravity at 25 Deg. C.	Proportion of Components (by Volume) Gasoline	Carbon Tectrachloride
1	40	1.353	26	74
2	78	1.379	23.9	76.1
3	79	1.390	22.6	77.4
4	80	1.391	22.5	77.5
5	81	1.395	22	78
6	82	1.393	22.3	77.7
7	82	1.341	28.3	71.7
8	89	1.285	34.8	65.2
9	98	.938	75.1	24.9
10*	....	.....	....	....

Specific gravity of mixture before distilling, 1.283.
* Last fraction, apparently all gasoline, remained in flask.

It is evident at once from the data of Table V that gasoline cannot be used with carbon tetrachloride without fractionating toward the end of the distillation into practically pure gasoline, which would introduce an element of danger. This is, of course, to be expected from the wide range of temperature at which the gasoline boils. A similar mixture was distilled under reduced pressure, but in this case also the last two fractions were flammable. It follows for the same reason that gasoline could not be used with trichlorethylene.

Steam Distillation of the Solvent Mixtures

Since solvent recovery in a commercial extraction plant is accomplished to a great extent by means of steam distillation, mixtures I and II were subjected to such a distillation, with the results tabulated in Table VI.

A comparison of the results in Table VI with those obtained with direct distillation reveals the fact that a slightly greater fractionation takes place in both mixtures with steam distillation. This slight difference, however, is sufficient to make mixture II unsafe when the solvent mixture is recovered with a current of steam, since the first fraction thus obtained is flammable. The final fraction in mixture I is of doubtful safety according to the test, its proportion of benzene being a trifle too high to make such a mixture entirely safe when steam is used for its recovery. For commercial operation it would be advisable to choose a mixture with a slightly lower percentage of benzene. For instance, 28 per cent by volume of benzene and 72 per cent of carbon tetrachloride would be within the limit of safety. For mixture II a proportion of 17 per cent by volume of benzene and 83 per cent of trichlorethylene should be feasible.

TABLE VI—RESULTS OF STEAM DISTILLATION OF 500 C.C. EACH OF MIXTURES I AND II

	Mixture I — 30 Per Cent Benzene and 70 Per Cent Carbon Tetrachloride, by Volume				Mixture II — 20 Per Cent Benzene and 80 Per Cent Trichlorethylene, by Volume			
Fraction	Temp., Deg. C.	Sp. gr. at 25 Deg. C.	Benzene	Carbon Tetrachloride	Temp., Deg. C.	Sp. gr. at 25 Deg. C.	Benzene	Trichlorethylene
1*	40	1.387	28	72	45	1.308	25.6	74.4
2	68.5	1.384	28.3	71.7	72	1.315	24.5	75.5
3	68.5	1.382	28.6	71.4	72	1.323	23.2	76.8
4	68.5	1.380	28.9	71.1	74	1.326	23	77
5	68.5	1.377	29.3	70.7	75.5	1.331	22	78
6	69	1.375	29.6	70.4	77	1.335	21	79
7	70	1.371	30.1	69.9	79	1.344	19.7	80.7
8	71	1.365	31	69	79	1.349	19	81
9	73	1.356	32.3	67.7	79	1.359	18	82
10†	74–105	1.318	38	62	80–105	1.367	16	84

* Fraction 1 in mixture II is flammable.
† Fraction 10 in mixture I is of doubtful safety.

Distillation of Cottonseed Extract

In commercial operations the solvents must be recovered from the extracted oil and from the residues. Since the presence of nitrogenous and albuminous materials in the solvent extract frequently causes foaming, conditions are naturally somewhat different from those obtaining when the solvents alone are being recovered, as in the foregoing experiments. Consequently, in order to simulate plant conditions cottonseed extracts were made with a mixture of benzene and carbon tetrachloride in the ratio of 30 to 70 and with a mixture of benzene and trichlorethylene in the ratio of 17 to 83, and the solvent mixtures recovered. These extracts contained approximately 20 per cent of oil besides the usual impurities extracted by organic solvents from such seed. The distillations were started by direct heat from a steam bath and when the concentration of the extract became such as to slow up the process a current of steam was admitted and the recovery of the solvent completed. The results of this experiment are recorded in Table VII.

From these results it may be concluded that the presence of extraneous matter extracted with the oil from cotton seed does not noticeably affect the extent of the fractionation and will not result in the production of flammable solvent vapors if the proper mixture is used. It is further evident, as concluded from Table VI, that in order to provide a somewhat greater margin of safety the proportion of benzene in mixture I must be reduced from 30 to 28 per cent by volume.

In connection with the use of such mixtures as have been discussed consideration must be given to the possibility of mixtures of vapors separating according to their density. If in the course of recovery or storing such mixtures quantities of vapors should escape and remain for some time in a closed room, there is a possibility that the carbon tetrachloride vapors would settle toward the floor, thus leaving an upper stratum of flammable benzene vapors. In a mixture of vapors, however, the force of diffusion and the force of gravity are operating against each other. An attempt was made to obtain some data on this point by volatilizing several hundred cubic centimeters of mixture I in a large ash can about 3 ft. high and 14 in. in diameter and carefully sealed. After 12 hours, samples of the vapors remaining uncondensed were drawn from the top and from the bottom of the can and tested. No great difference could be discovered. Three wide-mouthed liter bottles were filled with vapors from the top of the can, pure benzene vapors and ordinary air respectively. Lighted tapers were then inserted into each bottle. The bottle containing benzene was immediately filled with flame, while the two other tapers acted very much alike except that the one in the bottle containing only air burned somewhat longer. If these results are at all indicative of what would take place on a large scale it would not seem likely that a condition such as described would result in a serious fire risk.

TABLE VII—RESULTS OF DISTILLING 500 C.C. OF COTTONSEED EXTRACTS MADE WITH MIXTURES OF BENZENE AND CARBON TETRACHLORIDE AND BENZENE AND TRICHLORETHYLENE

	Proportion of Components (by Volume)			
	Mixture I — 30 Per Cent Benzene, 70 Per Cent Carbon Tetrachloride		Mixture II — 17 Per Cent Benzene, 83 Per Cent Trichlorethylene	
Fraction	Benzene	Carbon Tetrachloride	Benzene	Trichlorethylene
1	29	71	19.7	80.3
2	29	71	18.7	81.3
3*	30	70	18	82
4	30	70	17.3	82.7
5	30.1	69.9	17	83
6	30.3	69.7	16.5	83.5
7	30.7	69.3	16	84
8	31.3	68.7	15	85
9	32.6	67.4	13.7	86.3
10†	36	64	13.5	86.5

Fraction 1 of mixture II was non-flammable.
Fraction 10 of mixture I was of doubtful safety.
Fraction 10 of both mixtures was not full 50 c.c. in volume.
* Beginning with this fraction steam was admitted in distilling mixture II.
† Beginning with this fraction steam was admitted in distilling mixture I.

Economic Considerations

In estimating the approximate economy that may be effected by the use of such mixtures of solvents as have been described consideration will be limited to the two factors, fire risk and cost of solvent.

The technical objection to the chlorinated hydrocarbons—namely, that they have a tendency to

decompose slightly in the presence of steam with the formation of hydrochloric acid, which injures the equipment, will not be discussed here. As to the quality of the oils produced by the use of the several solvents under discussion, it is not believed that there is sufficient difference in their action to be a controlling factor. The cost of carbon tetrachloride and trichlorethylene fluctuates considerably, but their cost as a rule is at least four and one-half times that of benzene. Assuming that benzene costs 30c. a gallon and the carbon tetrachloride and trichlorethylene $1.35 a gallon, the comparative costs of 1,000 gal. of the several solvents and mixtures I and II would be as indicated in Table VIII.

TABLE VIII—COMPARATIVE COST OF 1,000 GAL. OF BENZENE, CARBON TETRACHLORIDE (OR TRICHLORETHYLENE), AND MIXTURES I AND II

Solvent	Cost Per Gal.	Cost Per 1,000 Gal.	Amount Saved on 1,000 Gal. as Compared With Pure Carbon Tetrachloride or Trichlorethylene
Benzene	$0.30	$300	.....
Carbon tetrachloride or trichlorethylene	1.35	1,350	.....
Mixture I: Benzene 28 per cent Carbon tetrachloride 72 per cent	1.06	1,056	$294
Mixture II: Benzene 17 per cent Trichlorethylene 83 per cent	1.16	1,161.50	$188.50

As indicated in the table, the saving on 1,000 gal. of mixture I over a similar quantity of pure carbon tetrachloride is $294, and that on 1,000 gal. of mixture II over pure trichlorethylene is $188.50. From another viewpoint it may be said that it costs the difference between $1,056 and $300, or $756 per 1,000 gal., to eliminate the fire risk by using mixture I, while by the substitution of pure carbon tetrachloride for benzene it will cost the difference between $1,350 and $300, or $1,050, to attain this end. In the same way the cost of eliminating the fire risk with mixture II amounts to $1,161.50 less $300, or $861.50. The cost of the fire hazard as reflected in insurance rates is difficult to estimate, but it should be easy to determine for each extraction plant whether such mixtures could be economically used provided there are no other objections to the employment of carbon tetrachloride or trichlorethylene as solvents.

Conclusions

The use of such flammable solvents as benzene and gasoline in the extraction of vegetable oils has the great advantage of low cost per gallon over the non-flammable solvents carbon tetrachloride, trichlorethylene and other members of the chlorinated hydrocarbons. However, even with carefully constructed equipment and all possible safeguards the fire risk is naturally considered by insurance underwriters to warrant a much higher rate of insurance on such a plant if flammable solvents are used than is otherwise the case. A mixture of the two types of solvents in such proportion that the mixture or its vapors are at all times non-flammable would reduce the original cost below that of the high-priced non-flammable solvent and at the same time eliminate the high insurance rates.

It was found by experiment that a mixture of benzene and carbon tetrachloride in the ratio of 30 to 70 per cent by volume, a mixture of benzene and trichlorethylene in the ratio of 20 to 80 per cent by volume and a mixture of gasoline and carbon tetrachloride in the ratio of 35 to 65 per cent by volume are non-flammable to the extent that their vapors cannot be exploded or set afire by an electric spark.

These mixtures when distilled by direct heat or by a current of steam fractionate to a certain extent. The mixture containing gasoline becomes entirely unsafe. The benzene mixtures fractionate much less, that containing trichlorethylene producing a flammable fraction at the start of the distillation and that containing carbon tetrachloride producing at the end a fraction which is so nearly flammable that its use would be risky.

Mixtures entirely safe when recovered by means of either steam or direct distillation from extracted oil and at the same time containing the maximum amount of the cheaper component benzene would consist of (1) benzene 28 per cent and carbon tetrachloride 72 per cent by volume, (2) benzene 17 per cent and trichlorethylene 83 per cent by volume.

The comparative cost per gallon of the three pure solvents and of mixtures I and II indicates that the use of the latter as a means of eliminating fire risk can be effected much more economically than by the use of either of the pure non-flammable solvents.

Air Lift Supplies Cold Water for Tire Manufacture

By Ralph T. Stone

THE Denman-Myers Cord Tire Co. recently constructed a plant near Warren, Ohio, for the exclusive manufacture of cord tires. The Osborn Engineering Co. of Cleveland, Ohio, was the engineer and contractor and the equipment for producing 1,000 tires per day was installed in record time. The layout involves several distinctive features, chief of which is the use of Sullivan air lifts for delivering water from the artesian wells on the property. Large quantities of water of even temperature are required. Water from these deep wells is of constant temperature, 55 deg. F., the year around. It was realized that if the well water were pumped to a storage reservoir or tank, it would become warm in summer and the greater part of the advantage of cold water would be lost. An ingenious arrangement was devised to distribute the cold water from one of the wells direct to the plant and maintain constant pressure on the mains without the use of a storage tank. Two wells about 160 ft.

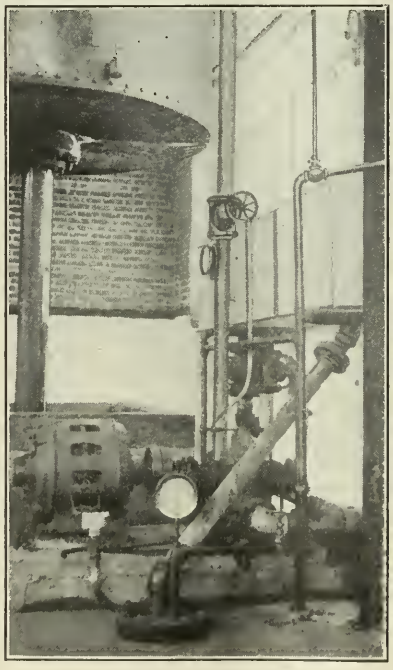

FIG. 1—VIEW IN ENGINE ROOM, SHOWING WELL NO. 1 WITH CENTRIFUGAL PUMP, COLLECTING TANK AND FLOAT-OPERATED AIR VALVE

deep and 8 in. in diameter were found to supply ample water. Well No. 1, Fig. 1, is located below the power house and Well No. 2 about 250 ft. north of the power house. Well No. 2 is equipped with a 3-in. Sullivan standard air life pump and a 24 x 24-in. booster-separator. The discharge from this well is delivered through a horizontal pipe 182 ft. long into the storage reservoir at 6 ft. elevation above the well head, as shown in Fig. 2. The booster, which is placed in the small house at the head of the well, separates the air from the water and discharges the water in a steady stream as shown.

The water from Well No. 1 is not discharged into the reservoir, but is distributed direct through the plant and furnishes a splendid supply of cold water for drinking fountains, lavatories and the mills and calenders. The low temperature of the water used in the mills and calenders greatly increases their capacity and improves the quality of the product.

Well No. 1 comes up through the floor in the engine room as shown in Fig. 1. It is equipped with a 3-in. Sullivan standard air lift pump and the water is discharged through the inclined pipe into the collector tank attached to the wall. The eduction pipe from the

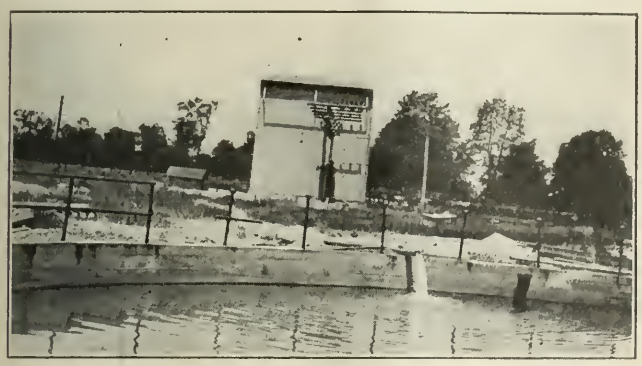

FIG. 2—DISCHARGE FROM WELL NO. 2, SHOWING RESERVOIR AND SMALL HOUSE CONTAINING BOOSTER IN THE BACKGROUND

well comes up through the bottom of the tank above the water level and is fitted with an umbrella separator to control the discharge and prevent splashing. The air line to the well passes over a corner of the collector tank and is equipped with a float-operated valve which is very sensitive in operation. This valve keeps the water at constant level in the collector tank and prevents overflowing.

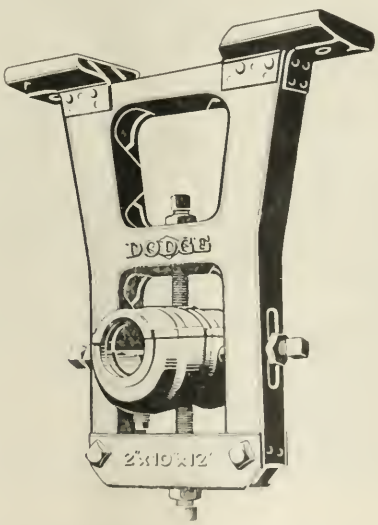
The suction of the centrifugal pump is connected to the bottom of the collector tank as shown in Fig. 1, and since it is below the water level in the tank, the pump is always primed. This pump runs continuously and maintains a constant discharge head of 90 lb. Advantage is taken of the well-known fact that a centrifugal pump maintains fairly constant pressure, independent of the quantity of water handled. The water is used all over the plant and the quantity drawn varies considerably, depending upon the number of spigots and valves which may be opened at any one time. Every valve in the distributing system may be closed at the same time without affecting conditions at the pump. In order to prevent heating of the pump when no water is being used, a ¾-in. pipe is tapped into the discharge line close to the pump and led back to the top of the collector tank as shown in the illustration. This pipe is provided with an ordinary globe valve which is kept slightly open, permitting a small stream of water to flow back into the collector tank. The apparatus has been in continuous operation since Oct. 1, 1920, and has required little attention. The plant has enjoyed an ample supply of water at all times and has been entirely free from shutdowns due to shortage of water.

Air System

Compressed air for the wells and for several manufacturing purposes is supplied by a Sullivan Class "WA-6" center crank, straight line steam-driven air compressor. This machine has a 9 x 10-in. single steam cylinder, and an 11 x 10-in. single stage air cylinder.
a capacity of 258 cu.ft. of free air per minute. The air compressor is provided with a governor which automatically slows down the machine to deliver the exact quantity of air needed. The air requirements vary and most of the time the machine is run at moderate speed.
An unloader is provided on the air cylinder which
pletely unloads the compressor when no air is being used and permits the machine to run idle with the consumption of very little steam. Adjustment is provided on the governor which makes it impossible for the compressor to stall when running at minimum speed.
The amount of air required to pump the wells, for the water supply thus far needed, is so small as to be scarcely noticeable in the load carried by the air compressor. Some of the other purposes for which the compressed air supplied by the compressor decribed above is employed include removing inner tubes from the mandrel on which they are made; holding the tires in the metal molds by means of a "bag" filled with compressed air; cleaning the molds by means of sand blasts and a gas flame under air pressure.

A New Pressed Steel Lineshaft Hanger

The accompanying illustration shows a pressed steel hanger for general purpose use, developed by the Dodge Sales & Engineering Co. of Mishawaka, Ind. This hanger is designed to meet the need for a lineshaft



hanger of lightness and strength to serve under conditions not severe or unusual and where first cost is of guiding importance. It is not believed that steel hangers are suitable for every purpose regardless of their construction, but this type seems to be quite practical under conditions which permit its use and where extreme vibration is not a factor.

Recent Chemical & Metallurgical Patents

American Patents

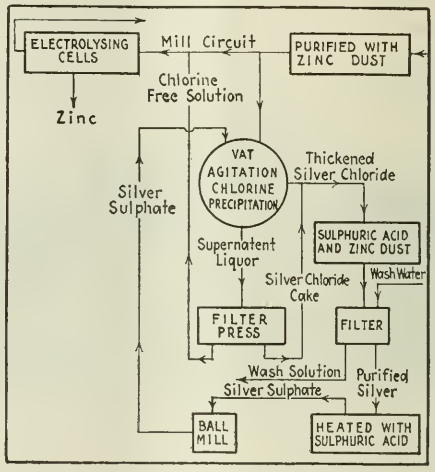
Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Anhydrous Aluminum Chloride.—The specification covers the production of aluminum chloride by suspending aluminum carbide, ground to 200 mesh, in hydrochloric acid gas and passing the mixture into a brick-lined reaction chamber wherein the application of heat brings about the reaction resulting in the formation of aluminum chloride. The reaction chamber is provided with a pair of arc electrodes which supply the heat necessary to start the reaction. The volatile anhydrous aluminum chloride passes into a series of condensers fitted with baffle plates, wherein it is deposited in powdered form. Once the operation is established, the arc is discontinued, the reaction proceeding exothermically. (1,405,183. Louis Burgess, New York, assignor to Standard Oil Co. of New Jersey. Jan. 31, 1922.)

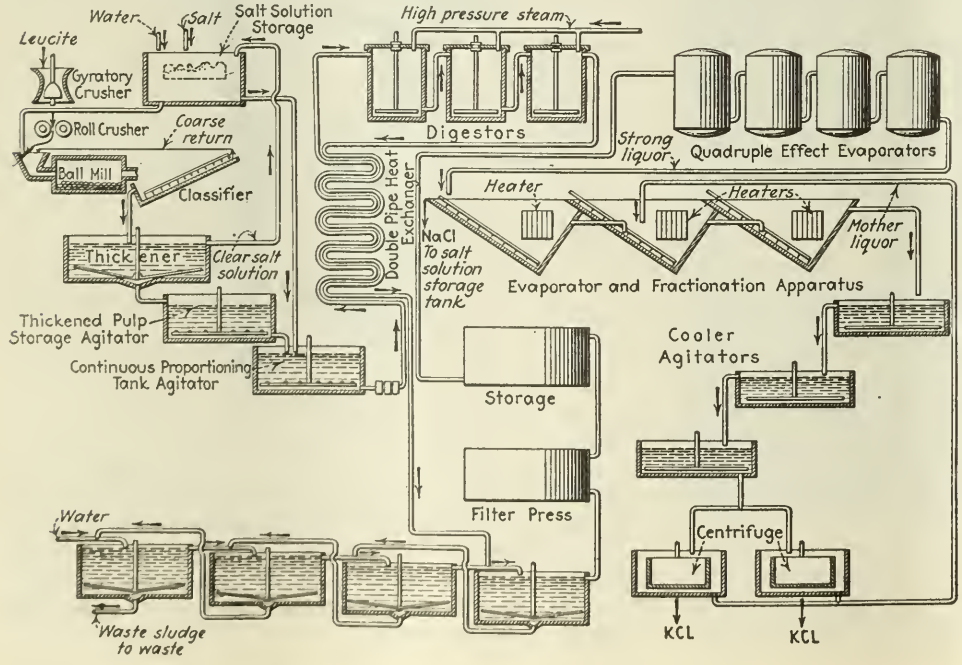
Recovery of Zinc and Copper From Brass Scrap.—Oliver C. Ralston, of Niagara Falls, N. Y., dissolves brass in chlorine water, $CuCl_2$ solution, or HCl and oxygen. If this is properly done, the zinc and copper both enter solution as chlorides. The solution, heated to 100 deg. C. is passed through a ball mill charged with a further amount of brass scrap, whereupon preferential solution occurs, the zinc passing into solution, leaving behind or reprecipitating metallic copper, and reducing soluble cupric chloride to insoluble cuprous chloride. Zinc chloride solutions resulting from this operation may be filtered, purified and electrolyzed for zinc, the chlorine also being recovered for re-use as a solvent. Cuprous chloride may also be converted into various useful salts or metallic copper. (1,402,015; assigned to Hooker Electrochemical Co. Jan. 3, 1922.)

Production of Potassium Chloride.—A continuous wet process for the recovery of potash from leucite (or a similar mineral containing a double silicate of aluminum and potassium) is based on the wet grinding of the mineral in a solution of common salt. After crushing the mineral to a suitable size and grinding it with the salt solution, the sludge is thickened and passed to a storage tank, where it is continually agitated to prevent settling. It is then passed to the proportioning tank, where salt solution is added in excess of that required to substitute the sodium for the potassium in the mineral. Thence the mixture is fed to a group of digestors subjected to high steam pressure and is raised to the temperature and pressure required for completing the chemical reaction. By fractional evaporation or otherwise the solid sodium chloride and solid potassium chloride are removed from the strong liquor, the former being returned for further use in the process, and the latter passed to a series of agitators which it traverses in series. From these coolers the crystallized KCl and mother liquor is run to a centrifuge from which the dried product is ready for shipment. The mother liquor in whole or in part is returned to the evaporating apparatus. The details of the procedure can be more easily understood if reference is made to the accompanying drawing. In this diagram no attempt is made to show the pumps which must be employed at different places in the system.

The inventor claims that 80 to 90 per cent of the potash in the mineral is replaced by the sodium providing proper conditions of concentration, temperature and pressure are maintained. (1,402,973; Mark Shoeld of Chicago, Ill, assignor to Armour Fertilizer Works. Jan. 10, 1922.)



Electrolytic Zinc.—David Avery and R. H. Stevens, of Australia, have patented a method of eliminating chlorine from zinc sulphate electrolytes, believing it the principal cause of disintegration of the lead anodes and aluminum cathodes ordinarily used in the process. (If glue is used in the process, as much as 50 mg. Cl per liter may be tolerated.) Chlorine is kept below the danger point by bleeding a certain quantity of the circulating mill solutions, after they have been purified with zinc dust. It is then made slightly acid with H_2SO_4, and finely powdered Ag_2SO_4 added to reduce (by precipitation of AgCl) the soluble chlorine to 2 or 3 mg. Cl per liter. Agitation for 1 hour is required to complete the reaction, the solution then neutralized and the precipitate coagulated by adding electrolyte. After settling, the clear solution is filtered, treated with a small amount of zinc dust, refiltered, and returned to the circuit. Methods are also outlined for the complete recovery of the silver reagent, as summarized in the diagram printed above, and consisting essentially of reduction by zinc. (1,403,065; assigned to Electrolytic Zinc Co. of Australasia Proprietary, Ltd., Jan. 10, 1922.)



Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Program of American Chemical Society Meeting Announced—Muscle Shoals Trip Canceled

With the appearance of the complete program for the spring meeting of the American Chemical Society at Birmingham, Ala., April 3 to 7 inclusive, preliminary preparations are brought to a point where an interesting session is assured. Monday, the first day of the meeting, will be devoted to a Council meeting and the Councilors' dinner at the Southern Club. Tuesday will be occupied by two general meetings and a smoker in the evening. Wednesday and Thursday will be given over to the meetings of the various divisions, all of which have arranged programs of papers except the Leather and Fertilizer Divisions. Excursions to the steel, acid, cement and other industries in the Birmingham district are planned for Friday.

The proposed side trip to Kingsport, Chattanooga and Muscle Shoals has been abandoned. The running of the special train was contingent upon 125 guaranteed fares, and since the total number of applications received up to March 20 fell short of that number, the project was dropped. As a result there will be no provision made for those attending the meeting to visit Muscle Shoals in a body.

A rate of one and one-half fare for the round trip has been granted, good from all parts of the United States except west of Utah. This reduction is contingent upon the attendance of not less than 350 members. In order to take advantage of this reduced rate, members must obtain certificates at the ticket office where the one-way ticket to Birmingham is purchased.

The general meetings will be held in the Auditorium of the Hotel Tutwiler. The divisional meetings will be held at the Hotel Tutwiler or the Southern Club unless otherwise announced. The final program is as follows:

Monday, April 3

4 p.m.—Council meeting. Southern Club.

6:30 p.m.—Dinner to the Council at the Southern Club.

Tuesday, April 4

10 a.m.—General meeting, Auditorium, Hotel Tutwiler.

Address of welcome, Nathan L. Miller, Lieutenant-Governor of Alabama.

Response, Edgar F. Smith, president, American Chemical Society.

Carlile P. Winslow, director, U. S. Forest Products Laboratory, "The Development of the Forest Products Industry in the South."

William H. Stone, associate editor, *Manufacturers Record*, "The Remarkable Development of the South and Its Relations to the American Chemical Industry."

2 p.m.—General meeting, Auditorium, Hotel Tutwiler.

Theodore Swann, "The Manufacture of Phosphoric Acid in the Electric Furnace by the Condensation and Electrical Precipitation Method."

Van H. Manning, "The Pioneer's Field in Petroleum Research."

Charles L. Reese, "Information Needs in Science and Technology."

W. C. Geer, "Recent Developments of the Chemistry of Rubber."

W. D. Bigelow, "Some Research Problems in the Canning Industry."

Francis P. Venable, "Chemistry in the Old South and the New."

8 p.m.—Smoker as guests of the Alabama Technical Association at the Southern Club.

Wednesday, April 5

9:30 a.m.—Divisional meetings, Tutwiler Hotel and Southern Club (see divisional programs).

2 p.m.—Divisional meetings continued.

8 p.m.—Public meeting, Southern Club ball room. Public address. People of Birmingham, especially ladies, invited. Marston Taylor Bogert, past president, American Chemical Society, "The Flower Fields and the Organic Chemist: Perfumes—Natural and Synthetic."

Thursday, April 6

9:30 a.m.—Divisional meetings, Tutwiler Hotel and Southern Club (see divisional programs).

2 p.m.—Divisional meetings continued.

4 p.m.—Meeting of chairmen and secretaries of local sections, Tutwiler Hotel.

7 p.m.—Banquet, Tutwiler Hotel.

Friday, April 7, and Saturday, April 8

Excursions.—There will be an excursion by special train, on Friday, to the blast furnaces, steel plants, coke ovens, mines, etc., of the Tennessee Coal & Iron Co. A barbecue dinner will be served in Southern style at 1 p.m., at Bayview Mines. The train will traverse the famous Red Mountain, which will afford an inspiring view of the industrial district.

Arrangements have also been made for individual or small party trips on Saturday to the various industrial plants in the city, such as sulphuric acid, fertilizer, slag and portland cement, cottonseed oil and filtration plants, where members may desire to go. Detailed information of this will be supplied at the registration desk. Automobiles will be furnished for this trip.

Divisional Meetings

The following divisions and sections will meet on the days noted:

Division of Agricultural and Food Chemistry, Thursday: 21 papers to be presented.

Division of Physical and Inorganic Chemistry, Wednesday and Thursday: 26 papers to be presented.

Section of Chemical Education, Wednesday and Thursday: 19 papers to be presented and a round table discussion on chemical engineering education.

Section of History of Chemistry, Thursday: 11 papers are to be presented, several of which will be supplemented by exhibits of rare books, autograph letters, documents and apparatus.

Division of Organic Chemistry, Wednesday and Thursday: 34 papers.

Division of Rubber Chemistry, Wednesday: 7 papers.

Division of Industrial and Engineering Chemistry, Wednesday and Thursday: 23 papers. This list includes 8 papers constituting a symposium on distillation.

Section of Cellulose Chemistry, Wednesday and Thursday: 18 papers.

Section of Sugar Chemistry, Wednesday and Thursday: 18 papers.

Division of Dye Chemistry, Thursday: 12 papers.

Division of Biological Chemistry, Thursday: 14 papers.

Section of Petroleum Chemistry, Wednesday: 11 papers.

Division of Water, Sewage and Sanitation, Thursday: 8 papers.

Would Shorten Term of Patent Protection

Under a bill introduced by Senator Ladd, of North Dakota, a patent would expire within 5 years after its issuance unless the patentee exercised the right to make or use the invention or discovery. In event of the assignment of the patent, the patent rights would extend only for 2 years if not worked.

Dye Monopoly Charges Begin to Look Ridiculous as Additional Testimony Refutes King Charges

Senator King of Utah, chief accuser of domestic chemical enterprises before the Senate investigating committee, very evidently is beginning to think better of the industry. That he has been embarrassed in no slight degree by the failure of his informants to justify the charges which he has voiced is very apparent. No one questions that Senator King was thoroughly convinced that all of his charges could be proved. On these fundamentals he built great superstructures, which now appear to be edifices of cards. The Utah Senator cannot hide his chagrin as one by one his charges are controverted to the seeming satisfaction of the investigating committee. Senator King's part was well done, but his mysterious informants—who were so ready to make charges—appear to be unable to substantiate any one of them. This does not mean that Senator King is convinced that the chemical industry has been conducted in an entirely flawless manner, but it is the very general impression that he has revised his opinion of the industry.

One of the outstanding developments of the week was the very convincing showing made before the committee by the Chemical Warfare Service. General Fries was not only able to refute entirely the charges which have been made against his organization, but was able to say some things about the organic chemical industry which carried more weight than if they had come from representatives of the industry.

Not the least interesting high light in the week's hearings was the testimony of H. A. Metz, who attacked the embargo from the standpoint of the importer. Mr. Metz was caustic in his comments as to the criticisms passed upon his actions by Francis P. Garvan and others, accusing him of being a German agent and insinuating that he was party to German propaganda. When Mr. Garvan interjected a remark during his account of his tariff activities, Mr. Metz flashed back, "Don't try and tell me anything about the dye business, Mr. Garvan. I've been in it 40 years and you've been in it 15 minutes."

The testimony of representatives of the manufacturers was concluded on Saturday, March 18. Joseph H. Choate, Jr., counsel for the American Dyes Institute, informed Senator Shortridge at that time that the manufacturers felt they has made their position clear and would rest their case unless it developed that the testimony of Mr. Metz made necessary the recall of some of the witnesses.

Metz Defends His Record

An extended statement in defense of his views in opposition to the embargo on dyestuffs and in reply to charges alleging a persistent effort in the interest of the German dye monopoly on his part was read into the record by Herman A. Metz of New York, importer and manufacturer of dyes and pharmaceutical products. He stated that there was no doubt that Germany had a monopoly on the organic chemical industry before the war, not because she had a monopoly on the raw materials but because of the excellence of the products. When the war broke out in 1914, Mr. Metz said, he realized the serious effect that the German embargo would have on consumers in the United States and he immediately took steps to have the embargo lifted as far as America was concerned, in order that this country might continue to receive the drugs and dyestuffs that it needed. He pointed out that he had used his best efforts to establish the manufacture of salvarsan and novocain in this country and had succeeded in producing products equal in quality to the German. "What possible basis can there be for charging me with having subserved the purposes of Germany when after 1914 I did what I always have done—assisted in the import of dyes and pharmaceuticals from the only country from which they could be obtained?" he asked.

Mr. Metz sketched the history of the importers of dyes in this country from the time when he entered the employ of an importer as office boy, 40 years ago. He touched upon his own political career and his activities as an importer and a manufacturer during the war and his litigation with the Alien Property Custodian.

The witness said that much "pure bunk" had been distributed from the Department of Commerce and other sources concerning the ability of American manufacturers to make dyes and the quality of the dyes. The trouble with the American manufacturers is that the Americans "don't know what their colors will do and the mills don't know what they want."

In reply to questions from Senator Sterling, the witness stated that he did not believe American manufacturers would ever make the high-grade dyes not made here today, because the cost would be out of proportion to the demand for them. The Germans could, he continued, because they once had the world market, but the American market is only 10 per cent of the world market.

Going into the question of salvarsan, Mr. Metz stated that the American-made product was superior to the German, but that some physicians and patients demanded the latter. Much of the German product is now being smuggled in, he told the committee. "That's the basis of my objection to the licensing system," he went on. "A man should be allowed to get what he wants if he is willing to pay for it."

Mr. Metz then went into the story of his troubles with the Alien Property Custodian. He related that Joseph H. Choate, Jr., then connected with the Alien Property Custodian, suggested that he consent to an examination of his property, the expense, to be reasonable, to be paid for by him. The Alien Property Custodian was then seeking to trace German-owned property. He agreed, but the investigation continued 5 months and the cost was $30,000. He felt that this occurrence made "highway robbery an amateur sport by comparison."

Grasselli Company Claims to Be Losing on $4,500,000 Dye Investment

The Grasselli Co. will discontinue the manufacture of dyes unless proper protection is given against foreign competition, according to statements in the testimony of William T. Cashman, vice-president of the company. The Grasselli Co. went into the dye business with much hesitation, Mr. Cashman said, knowing the difficulties ahead of it. The total invested capital of the company is $50,000,000, of which $4,500,000 is invested in the dye business. It has not put any additional capital into the business for the past year or two because of the uncertainty as to whether Congress will support the industry with protective legislation. The witness declared that keen competition exists among American dye producers, citing as examples his company's experience with Wool Green S and nigrosene.

Tariff Not Sufficient Protection

No tariff could be written to cover the American dye and organic chemical industry, testified George H. Whaley, principal owner of John Campbell & Co., New York City; the Amalgamated Dyestuffs & Chemical Works, Newark, N. J., and the Republic Color & Chemical Works, Reading, Pa. Time for research is the chief essential for development of the industry, he continued. "That time we cannot gain unless the Germans are prohibited from shipping into this country dyestuffs made here."

Emphasizes Relation of Industry to Education

Harrison E. Howe, formerly of the National Research Council, stated his belief that all chemical education and research work in the future in American universities, colleges and schools must depend upon the existence and development of a domestic dye and organic chemical industry.

"It would be futile to endow chemical education without the industry," he declared, "for the industry supports education. The industry provides opportunity for necessary research work and also provides careers for the graduate chemists of our institutions."

Dr. Howe told of the purposes of the National Research Council, which dates from the Civil War, explaining that its overhead expenses are paid from the income of a $5,000,000 endowment from the Carnegie Foundation. He said that the first suggestion of an exhibit concerning the dye and organic chemical industry came from Dr. Julius Stieglitz,

a University of Chicago professor without commercial connections with the industry. The Chemical Warfare Service obtained permission to co-operate in the exhibit as a commendable educational step. After some difficulty, he continued, the American Dyes Institute and the Chemical Foundation were persuaded to bear part of the cost. In addition, some contributions were received from individuals in the dye industry.

Value of Industry in Case of War Emergency

The testimony of Dr. Howe in regard to the exhibit was corroborated by Brigadier-General Amos A. Fries, chief of the Chemical Warfare Service, who testified that the exhibits were prepared without having in mind any special group of interests or legislation. At the beginning of the war, he said, America was without an organic chemical industry and consequently without chemical weapons. It was 11 months after the Germans began the use of poison gas before the Allies were able to retaliate but in the mean time there had been 350,000 Allied casualties from poison gas.

In answer to questions from the chairman, General Fries said that neither Francis P. Garvan, president of the Chemical Foundation, or any of its representatives ever sought to influence him to support any particular legislation, but he saw from his own experience in France the need of an organic chemical industry in this country and the need for its protection during development.

Small Manufacturers Add Voice to Denial of Monopoly Charges

Samuel Isermann, president of the Chemical Company of America and secretary-treasurer of Van Dyck & Co., of New York and New Jersey, appeared before the committee as the representative of more than forty small chemical manufacturers throughout the country. Dr. Isermann declared that the charges that had been made against the American industry were made with the idea of discrediting the entire organic chemical industry in the United States.

"We invite cross-examination by Senator King and Senator Moses," he added. "I challenge either of the Senators or anyone else to prove a monopoly exists. It simply cannot be done, and they know it. That is why they are not here. They know they cannot prove their loosely made charges by which they sought to damn this vitally important industry."

Dr. Isermann sketched briefly his own experiences as a manufacturer and his efforts on behalf of the small manufacturer to obtain legislative protection. He also read into the record extracts from a speech made on the floor of the house on July 9, 1921, by Representative Layton of Delaware, a practicing physician. Mr. Layton spoke in advocacy of the chemical schedule, pointing out the importance of the organic chemical industry in the prevention and curing of disease and for purposes of defence in time of war. Dr. Isermann also quoted from a speech made by Herman A. Metz in 1910, in which he showed very clearly that there was no organic chemical industry in the United States at that time. Practically all of the fine chemicals that were produced in this country were made by simple combination of highly refined foreign intermediates or by the purification of imported crude material.

Not the least interesting part of Dr. Isermann's testimony was his specific references to a number of cases where the German producers of fine chemicals and pharmaceuticals were able to charge outrageously high prices for their products until their patents expired or until forced down by boycotts. Ionone, for example, sold as high as $1,100 a pound in 1904, when the witness stated that he undertook the manufacture of the substance on a small scale. He was able to sell it with a profit at $75 a pound. Synthetic musk, which was introduced into the United States in 1899, sold at $1,600 per pound. As the time of expiration of the patent drew near, the price was reduced until it sold at about $20 a pound. Just before the war the price was down to $2. Numerous other specific synthetic preparations were mentioned by the witness in support of his contention that reasonable treatment could not be expected in the future at the hands of the German Cartel.

Industrial Developments of the Week

Glass. — The Wilcox-Durand Co., Newfield, N. J., has resumed operations at its local glass-manufacturing plant, following a period of curtailment. Orders on hand insure production for some time to come.

The Cape May Glass Co., Cape May, N. J., manufacturer of bottles, etc., has resumed production at its plant, following a number of weeks' shut-down. A large force of glass blowers is being employed, and certain departments are on a double shift basis.

Rubber.—The Lee Tire & Rubber Co., Conshohocken, Pa., is operating on a capacity schedule at its local plant, manufacturing about 2,000 tires a day. The new plant addition is also running on the same basis. This is the first time that maximum output at both plants has prevailed.

Oil.—The Producers' Oil & Refining Co. has resumed operations at its refinery at Gainesville, Tex., following a shut-down for about a year. The plant gives employment to about 100 men and has a capacity of 15,000 bbl. daily.

The Corona Petroleum Co. has placed its refinery at Chijol, Vera Cruz, Mexico, in commission. The plant has a daily capacity of 37,000 bbl., and is the largest in the Tampico field.

Iron and Steel.—The Carnegie Steel Co. is arranging for the blowing in of the No. 3 blast furnace at its Isabella Works, Pittsburgh district, Pa. The unit has been down since last May. The company is operating at fourteen of its fifteen furnaces in the Youngstown district, Ohio.

The Bethlehem Steel Co., Bethlehem, Pa., has resumed operations at its Saucon, Pa., plant, after an idleness of a number of weeks.

During the first week in March about 300 men were added to the working forces of the Gary, Ind., steel plants, bringing the quota to about 15,000 men in the different departments, as compared with approximately 12,000 last December. Additions will continue, it is stated, on a basis of from 200 to 300 men weekly.

The Gulf States Steel Co., Birmingham, Ala., is now operating at 100 per cent in the blast-furnace department for the first time in a number of months. The finishing mill at the plant is running on a basis of about 300 carloads during March.

The Woodward Iron Co., Birmingham, Ala., has two blast furnaces in operation at its plant, and is considering the blowing in of a third stack at an early date.

Tin Plate.—The N. & G. Taylor Co., Cumberland, Md., is arranging for the immediate resumption of operations at the bar mill and open-hearth furnaces at its local tin plant. These departments have been closed down for about a year. The mills are now giving employment to about 400 men, and this number will be increased considerably with the resumption.

Coke.—The H. C. Frick Co., Uniontown, Pa., is firing additional ovens at its local plant.

During the week ended March 9 an addition of 640 ovens was added to the active producing list at the coke plants in the Connellsville, Pa., district. Since the first of the year over 2,000 additional ovens have been placed in service.

Miscellaneous.—The Glidden Co., Cleveland, Ohio, manufacturer of paints, varnishes, etc., has adopted an overtime schedule in certain departments at the plant, about two-thirds of the working force operating until 8 o'clock each night. A full working quota is being employed at the plant. The company is operating its lithopone plant at Baltimore, Md., at full capacity, and is said to have sufficient orders on hand to insure this basis for 12 months to come.

The Solvay Co. is operating its chemical plant at Detroit, Mich., at full capacity.

The Tennessee Copper Co., Chattanooga, Tenn., will increase production in its byproduct department, primarily for a greater output of sulphuric acid for a large order received from the Standard Oil Co., to be used in connection with petroleum refining.

The Bethlehem Spark Plug Co., Bethlehem, Pa., will increase production at its plant. The company has taken an order for spark plugs for the Packard Motor Car Co., Detroit, Mich., requiring an output of about 250,000 plugs a year.

Potash Producers Ask Tariff Protection to Give American Industry a Fighting Chance

A number of points of interest in connection with the efforts of chemical industries established in America during the war to obtain adequate protection in the pending tariff legislation are brought out in the petition of forty-five American potash producers recently presented to Congress. The petition is drawn up in the form of a 43-page booklet, profusely illustrated, and presents, in popular style, a review of the development of the local potash industry under the stress of war-time needs. It also calls attention to the large amount of private capital which is tied up in potash enterprises throughout the country and which is yielding no return because the surplus of foreign potash that has been dumped on the market makes operation unprofitable.

The brief opens with a statement of the grievances of the American producers. It is pointed out that the German Government, through the Kali Syndikat, has to all intents and purposes destroyed property owned by American citizens to the extent of about $30,000,000. This attempt on the part of the German monopoly to regain its world-wide control of the potash market was predicted by German agents in 1917 when the basis of an American potash industry was being laid. It is also affirmed that German agents are now conducting an extensive propaganda in this country to mislead Congress and the public about the needs of the American potash industry to the end that it may be denied the protection it seeks from foreign aggression.

The development of local sources of potash on a commercial scale when the annual 200,000 tons which had been imported from Germany was cut off is described in the brief. The increase in production in America from 1,000 tons in 1915 to 54,000 tons in 1918 is traced, and then the decline until 1921 when the American plants were forced to shut down because of the selling at "cut rates" of enormous quantities of potash below the American cost of production. All of them are now shut down, and the carrying charges and the loss of interest are very heavy. The

POTASH WORKS OF TRONA CORPORATION AT SEARLES LAKE, CALIFORNIA

producers find now that they cannot sell a pound of potash on the American market at any price, owing to the terms of the German contracts with the fertilizer manufacturers.

The sources of supply which have been worked commercially are very widespread. Among the more promising may be mentioned the natural brines of the Nebraska lakes, Searles Lake, alunite, silicates and kelp, blast-furnace dust, molasses-distilling waste, cement-mill dust, waste from beet-sugar mills and wood ashes. Of these sources, the first are probably the most promising and represent a capital investment of over $20,000,000. At the end of 1920, the sum of $28,696,143 had been invested in the numerous plants within the United States. Some of these plants represent a cost of from $5,000,000 to $6,000,000, others a few thousands.

The American Trona Corporation, with two large plants at Searles Lake, California, is one of the principal producers of American potash. The Searles Lake deposit has been officially estimated by the U. S. Geological Survey as being sufficient to supply the potash requirements of the United States for at least 100 years to come.

Kali Syndikat Gave Warning

The brief emphasizes the deliberate and confident efforts of the Kali Syndikat to prevent the development of an American industry as follows:

"Paul Freudrichsen, whose official title is propaganda manager for the German Kali Syndikat for the Western

ANOTHER PLANT AT SEARLES LAKE

States and Hawaii, came into the offices of the Trona Corporation at different times during the 3 or 4 months immediately preceding the United States entering the World War, and stated . . . that the stockholders of the American Trona Corporation were foolish and unwise to invest their money in a potash reduction enterprise in the United States, for the reason that the German Kali Syndikat and the Imperial German Government would, after the conclusion of the war, absolutely destroy the American potash industry by marketing the German potash in the United States at such low figures as absolutely to preclude and bar any and all competition; that the German Kali Syndikat and the Imperial German Government absolutely controlled the potash production and market of the world, and pictured in great detail the immensity and strength of the German Kali Syndikat, governmentally controlled, and stated that it was useless and futile for any potash reduction enterprise in the United States to undertake to compete with the German potash, for said syndicate and the Imperial German Government intended to destroy all competition."

Threat Carried Out

"The American middlemen and fertilizer manufacturers who purchase the greater part of the potash used in this country found themselves in 1921 in an intolerable situation. The Germans manipulated the market from day to day and week to week, so that there was no stability in the business, and only one thing was certain—the German potash monopoly was underselling the American producers no matter what price was offered.

"In that situation, with some companies facing failure, owing to heavy inventories, and others fearful of making substantial purchases lest they become overstocked, the German agents approached the middlemen and fertilizer mixers with a proposition that seemed to afford some relief. In brief, they offered to sell the harassed middlemen and fertilizer companies any amount of potash at a fixed price which was very low. Then they went further, and stated they would be prepared to undersell any American producer who attempted to meet this already low figure, provided the Americans would agree to purchase all of their requirements from the Kali Syndikat during the term of the contract.

The contract was closed on Sept. 28, 1921, on the basis of the remainder of the season's supply of potash, with thirty-four American concerns dealing in potash as middlemen and fertilizer manufacturers. It provided that these concerns should purchase at the minimum 75 per cent of their requirements. It was held that it did not give the German syndicate a monopoly, since it allowed 25 per cent of the potash requirements of the trade to be supplied from other sources.

"Soon after the signing of the contract with the German Kali Syndikat, a contract similar in terms in almost every word was executed between the Société Commerciale des Potasses d'Alsace, the French potash syndicate, and the same thirty-four American potash middlemen and fertilizer companies, for 25 per cent of their seasonal requirements.

"Under these contracts, the American potash producers now find themselves completely cut off from their market, because 75 per cent of the potash used in the United States is dumped from Germany and the remaining 25 per cent is dumped from Alsace."

Pending Tariff Schedule

The American potash producers believe that the adoption of the compromise schedule which is now before the Senate will adequately protect the industry. The bill provides for a sliding scale duty on potash imports for 5 years, fixed at 50 cents per unit for 2 years, 40 cents the third year, 30 cents the fourth and 20 cents the fifth year, after which time potash will go on the free list. Domestic producers believe that this protection would assure them a reasonable price for their product and thus enable them to plan and build up quantity production. This not only would enable them to cut production costs by the development of efficient processes, but would also permit of more advantageous shipping arrangements.

The Senate Finance Committee promises to report the tariff bill by April 1. The committee has had the bill since July 21, when it was passed by the House. The unprecedented delay in handling the bill has been occasioned by an avalanche of protests against many of the rates provided in the House bill. The rates themselves would not have called out such a volume of objections, had it not been that they were coupled with American valuation, which would have the effect, many think, of increasing these rates materially. The Senate committee is keeping its own counsel. It does not confirm or deny the many rumors that are afloat as to the action it is said to have taken. It is the policy of the committee not to pass with absolute finality on any provision of the bill until it is placed on the Senate calendar.

Production Costs

The freight rate on potash from the Searles Lake region to the Atlantic seaboard is in the neighborhood of 30 cents per unit. The producers of that district believe, however, that quantity production will enable them to establish a water route through the Canal by which they will be able to lay down potash on the Atlantic seaboard at prices which can meet foreign competition.

It is also put forth that a further development of solar evaporation at the lake deposits will further reduce the cost of potash to the consumer. The present production cost has been estimated at $1.10 per unit. The German price, under the recent contract, is 64 cents. Given the protection afforded by the proposed sliding scale of duty, American producers believe that this price difference can be overcome in the 5-year period so that potash will then be put on the free list without fear of foreign competition.

Norwegian Government Considering Establishment of State-Owned Arc Process Nitrate Plants

M. Hagenmann, formerly engineer at the Norwegian Hydro-Electrical Nitrogen Co.'s works, has placed before the Ministry of Agriculture a proposal for the construction and operation of arc process nitrate plants by the government. It is calculated that niter can be sold for between 23 and 24 kroner per 100 kilos—that is, at about two-thirds of the price of Norwegian niter in December.

Claims That Tariff on Cyanide Would Menace Permanence of Gold Standard

A special plea for duty-free cyanide has been made before the Republican members of the Senate Finance Committee by Senator Oddie of Nevada. He told the committee that it is the duty of Congress to insure free cyanide to the gold producers of this country because of the bearing which the production of new gold has on the whole financial structure. He told the committee that a duty would be in the interests of a German trust and that it would discriminate in favor of German manufacturers as against American manufacturers who had located their plants just across the Canadian frontier, so as to obtain the advantages of waterpower. He also told the committee that a duty on cyanide would preclude absolutely the treatment of millions of tons of tailings. He cited the case of the Goldfield Consolidated Co. as a typical one. If cyanide is on the free list, that company will undertake the recovery of the gold content in 1,500,000 tons of tailings. The margin of profit is so narrow, however, that a duty on cyanide would put a stop to the undertaking and prevent the accretion of this new wealth.

Senator Oddie does not hesitate to criticise the attitude of the Secretary of the Treasury, which, in the opinion of the Senator, he has unconsciously taken against the gold industry. In Senator Oddie's opinion, there is only one way to insure the permanency of the gold standard, and that is to speed up the production of gold decidedly. There is a great shortage of gold in all parts of the world except the United States. Unless we turn loose our gold to meet this shortage, he says, some other standard is going to be set up. Secretary Mellon, Senator Oddie believes, is unconsciously playing into the hands of those who oppose the gold standard. His theory of no encouragement for the gold mining industry, says Senator Oddie, is as dangerous to the financial fabric of the world as are the theories of Lenine and Trotsky to its political structure. The proposal to reduce by one-half the amount of gold in gold coin is a part of this same opposition, Senator Oddie believes.

Prohibition of Oil Discharge Into Streams Issue of Moderated Pollution Bills

A new bill designed to protect shore property, fisheries and bathing from oil and acid pollution has been introduced in Congress by Representative Appleby of New Jersey. It confines the prohibition to the discharge of oil and authorizes the Secretary of Commerce to make investigation as to the effect of pollution of other discharges upon fish, reporting in 2 years with remedial legislation. Previous bills on the subject would have affected mining, coal and chemical industries by the inhibition of pollution of navigable waters.

The new bill prevents oil pollution only, including, however, oil of any kind or in any form, such as fuel oil, oil sludge or oil refuse. Except for smoothing the sea or quelling the force of waves in case of emergency and except as otherwise permitted by regulations of the Secretary of War no person or vessel would be allowed to discharge oil or permit it to run or flow into navigable waters of the United States. The Secretary of War would prescribe regulations for the use, handling and disposition of oil and for equipment of structures and vessels as will prevent oil from being discharged into such navigable waters. As punishment for violation, the offender would be subject to a fine of $2,500 or to 30 days imprisonment, or both, and denial of clearance of vessels from United States ports until the penalty was paid, and in addition revocation or suspension of license of the masters of the vessels. The penalties would not begin until 3 months after the law became effective.

The bill authorizes the Secretary of Commerce to determine what substances if any other than oils are emptied into navigable waters in such manner as to endanger or interfere with navigation, commerce or fisheries, reporting in 2 years with legislative recommendations.

Senator Frelinghuysen of New Jersey has introduced a bill identical with that introduced in the House by Representative Appleby.

Brigadier-General Fries Emphasizes Value of Chemical Warfare Service

The drastic reduction in the appropriation for the Chemical Warfare Service recently prescribed by the House Appropriations Committee has aroused a storm of protest from those who feel that necessary defensive research will be crippled by lack of funds. Although it is generally felt that the agreement of the Arms Conference definitely outlawed the production of poison gases, there is considerable doubt as to what extent a national defense program demands research in order to be on guard against the use of gas by unscrupulous enemies.

Brigadier-General Amos A. Fries, chief of the Chemical Warfare Service, has issued a statement, dated March 21, in which he points out the place filled by the Chemical Warfare Service during the war and outlines the value of such service for the future. Extracts from the statement follow:

Whether or not a service shall be separate under the General Staff depends on whether that service is fundamentally different from all other services. We have a Chemical Warfare Service to handle all general chemical problems just as every great organization today has a chemical, research, development and proving organization distinct from its engineering organizations.

The present work of the Chemical Warfare Service can be largely extended to the benefit of the army and navy. Wherever general chemical investigation or development is needed, whether research, small-scale manufacture or the proving out and testing of chemicals, the Chemical Warfare Service, with its highly trained personnel, its close contact with chemical societies, the chemical business industries and chemical research institutions, can do the work quicker and cheaper than any other agency available to the army or navy. Likewise, whenever information on any chemical subject is needed, the Chemical Warfare Service, through its contact with the above-named agencies and all governmental departments interested in chemistry, can collect the information in the form desired quicker and cheaper than any other agency.

Interpretation of Gas Treaty

The treaty concerning submarines and gases does not pretend in any way whatsoever to abolish the Chemical Warfare Service. It is simply an agreement not to use gas against each other in war. Our allies in the World War—England and France—through their representatives, particularly emphasized this point, thereby making it clear that they expected to go right ahead with full preparations in chemical warfare even to the extent, if necessary, of accumulating supplies of war gases and the shells and other containers in which to use them to meet a possible violation of the treaty by a signatory power or the refusal of some power not to sign the treaty.

Protection against gases in war can be achieved only by the mask and protective clothing. We must have these in perfect shape and ample quantities, based on chemical knowledge that is kept up to the minute. Without them a gas attack means annihilation to an army.

Question of Economy

No economy can be achieved by its combination with any other service. As before stated, chemistry is such a fundamental and far-reaching science that men must give their entire time to it if they are to achieve efficiency. That being true, there could be no efficiency in putting it under another service, because it would not decrease personnel. Indeed, under another service its cost would be greatly increased through loss of the esprit de corps of the workers and the loss of the support of the profession and industries represented in civil life by chemistry.

Functions Other Than Poison Gas Research

The Chemical Warfare Service has from the beginning handled not only research, proving, development and manufacture and supply of war gases, but the research, development, proving, manufacture, filling into containers and supply of all smoke and incendiary materials. Incendiary materials, except as incidental to smoke, are of comparatively little importance. Smoke, however, on account of its extraordinary screening properties, is of vital importance to the army and the navy.

There is one phase of the work of the Chemical Warfare Service not yet touched upon. It is, however, of vital importance. It lies in the twilight zone between the work of the medical department and pure chemistry. It is pathology, or the study of the effects of gases and other chemicals on flesh, whether fowl, beast or man. It is absolutely essential in determining whether a gas is powerful enough for use in war. This study is just as necessary for defense as it is for offense. It is a guide to what the enemy may use. It is used first to determine the toxicity of various chemical compounds, of which there are several hundred known. It becomes the final test in the field as to whether the result achieved in the laboratory can be reproduced practically in war.

Chicago Engineers Told of Research Work on Insulating Materials

Speaking before a joint meeting of the Chicago Section of the American Society of Mechanical Engineers and the Western Society of Engineers March 20, Dr. Edward R. Weidlein outlined the development of the Mellon Institute of Industrial Research. It had been expected that Dr. Weidlein might give some results of the high-temperature insulation work which the Institute is now conducting, but as this subject is to be reserved for the spring meeting of the Mechanical Engineers, consideration of this phase was limited to the general characteristics of 85 per cent magnesia insulation. The accepted figure of loss from bare pipe of 3 B.t.u. per hr. per sq.ft. per degree difference in temperature has been found to be higher as the temperature of the steam is increased and to vary with the diameter of the pipe. With insulated pipe the loss increases slightly with the temperature, but in no such ratio as for bare pipe. Enthusiastic discussion followed on insulation for underground piping, the effect of air velocity over the piping and a variety of subjects.

Memorial Fund to Stimulate Study of Chemistry Planned in Honor of Charles Baskerville

The faculty and students of the College of the City of New York have launched a drive for the collection of funds for a memorial to the late Charles Baskerville. According to present plans the memorial will take one, two or all three of the following forms:

1. The placing of a bronze tablet on the Chemistry Building, which is to be renamed Baskerville Hall.
2. The founding of a fund to provide for a medal to be called the "Charles Baskerville Prize" and to be awarded each year to the student doing the best work in chemistry.
3. The establishment of a scholarship to permit students who qualify to pursue advanced chemistry courses in other technical schools either here or abroad.

Friends of Dr. Baskerville who wish to contribute to this fund should send contributions to Prof. W. L. Prager, Department of Chemistry, College of the City of New York.

Prepares National Pure Paint Bill

Ingredients of all paints and varnishes handled in interstate commerce must be listed on the container, if legislation being drafted by Senator Ladd of North Dakota is written on the statute books. Senator Ladd was influential in obtaining the pure paint law in North Dakota. That law has been in effect for 12 years and according to Senator Ladd has proved to be a boon to the public and to paint manufacturers. He will make national legislation to the same effect one of his principal objectives. He expects to obtain the co-operation of a number of manufacturers of paints and varnishes.

Expect Tariff Bill to Be Reported This Week

While the dye schedule of the tariff bill is still subject to change, the Finance Committee of the Senate is understood to be in practical agreement on a duty of 7 cents a pound and 50 per cent ad valorem on intermediates and 7 cents a pound and 60 per cent ad valorem on finished coal-tar products. It is expected that the tariff bill will be reported to the Senate March 31.

Congressional Committees Considering Muscle Shoals Offers Visit Plants

Three days in actual inspection of the Muscle Shoals, Ala., nitrate plants will be spent by members of the Senate Committee on Agriculture and the House Committee on Military Affairs in their consideration of the various proposals to lease the property. The inspection by the legislators will be divided into a 1-day visit to the Gorgas steam plant on the Warrior River and 2 days at Nitrate Plants No. 1 and No. 2.

The official party left Washington at 10 p.m. March 25 and was scheduled to arrive at Parrish, Ala., in the morning of March 27. Members of the Senate committee who are making the trip are Senators Norris of Nebraska, Heflin of Alabama, Harrison of Mississippi, Kendrick of Wyoming, Ransdell of Louisiana, Smith of South Carolina, Caraway of Arkansas, Ladd of North Dakota and Norbeck of South Dakota. Other Senators accompanying the committee were McKellar of Tennessee, Harreld of Oklahoma, McKinley of Illinois, Stanfield of Oregon and Nicholson of Colorado. Ten members of the House Committee on Military Affairs made the trip. A number of the members of the committee were unable to go on account of other activities and the size of the delegation also was limited by the $2,000 appropriation made to cover its expenses. The House members who made the trip are Hull of Iowa, James of Michigan, Kearns of Ohio, Miller of Washington, Hill of Maryland, Wurzbach of Texas, Quin of Mississippi, Fisher of Tennessee, Wright of Georgia and Stoll of South Carolina. The first day was to be spent in visiting the Gorgas plant. March 28 and 29 were scheduled for the inspection of the nitrate plants, the party returning to Washington March 31.

Senator Lodge of Massachusetts, Senate leader, expressed a desire that the committee defer its investigation of the plants until after the vote on the naval limitation treaty, but the Senate Agricultural Committee decided that as the trip would be short the business of the Senate would not be delayed unduly by the absence of the Senators.

Chemical Industries Protest Revival of Patent Convention of 1909 With Germany

Action by the Senate, authorizing the President to revive the patent convention entered into with Germany in 1909, has raised a storm of protest. As a result it seems probable that the President will withhold the notice reviving that treaty, pending an investigation.

The 1909 patent convention with Germany provides that, in case the United States should amend its patent laws by the insertion of a working clause, this legislation would not apply to patents of German origin. The agreement is reciprocal.

There are certain American industries which are anxious to have this reciprocal safeguard, but the arrangement is regarded as being a very detrimental one to the domestic chemical industry. The situation is made the more serious by the determination of Senator Ladd of North Dakota to push his bill requiring that patents be worked within certain periods or be forfeited. Senator Ladd is convinced that there is a growing sentiment in this country for the addition of a working clause to the patent code.

The Synthetic Organic Chemical Manufacturers' Association has voiced objection to the revival of the convention before adequate provision is made by enactment of legislation that will prevent the same situation developing in the future that faced American organic chemistry prior to the war. The attitude of this association was expressed in a letter written by Charles H. Herty, its president, to Under Secretary of State Fletcher.

The American Institute of Chemical Engineers has also set forth its objections in a memorandum forwarded to Mr. Fletcher by the president of that organization, Henry Howard, of Cleveland, Ohio. In his letter of transmittal Mr. Howard declares that it would be "nothing short of a calamity if the President should cause the patent convention treaty with Germany to be reinstated." Extracts from the memorandum follow:

"It is a known fact that this treaty was conceived and engineered by certain chemical interests of Germany and these same interests in the United States because of their fear that the United States would pass a law providing for some kind of a 'working clause' in its patent system.

"The German chemical interests realized that if they were obliged to work their patents in the United States it would be the beginning of the end of their absolute monopoly in the United States of the synthetic organic chemical industry.

"The willingness of the German Government to enter into such a treaty was from Germany's point of view almost solely to prevent a possible injury to its monopoly in the United States above referred to, and clearly shows the enormous value that those in control of the German Government placed on this monopoly and the sacrifices they were prepared to make to maintain it.

"We maintain that it is improper to allow the monopoly granted by our own patent law to be used either by an American or by an alien to foster the development of a new industry in a foreign country and at the same time to make use of this patent monopoly to prevent such new industry from being developed in the United States."

Technical Societies Interested in Philadelphia Sesquicentennial

A very pronounced feeling exists in engineering circles in Washington that the proposed Engineering Congress to be held in connection with the Philadelphia Sesquicentennial should be promoted in a national and international way, and that this can be done best by the Federated American Engineering Societies. Local promotion of the Congress would be handicapped, it is believed, by the assumption that Philadelphia engineers naturally would be inclined by the incidental benefits to their city to represent such a gathering as certain to be a momentous occasion. If the arrangements were handled by the national machinery which the organizations in many branches of engineering have set up, it is believed a different impression will be created.

At a recent meeting of the Philadelphia Section of the American Chemical Society, a national meeting of the society in Philadelphia during the Sesquicentennial Exposition in 1926 was urged.

Mexican Chamber of Commerce of U. S. Formed

Announcement is made of the organization and incorporation of the Mexican Chamber of Commerce of the United States. The object of the organization is the promotion of business and economic relations between Mexico and the United States and the dissemination of general information of reciprocal interest. The directorate is composed of an equal number of citizens of the two countries. It is said that considerable preparatory work done prior to its organization enables the Chamber to offer immediate service. Offices are established in the Woolworth Building, New York City, and at 45 Bolivar St., Mexico City.

To Explore New Territory for Oil

Arrangements have been made between the Canadian Government and Chester P. Thompson, managing director for the Thompson Oil Syndicate and for the Sanctuary Oil Co., whereby these companies will explore and in the event of discovery develop the Pakow-Ski Bird Reserve for oil and natural gas. The reserve consists of 1,920 acres and is situated in southern Alberta, just north of the international boundary.

Examination Announced for Computer Cyrogenic Lab

The United States Civil Service Commission announces an open competitive examination for computer, cyrogenic laboratory, on April 26, 1922. A vacancy in the Bureau of Mines and positions requiring similar qualifications, at $1,800 to $2,500 a year, will be filled from this examination. Applicants should apply at once for Form 1312 to the Civil Service Commission, Washington, D. C.

Enlarged German Chemical Exposition Scheduled for Hamburg in June

In connection with the general meeting of the Verein Deutscher Chemiker at Hamburg, June 7 to 11, the Fachgruppe für chemischer Apparatewesen of this society will hold its third annual exhibition of chemical apparatus, products and processes. The full title "Ausstellung der Fachgruppe für chemisches Apparatewesen" is shortened to "Achema." At Achema I in Hannover, 1920, 4,000 visited the 75 exhibits, which occupied 3,770 sq.ft. of floor space. In Stuttgart, in 1921, 120 exhibitions used 10,750 sq.ft. and there were 8,100 visitors. The space available for Achema III will be approximately 25,000 sq.ft. It is planned to continue the exhibition for a week after the close of the general meeting of the Verein Deutscher Chemiker. This society is composed largely of industrial chemists, the present membership being over 6,500.

Paper Week in New York

The week of April 10 is designated as paper week in New York, meetings of all the important associations of pulp and paper manufacturers being scheduled for that week. The annual meetings of the American Pulp and Paper Association and the Technical Association of the Pulp and Paper Industries will be held at this time, headquarters to be established in the Hotel Waldorf-Astoria. Monday will be devoted to committee meetings, Tuesday and Wednesday to general meetings and sectional meetings. The majority of the sectional meetings will deal with the technical problems of the industry. The annual banquet will be held Tuesday and the election of officers on Wednesday.

Industrial Films to Be Censored by Experts

A board of censorship for technical and industrial moving pictures has been set up by the Bureau of Mines, in conjunction with the Department of Commerce. T. T. Read is the representative of the Bureau of Mines on the board and Oliver P. Hopkins represents the Department of Commerce. These two members are to select a third member, who is to be a specialist in the activity with which the picture deals. In each instance, at least two additional persons familiar with the subject of the picture are to sit with the committee in an advisory capacity. While only the pictures prepared in the Interior and Commerce Departments will be subject to the board's jurisdiction, it is believed that other departments and outside agencies preparing industrial moving pictures will seek to have films reviewed.

Personal

Edward L. Doheny, president of the Mexican Petroleum Company, New York, has started on an inspection trip of the company's properties in Mexico, accompanied by Edward L. Doheny, Jr., and a number of other officials of the company.

Charles B. Durgin has been granted a 6 months' leave of absence from the U. S. Department of Agriculture and is now doing research work for the Federal Phosphorus Co. of Anniston, Ala.

Dr. Arthur D. Hirschfelder, professor of pharmacology of the University of Minnesota, addressed a recent meeting of the Rochester Section of the American Chemical Society, on "The Chemistry of Drugs."

S. M. Kinter has been appointed manager of the research department of the Westinghouse Electric & Manufacturing Co., succeeding C. E. Skinner. He will be located in the research laboratory building near East Pittsburgh, Pa.

M. M. Marcus, general superintendent of the Rhode Island Malleable Iron Works, Hillsgrove, R. I., spoke before the Providence Engineering Society, March 14, on certified malleable iron castings, describing the modern scientific practice in their manufacture.

George A. Miller, Jr., resigned as chief metallurgist of the Frankford Arsenal, Philadelphia, March 8, after 5 years in charge of the research metallurgical laboratories, to accept a position with the Lakecrest Citrus Products Co., South Lake Weir, Marion County, Fla., as chief chemist and general manager in the manufacture of citrus byproducts, etc.

Dr. R. B. Moore, of the Bureau of Mines, delivered an address entitled "The Rare Gases: Their History, Properties and Uses," before the Chemical Society of Washington, on March 16. The address was illustrated with lantern slides.

G. M. Norman, chemical director of the Hercules Powder Co., Wilmington, Del., becomes technical director, April 1, in charge of both the chemical and engineering departments. W. C. Hunt will become assistant technical director.

L. C. Sadd, of Pittsburgh, Pa., has been elected president of the Pittsburgh Paint, Oil and Varnish Club for the ensuing year. L. C. Stuckrath has been elected vice-president and J. D. Watson treasurer. George F. Smith has been re-elected secretary for the twenty-eighth term.

C. E. Skinner, manager of the research department of the Westinghouse Electric & Manufacturing Co., has been appointed assistant director of engineering in that company. His new duties will cover research, standards and other work along these lines. He will be located in the main engineering offices at East Pittsburgh, Pa.

J. B. Wiesel, formerly in the nitro cotton division of the Wilmington, Del., office of the Hercules Powder Co., has been transferred to the Union Plant at South River, N. J., as superintendent.

Obituary

Philip Argall, mining and metallurgical engineer, of Denver, Col., died in that city on March 19, at the age of 68, after a short illness. Mr. Argall gained prominence in his profession due to his successful treatment of low-grade Cripple Creek gold ores by the process of cyanidation. He had been identified with the mining industry of the Rocky Mountains for many years, having come to the United States from Ireland in 1887. In the course of his professional life Mr. Argall proved himself a worthy pioneer in engineering and technology and a vigorous writer in defense of his ideas. He was a member of the Mining and Metallurgical Society of America, the Colorado Scientific Society, the Institute of Mining and Metallurgy (London) and the Royal Irish Academy.

Henry A. Laughlin, one of the pioneers of the iron and steel industries in the United States, died on March 11 at his home in Chestnut Hill, a suburb of Philadelphia. He was 84 years old, and retired from active business 22 years ago. Mr. Laughlin was chairman of Laughlin & Co., Ltd., until that concern was absorbed by the Jones & Laughlin Steel Co. He was a director in the last named company when he retired in 1900.

Benjamin Magnus, consulting engineer and specialist in electrolytic refining, died at Poughkeepsie, N. Y., on March 12, 1922. Mr. Magnus was born in New York on June 23, 1878, and was educated at Columbia University, where he received the degree of electrical engineer in 1900. He was superintendent for the Anaconda refineries 1900-1903, after which he was for several years in the employ of the Calumet & Hecla Co. of Michigan and the Mountain Copper Co. of California. In 1907 he went to Australia, where he remained until 1916, being successively general manager for the Electrolytic Refining & Smelting Co. and the Mt. Morgan Gold Mines. Returning to New York he engaged in consulting practice until his death. During the war he served as a Captain in the 140th Engineers. He was a member of the American Institute of Mining and Metallurgical Engineers, Mining and Metallurgical Society and the American Electrochemical Society.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Signs of Progress

At least two of the favorable factors commented on in our recent review of February's contribution to fundamental business progress have now been confirmed by the official figures of the United States Bureau of Labor Statistics. We refer to the noticeable increase in the volume of employment that occurred during February and to the distinctly upward trend in wholesale prices. In the case of the latter the pronounced rise in the value of farm products and foodstuffs has done much to correct the maladjustment in the price levels of the principal groups of commodities. The spread between manufactured products and those of agriculture has been a serious deterrent to progress. Now the gap between the products the farmer wishes to sell, such as grains and live stock, and those he wishes to buy, such as farm implements and other manufactures, is apparently being closed in from both directions.

The rapid advances in cotton, wheat, corn, oats, rye, flaxseed, cattle, hogs and sheep caused the bureau's weighted average of 116 in January to rise to 126 in February, an increase of over 8½ per cent. Metal and metal products, on the other hand, decreased approximately 1¾ per cent in February and housefurnishings one-half of 1 per cent. Furthermore, clothing, fuel and lighting, building materials, and chemicals and drugs show no change in price levels.

The general index for all commodities, which is based on a series of 327 articles, increased from 148 to 151. The index numbers for the individual groups are as follows:

INDEX NUMBERS OF WHOLESALE PRICES, BY GROUPS OF COMMODITIES (1913 = 100)

	1921, February	1922, January	1922, February
Farm products	129	116	126
Food, etc.	150	134	138
Cloths and clothing	198	183	183
Fuel and lighting	218	183	183
Metals and metal products	146	117	115
Building materials	221	202	202
Chemicals and drugs	178	159	159
Housefurnishing goods	277	214	213
Miscellaneous	180	146	150
All commodities	167	148	150

Comparing February's prices with those of a year ago, it will be seen that the general level has declined approximately 9½ per cent during this period. Metals have shown a decrease in average price, as measured by these index numbers, of 21 per cent, chemicals and drugs 10½ per cent and building materials 8½ per cent.

Changes in Employment and Wage Rates

Tabulations from representative establishments in thirteen manufacturing industries and in the bituminous coal mining show that there was a striking increase in the volume of employment during February. The figures show that in ten of these industries there were increases in the number of persons on the payroll in February as compared with January and in only four were there decreases. The largest increase, 9.3 per cent, was in the iron and steel industry, where the survey included 108 establishments. Fifty-seven paper mills reported an increase of 1.4 per cent in the number on their payrolls in February as compared with January. In thirty-seven leather plants the increase in employment was 1.8 per cent.

Wage changes in some of the chemically controlled industries are reported in the following paragraphs.

Leather.—A decrease of 12 per cent, affecting 87 per cent of the force, was reported by one tannery. About 35 per cent of the men in one establishment were reduced 10 per cent in wages, while 75 per cent of the men in another establishment had a wage rate decrease of approximately 8 per cent. An increase of 2.7 per cent in per capita earnings appeared when January and February figures were compared.

Iron and Steel.—All employees in one mill were reduced 25 per cent in wages, while in two other mills the reduction to all employees amounted to 15 per cent. A decrease in wage rates of 13 per cent was made to 65 per cent of the men in one establishment. Four establishments reported a wage reduction of 10 per cent, affecting approximately 50 per cent of the force; while in four other establishments one-half of the employees were reduced 4½ per cent in wages. A wage cut of 8 per cent, affecting 50 per cent of the force, was reported by one concern. Another concern reduced the wages of 18 per cent of the employees about 3 per cent. Increased force and amount of time worked were reported for this industry. An increase of 5.9 per cent in per capita earnings was shown when January and February payrolls were compared.

Paper Making.—In three mills a decrease of 10 per cent in wages was made, affecting the entire force in one mill, 95 per cent of the force in the second and 36 per cent of the force in the third. One-tenth of the men in one establishment were cut 6¼ per cent in wages. Business conditions remained much the same for this month and the per capita earnings show no change when compared with the past month.

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

This week	157.65
Last week	157.49
March, 1921	157
March, 1920	252
April, 1918 (high)	286
April, 1921 (low)	140

The index number again remains practically unchanged and continues at the higher level reached early in the current month. During the past week eight of twenty-five commodities included in this compilation changed in price. Prices for five of them—citric acid, ammonium sulphate, barium chloride, caustic potash and potassium carbonate—increased and three—formaldehyde, bleaching powder and linseed oil—were selling at lower prices.

Raising Output and Reducing Costs

A number of manufacturers in their efforts to reduce production costs have turned their attention to their personnel departments, where by improving industrial relations they hope to eliminate lost motion and to obtain greater efficiency from the individual workers. The policies pursued by the American Smelting and Refining Co. are illustrative of this principle. According to a recent report, a "job analysis" covering every operation was made in one of the company's larger plants so that each employee could fully understand his function in the operation, his efficiency, the purpose, limitations and the possibilities of his position, as well as the character and necessity of the work leading up to his activity. In other words, he was acquainted with the scope and meaning of every step in the production of the company's product.

Classes were formed in executive and administrative work, in foremen's general training, and in vocational instruction. The company reports that "out of this industrial training has grown a better and closer supervision by plant executives, so that the working force on each operation has been reduced to a minimum never before

reached and a much greater production per man has been obtained."

A few figures taken from operating records at some of the company's plants during 1921 will illustrate this increase in efficiency:

Plants	Operation	Tons Per Man—Per 8-Hour Day Average 1914	Tons Per Man—Per 8-Hour Day Average Oct., 1921
Durango	Crushing	31.8	52.2
Murray	Unloading	9.2	25.3
Arkansas Valley	Roasting	6.4	13.6
El Paso	Bricking	2.0	4.4

The effect of these managerial policies on labor costs is summarized in the statement:

"In 1914, repair, supply and construction labor was paid an average of $2.42 for an 8-hour day, while in November, 1920, the rate was $5.39, an increase of 123 per cent. In December, 1921, through various readjustments, the rates for repair, supply and construction labor had been reduced to $4 for an 8-hour day. This was a decrease of 25.9 per cent below the highest rate, $5.39, paid in November, 1920."

Another saving has resulted from the installation of efficient mechanical equipment in all places where it was certain that it would reduce labor-hours per ton. This has been an important factor in lowering costs due to savings both in time and material.

Twenty-Two New Chemical Companies Organized in February

According to the compilations of the *Journal of Commerce*, twenty-two companies were organized in February for the manufacture and distribution of chemicals, drugs and dyes. The indicated investments totaled $5,200,000. In January, 1922, there were thirty-two new companies, with an aggregate investment of $37,650,000.

In the month of February a year ago the total capitalization of new organizations in the drug and chemical fields reached $12,585,000. Sixty-five new companies, each with a capitalization of $50,000 or more, were also organized in February, 1922, to engage in the petroleum industry. This compares with ninety-two such companies in January. The gross capitalization of the first noted reached $100,173,000, as against $100,250,000 in the preceding month.

The following table shows the new capital in drug and chemical concerns since August, 1914:

Five months of 1914	$16,838,000	1918	$73,403,000
1915	65,565,000	1919	112,173,000
1916	99,244,000	1920	487,148,000
1917	146,160,000	1921	108,410,900

Market and Financial Notes

German Potash Prices Are Advanced.—A dispatch from Berlin on March 21 states that an increase of 21 per cent in the market prices of potash salts had been granted the Kali Syndikat by the Imperial Potash Council. The producers, who submitted their petition to the government on March 15, declared that the higher prices were necessary because of further increases in the wages paid in the mines and to a recent advance in the freight rates on potash salts.

American Linseed Co.—The 1921 report of this company showed an operating loss of $1,043,132, as compared with a profit of $6,238,597 for the 15 months ended Dec. 31, 1920.

U. S. Cast Iron Pipe & Foundry Co.—This company had a net profit of $100,841 for the year ended Dec. 31, 1921, according to its recent report. Approximately $432,000 was charged off for depreciation.

Mathieson Alkali Shows Deficit.—The Mathieson Alkali Works, Inc., reported a net loss of $149,635 in 1921, as compared with a net profit of $524,874 in 1920. The profit and loss surplus on Dec. 31, 1921, was $1,479,932 and on the corresponding date in 1920, $1,684,347.

Freeport Sulphur Co. and the Texas Co. Agreement.—In the annual report of the Freeport Texas Co. for the year 1921, President E. P. Swenson states that the subsidiary, the Freeport Sulphur Co., has entered into a contract with the Texas Co. for taking over the latter's sulphur deposits in Hoskins Mound, Brazoria County, Texas. It is understood that the arrangement is on a contingent royalty basis.

The New York Market

NEW YORK, March 27, 1922.

The chemical market during the past week showed pronounced signs of expansion and business in the aggregate was much better, although there still remain some traces of small-scale operations. There have been instances of both shading and advancing prices on various commodities according to the demand. In the first-hand market March sales have probably not been quite up to the standard established during February. This condition is accounted for by the fact that for a number of reasons the large consumers greatly increased their February allotments. The resale market, however, has not had any setback so far this month and in many cases jobbers have completely withdrawn from trading circles in order to await higher prices.

General Chemicals

Caustic Potash.—Supplies of spot material have noticeably diminished on the 88-92 per cent imported grade, with buyers showing a little more interest in covering requirements. Small sales were reported at 6c. per pound early in the week, but later quotations were around 6¼c. Stronger conditions in this commodity abroad have also had a better influence on spot values.

Carbonate of Potash.—A reduction in offerings and an improved demand are directly responsible for the sharp advance in this commodity. The 80-85 per cent calcined was advanced to 4½c. per pound.

Bleaching Powder. — Prices on domestic material are a trifle lower. Leading sellers offer large drums at $1.70 per 100 lb., f.o.b. works, and report sales at this figure. The range is up to 2c. per pound. Imported goods are quoted at $1.85 per 100 lb. The demand has slackened off considerably.

Barium Chloride.—Prices have advanced sharply and the market is in a very firm condition. Goods afloat sold at $75 per ton. Spot material was held at $80@$85 per ton according to seller and quality. The demand was very brisk.

Caustic Soda.—Dealers report March material exceedingly firm for export and quote prices around $3.70 per 100 lb. Some sellers have booked goods far into June and state that their output for earlier months is entirely sold. Producers have not altered quotations and ask 2½c. per pound, basis 60 per cent, f.o.b. works, in carload lots.

Citric Acid.—The market showed a much firmer tendency and while the demand as yet is not especially active, spot prices have been pushed ahead by prominent sellers of imported goods. The closing price on spot was 46c. per pound. Shipments were quoted at 45c., c.i.f.

Formaldehyde.—Some manufacturers have reduced prices to 8½c. per pound, f.o.b. works, with the general quotation at 8½@9½c. per pound, depending on quantity. Competition is responsible for the present low price, which is recorded as the lowest since July, 1915.

Prussiate of Soda.—The consuming demand has fallen off considerably and the change in the market has resulted in a decided reduction in quotations. Prices as low as 17¼c. per pound were heard with the range from 17¼@17½c.

Oxalic Acid.—Continuous competition among first hands has resulted in lower prices on spot and at the works. The best price heard was 11½c. per pound. The general quotation was from 11½@12½c. per pound, depending on quantity and brand.

Sal Ammoniac.—Shipments of this material from abroad are much firmer and the market is quoted at 6¾c. per pound, c.i.f. New York. Spot prices are higher with sellers asking 7¼c. per pound for the white and gray goods.

Sulphate of Ammonia.—This material continues to be in extremely limited supply and the few who can offer goods for immediate shipment are asking 3½c. per pound.

Sulphide of Soda.—There has been a decided improvement in this material, with several sellers refusing to shade 4½c. per pound, for the fused 60-62 per cent on spot. Goods afloat were quoted at 4¼@4¼c. per pound. Domestic material was held firm at 5¼c. per pound.

Coal-Tar Products

Benzene.—Producers of this material have found a ready market since the beginning of the year and prices have been

firmly maintained on both grades. Spot goods are exceedingly scarce and regular contract shipments are still uncertain for any definite deliveries. The 90 per cent is quoted at 27@32c. per gallon and the pure water white is being held at 29@35c. per gallon. Resale material on spot is nominal at 40c. per gallon for the 90 per cent.

Solvent Naphtha.—Sales of crude are reported by producers on the basis of 22c. per gallon, while small lots have brought as high as 27c. Pure water white is moving on contract at 25@28c. per gallon. Crude heavy is held at 10@14c. per gallon.

Anthracene.—Producers report a fair inquiry for the different grades and are booking shipments at 75c. per pound for the 80-85 per cent test and at 15c. per pound for the 40-45 per cent. The low-grade 20-25 per cent material is moving on the basis of 11c. per pound.

The Chicago Market

CHICAGO, ILL., March 23, 1922.

Better conditions were to be noted in the industrial chemical market during the past week. Buyers, while still inclined to shop around considerably before placing an order, are taking on supplies in a somewhat larger volume. Prices with a few exceptions are very firm and spot stocks are only moderate. It is evident that the tendency of the market is toward higher prices, but no radical revision upward is expected in any quarter.

General Chemicals

Caustic soda, while firm, lacks quotable change, and supplies are reported to be only moderate. Solid 76 per cent is priced at $3.75 per 100 lb. and the ground at $4.50. *Caustic potash* continues in a very firm position, with small supplies offered at 6½c. per lb. delivered. *Soda ash* is moving in a routine way at $2.30 per 100 lb. for 58 per cent material in cooperage.

Alum is showing a slightly firmer tendency and is quoted at 5@6c. per lb. for lumps and 6@6½c. for powdered. *Bleach* is in fair demand and can be had in single drum lots at 3c. per lb. *White arsenic* continues firm, with small parcels quoted at 8½@9c. per lb. *Copper sulphate* is said to be moving fairly well, with $5.90 per 100 lb. the best figure noted for small lots. *Copperas* is in some demand and is available in single-barrel lots at $1.75 per 100 lb. *Carbon bisulphide* is unchanged at 6¾@7c. per lb. in single-drum lots. *Carbon tetrachloride* is in somewhat better demand at 10½@11c. per lb. *Formaldehyde* is said to be moving well, but due to the unstable condition of the methanol market the price is easy at 9½@10c. per lb. *Glycerine* is showing no improvement and c.p. material in drums is quoted by refiners at 16c. per lb.

The *bichromates* are in routine demand and lack quotable change at 11¾c. per lb. for the potash and 9@9½c. for the sodium. *Potassium permanganate* is steady at 17c. per lb. for the U.S.P. crystals and is reported to be moving fairly well in small parcels. There are as yet no supplies of *red prussiate of potash* on the market and as far as could be determined nothing for near future delivery. *Yellow prussiate of potash* is very firm, with only moderate supplies available at 28@30c. per lb. *Sodium bicarbonate* continues to move in the regular consuming channels at $2.30@$2.40 per 100 lb. *Sodium fluoride* has shown a better demand of late and is moving fairly well at 10½@11c. per lb. *Hyposulphite of soda* is being bought by the photographic trade in a better volume and pea crystals are quoted by manufacturers at $3.25 per 100 lb. for barrels.

Linseed Oil

Linseed oil was reported by a prominent factor to be moving in a very satisfactory volume. For the past week the tendency on this material has been down, but this has had little effect on the movement. Boiled oil was quoted today at 84c. per gal. in 5-drum lots and the raw oil in similar quantities at 82c.

Naval Stores

Turpentine is enjoying a very good demand and the market is firm. Today's price for 5-drum lots was 87c. per gal. *Rosin* is moving freely and with supplies heavy the competition is very keen. The WG grade was quoted today in carlots at $6.85 per 280 lb.

The Iron and Steel Market

PITTSBURGH, March 24, 1922.

The disparity in views in different quarters as to the nearby future of the steel market is much more pronounced. The divergence of opinion is so wide that a clarification within a few weeks is practically certain. In some quarters it is predicted positively that demand for steel will continue to increase in marked fashion, say to the extent that by June 1 production will be at 25 per cent greater rate than at present. In other quarters it is asserted that the call upon the mills for steel lately has been greatly in excess of the consumption, it being insisted that if the country were consuming steel at the producing rate the general appearance of industry would be quite different from that actually presented.

Those who maintain that demand will continue to increase argue that the material recently bought has been urgently needed or the buyers would not have insisted upon quick shipment as they did, that the season of the year promises an increase in consumption and that the railroads are buying more and more freely.

Those who maintain that the demand is already above a natural relation with the state of business generally suggest that buyers have simply been partly restoring their extremely depleted stocks, and probably have anticipated some of their requirements, in fear that the coal strike April 1 would interfere with production and shipments of steel.

A few weeks will stop this debate, for one party or the other will be forced to see its error. The respective sets of premises on which they argue cannot stand side by side for any length of time.

Production of steel ingots is running along at between 29,000,000 and 30,000,000 tons a year, showing but a slight increase in the past 3 or 4 weeks. Some companies are preparing to increase operations, however.

Prices

Whatever may be theory, as to commodities being marked for intermittent price declines for several years, or as to steel prices being below cost of production, the plain market fact is that in no branch of the finished steel market has there been any decline for 2 or 3 weeks past, while in some respects there has been a stiffening. The price decline may be resumed any number of times in the future, but the present fact is that the long decline, which really dates back to the latter part of 1920, stopped a fortnight or more ago. Bars, shapes and plates are firm at a minimum of 1.40c., and some business has been booked in the past few days at 1.45c. and 1.50c. while recently there was not a little business done at well under 1.40c. Several mills have formally announced that a 1.50c. minimum is their objective. Nails have been quite steady at $2.40 in recent weeks, while formerly this price was shaded somewhat. In sheets it looks as if there might be an advance from the prices ruling for over 3 months, but only after customers were given an opportunity to place orders at current prices. One independent mill has announced an advance of $3 a ton, from 3c. for black, 4c. for galvanized and 4.35c. for automobile sheets, to become effective April 1. In pipe the shading does not seem to be any greater than in the past.

By fairly heavy absorption of spot and prompt furnace coke last week the price of $3.25 has disappeared in the Connellsville trade, leaving $3.50 as the market, but demand has been light this week and additional ovens are going in. Foundry coke remains at $4.25@$4.75. Demand for Connellsville coal has become light and prices are lower. A decline in the market for Pittsburgh (union-mined) coal is also seen. There is no diminution in the prospect as to the suspension at the union mines April 1, and the market development therefore indicates that consumers generally were forehanded in laying in stocks, so as to avoid a possible rush in the last 2 or 3 weeks of March. Accordingly there is the reverse of a rush.

Pig iron remains quotable at $19.50 for bessemer, $18 for basic and $19 for foundry, f.o.b. valley furnaces, with $1.96 freight to Pittsburgh. Demand is very light, although perhaps improving a trifle, and prices seem to be quite firmly held.

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.30 — .31
Aniline oil, drums extra	lb.	.16½ — .17
Aniline salts	lb.	.24 — .26
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.25 — 1.30
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.75 — .85
Benzoic acid, U.S.P.	lb.	.60 — .65
Benzoate of soda, U.S.P.	lb.	.55 — .57
Benzene, pure, water-white, in drums (100 gal.)	gal.	.29 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.27 — .32
Benzyl chloride, 95-97 %, refined	lb.	.25 — .27
Benzyl chloride, tech	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.60 — .65
Beta-naphthol, tech	lb.	.27 — .30
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97–99%, straw color, in drums	gal.	.50 — .52
Cresylic acid, 95-97%, dark, in drums	gal.	.45 — .47
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	1.15 — 1.20
Dimethylaniline	lb.	.38 — .40
Dinitrobenzene	lb.	.23 — .25
Dinitroclorbenzene	lb.	.23 — .25
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.33 — .35
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Diphenylamine	lb.	.59 — .70
H-acid	lb.	.85 — 1.00
Meta-phenylenediamine	lb.	.90 — 1.00
Monochlorbenzene	lb.	.14 — .15
Monoethylaniline	lb.	1.20 — 1.25
Naphthalene crushed, in bbls.	lb.	.06 — .06½
Naphthalene, flake	lb.	.06½ — .07
Naphthalene, balls	lb.	.08 — .08½
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17½
Ortho-amidophenol	lb.	2.75 — 2.80
Ortho-dichlor-benzene	lb.	.15 — .20
Ortho-nitro-phenol	lb.	.75 — .80
Ortho-nitro-toluene	lb.	.12 — .15
Ortho-toluidine	lb.	.16 — .20
Para-amidophenol, base	lb.	1.25 — 1.30
Para-amidophenol, HCl	lb.	1.30 — 1.35
Para-dichlorbenzene	lb.	.15 — .18
Paranitroaniline	lb.	.75 — .77
Para-nitrotoluene	lb.	.70 — .75
Para-phenylenediamine	lb.	1.50 — 1.55
Para-toluidine	lb.	1.10 — 1.15
Phthalic anhydride	lb.	.35 — .38

Phenol, U. S. P., drums	lb.	.11½ —	15
Pyridine	gal.	1.75 —	2 75
Resorcinol, technical	lb.	1.30 —	1.35
Resorcinol, pure	lb.	1.75 —	1 80
Salicylic acid, tech., in bbls.	lb.	.20 —	21
Salicylic acid, U. S. P.	lb.	.22 —	23
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.25 —	28
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.10 —	12

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

GADSDEN—The E. J. Owen Co., 6th St., has preliminary plans under way for the erection of a new foundry for the manufacture of iron and other metal castings.

Arkansas

FORT SMITH—The Fort Smith Glass Products Co., recently organized, is arranging for the establishment of a local plant for the manufacture of bottles and other glass products, with initial output of about 40,000 bottles per day. C. M. Penn is president, and L. E. Duckworth, secretary and treasurer.

California

NATIONAL CITY—The Jet Oil Co., has acquired a local site for the erection of a new plant for the production of lubricating oils. The first unit is estimated to cost about $55,000. Plans will be prepared at an early date.

TEHACHAPI—The Henry Cowell Lime & Cement Co., 2 Market St., San Francisco, has acquired a tract of property in the vicinity of Tehachapi, and plans for the erection of a new cement-manufacturing plant and lime works. The plant will consist of a number of buildings, and is estimated to cost in excess of $750,000.

Connecticut

STAMFORD—The Stamford Foundry Co., Canal St., has had plans prepared for the construction of an addition to its plant, with improvements in the present foundry. Emmens & Abbott, Stamford, are architects.

TORRINGTON—The Anaconda Copper Co., 25 Broadway, New York, N. Y., has tentative plans under consideration for the erection of an addition to the plant of the American Brass Co., a subsidiary, at Torrington, to be equipped as a rolling mill.

Georgia

LUDOWICI—The McDonald Brick Co., operated by C. J. McDonald & Sons, is planning for enlargements in the local plant of the Ludowici Brick & Tile Co., recently acquired. The capacity will be increased to about 60,000 bricks daily. A number of improvements will be made also in the existing works.

Illinois

MATTESON — The new chemical plant to be erected here will be owned and operated by the K. I. Herman Chemical Corp., 332 South Michigan Ave., Chicago, and not by the Mid-West Box Co., Chicago, as recently noted in these columns. K. I. Herman, president of the chemical company, has been secretary and general manager of the Mid-West company, recently organizing the company bearing his name with a capital of $300,000, under Illinois laws. The plant will be 3-story, 60 x 140 ft. Harvey C. Miller, 112 West Adams St., Chicago, is architect.

CHICAGO—Fire, March 9, destroyed the north section of the plant of the Elaborated Ready Roofing Co., 44th and La Salle Sts., manufacturer of asphalt roofing products, comprising a 2-story factory with machinery. The loss is estimated at about $42,000.

Kansas

WICHITA—The Golden Rule Refining Co. is planning for the rebuilding of the section of its local oil refinery, destroyed by fire, March 6, at 29th St. and Topeka Ave.

CRESTLINE—The Kanok Metal Co. is considering tentative plans for the rebuilding of its concentrating plant, recently destroyed by fire with loss estimated at $45,000, including equipment.

Kentucky

NEWPORT—Officials of the Kentucky Rolling Mills Co. have organized the Andrews Steel Co., under Delaware laws, with capital of $750,000, and are reported to be planning for the erection of a new blast furnace and steel plant in the vicinity of Bay City, Mich., where options on property have been secured. The company is headed by Joseph B. and W. N. Andrews, Newport.

LOUISVILLE.—Ayer & Lord Tie Co., 80 East Jackson Blvd., Chicago, will build a 2-cylinder creosote plant here. The Leonard Construction Co. of Chicago will be in charge of material buying, which will consist mainly of steel tanks, creosote cylinders 130 ft. long by 7 ft. 6 in. diameter fabricated for 250-lb. pressure, tram cars, boilers, hydraulic pumps, air compressors.

Maryland

BALTIMORE—The American Sugar Refining Co. has filed plans for the erection of another building at its new sugar mill at Clement and Woodall Sts., to be 1-story, 62 x 73 ft.

BALTIMORE—The Colloidal Process Paint Co., Lexington Bldg., will expend about $30,000 for the erection of its new local plant, and will install equipment for a daily output of about 250 tons of bitumens. H. A. Hughes is secretary and treasurer.

BALTIMORE—The Mexican Petroleum Corp., 120 Broadway, New York, N. Y., will construct a new tankage and distributing plant on 1st St., to cost about $40,000. Work will be placed under way at once.

Missouri

CARUTHERSVILLE—The City Council will install a new water-purification plant in connection with extensions and improvements in the municipal waterworks. Black & Veatch, 701 Mutual Bldg., Kansas City, Mo., are engineers.

WEBB CITY—Fire, March 13, destroyed a portion of the refinery of the Wilhoit Oil Co. The estimated loss has not been announced; the loss in the tankage department approximated $30,000.

North Carolina

WILLETS — The Natural Abrasive Mining Co., Waynesville, N. C., is planning for the construction of a new grinding plant at its properties at Willets, with initial capacity of about 150 tons daily, estimated to cost about $100,000. An additional sum of approximately $200,000 will be used for development and general operatings, including new equipment. Frank R. Hewitt is treasurer.

New Jersey

TRENTON—The Semple Rubber Co. has acquired its leased plant on Murray St. for a consideration of about $40,000, consisting of a number of buildings, with adjoining site for expansion. The company manufactures inner tubes for automobile tires and other rubber products.

TRENTON—The Trent Brick Co., Princeton Ave., is considering plans for the rebuilding of the portion of its plant, recently destroyed by fire. A. W. Goulding is treasurer.

HOBOKEN—The Fisher-Sweeny Bronze Co., 1301 Grand St., is planning for the rebuilding of the portion of its plant, destroyed by fire, March 15, with loss estimated at close to $150,000, including equipment. The company specializes in the manufacture of bronze, brass and other metal castings.

EAST ORANGE—Plans have been prepared for the immediate installation of an automatic gas producer plant at the factory of the Ward Baking Co., Ampere section, 35 x 57 ft.

New York

GLENDALE, L. I.—The Conley Tin Foil Co., 521 West 25th St., New York, will soon break ground for the erection of a 1-story plant on Woodhaven Ave., Glendale, to cost about $175,000, including equipment. The general building contract has been let to the Foundation Co., 120 Liberty St., New York.

LOCKPORT—The A. W. Jack Corp., Mill St. and North Transit Road, manufacturer of asbestos millboard products, etc., is planning for the rebuilding of the portion of its plant, destroyed by fire, March 7.

Oklahoma

OKLAHOMA CITY— George Sohlberg and A. E. Kull, Oklahoma City, are organizing a new company, capitalized at $200,000, to establish a local plant for the manufacture of special metal castings.

MUSKOGEE—The Muskogee Vitrified Brick Co. is planning for the rebuilding of the portion of its plant recently destroyed by fire. F. C. Nicholson is president.

Pennsylvania

LANCASTER—The Armstrong Cork Co., Liberty and Mary Sts., will soon break ground for the erection of a 4- and 6-story addition to its plant, 50 x 215 ft. The general building contract has been let to Herman Wohlsen, Woolworth Bldg., Lancaster.

CHESTER—The Scott Paper Co., foot of Market St., has enlargements under way at its plant to increase the capacity about one-third. A number of improvements will be made in the present factory, including the installation of considerable new machinery. The work is estimated to cost about $450,000.

PHILADELPHIA—The Gulf Refining Co., Widener Bldg., has acquired property aggregating about 70 acres of land in the Girard Point district, as a site for the erection of a large distributing plant. Actual operations will be deferred until a later date. Wesley A. Looney is general manager.

Tennessee

NASHVILLE—In connection with its new plant at Old Hickory, the Nashville Pulp & Paper Corp. plans for the erection of a finished paper mill at a later date, with installation to comprise two 30-ton machines and auxiliary equipment. Three buildings are now in course of erection, with remodeling of a number of structures formerly used by the government. Equipment is being installed in the different plant departments and it is expected to commence production in a portion of the plant in May. R. J. Cullen is president and general manager.

Texas

DALLAS—The Davis Mfg. Co., Knoxville, Tenn., has construction under way on its new local plant for the manufacture of chemicals and chemical byproducts. It will be 3-story, totaling about 15,000 sq.ft. of space. The building will be owned by Dallas interests, and occupied under a long lease. It is planned to commence the installation of machinery at an early date. Grover C. Davis is president and general manager.

MARSHALL—The Darco Corp., Wilmington, Del., a subsidiary of the Atlas Powder Co., will proceed with the erection of three units of its new local plant, instead of limiting the work to a single unit, as originally planned. The construction is expected to require about 12 months. The plant will produce refined carbon for sugar, chemicals and other service, and when in full operation will give employment to about 1,000 operatives.

Virginia

RICHMOND—The Cauthorne Paper Co., Cary and Tenth Sts., has plans nearing completion for the erection of a new 4-story plant, and will commence erection at an early date. It will cost about $75,000. Carneal & Johnson, Richmond, are architects. R. A. Cauthorne is president.

West Virginia

ATHENS—The Town Council, in cooperation with the state, is arranging for the installation of a filtration plant in connection with the waterworks system, to be used, also, by the State Normal School. C. E. Collins, Drexel Bldg., Philadelphia, Pa., is engineer.

CHARLESTON—The Young Bros. Foundry Co., recently organized, is planning for the erection of a new 1-story plant for the manufacture of steel and other metal castings. R. M. and Walter Young head the company.

Washington

SPOKANE—The Bentley Paste Co., Minneapolis, Minn., is planning for the erection of a new branch plant at Spokane, for the manufacture of pastes and kindred products. V. E. Benley is vice-president.

New Companies

THE SPRINGFIELD MICA PRODUCTS CO., Boston, Mass., has been incorporated with a capital of $200,000, to manufacture mica products and affiliated specialties. William P. Heck is president; and F. L. Glover, 104 Coolidge Hill Road, Watertown, Mass., treasurer.

THE FEDERAL FIBRE CORP., New York, N. Y., has been incorporated with a capital of $50,000, to manufacture fiber products. The incorporators are R. C. Richter and E. T. Walton. The company is represented by J. G. Pekberton, 130 West 42d St., New York.

THE STANDARD BRICK CO., Macon, Ga., has been organized to manufacture brick and other burned clay products. The company will take over and consolidate the Bibb Brick Co., A. T. Small Brick Co. and the Cherokee Brick Co., all operating in this district. W. E. Dunwody is president.

THE DYSCO CHEMICAL CO., West Hoboken, N. J., has been incorporated with a capital of $50,000, to manufacture chemicals and chemical byproducts. The incorporators are Charles Rose and Carnig Ajamian. The company is represented by Charles Ajamian, 515 Bergenline Ave., West Hoboken.

THE HIGBIE SALT CO., 111 West Washington St., Chicago, Ill., has been incorporated with a capital of $50,000 to operate salt properties and manufacture salt byproducts. The incorporators are Fred K. Higbie, M. J. Haggerty and W. B. Nay.

THE PITT PAINT CO., Beaver, Pa., has been incorporated with a capital of $5,000, to manufacture paints, varnishes, etc. C. D. Miller, Wilkinsburg, Pa., is treasurer.

THE FRENCH-AMERICAN ENAMEL MFG. CO., Wilmington, Del., has been incorporated under state laws with capital of $100,000, to manufacture paints, enamels and kindred products. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington.

THE MODEL BRICK CO., Houston, Tex., has been incorporated with a capital of $10,000, to manufacture brick and other burned clay products. The incorporators are W. J. Carter and J. F. Meyer, both of Houston.

THE INTERNATIONAL RUBBER CO. OF AMERICA, Wilmington, Del., has been incorporated under state laws with a capital of $20,000,000, to manufacture tires and other rubber products. The company is represented by the Corporation Service Co., Wilmington.

THE PLATINUM METALS RESEARCH SYNDICATE, Grants Pass, Ore., has been incorporated with a capital of $50,000, to manufacture refined metals and engage in metallurgical experiments. The incorporators are Morton Webster and Henry M. Lancaster, both of Grants Pass.

THE NON-CORROSIVE PAINT CO., New York, N. Y., has been incorporated with a capital of $100,000, to manufacture metallic and other paints. The incorporators are A. Berman, J. P. Segal and R. Arenwald. The company is represented by I. Gainsburg, 258 Broadway, New York.

THE NORMA LABORATORIES, INC., Albany, N. Y., has been incorporated with a capital of $10,000, to manufacture chemicals and affiliated products. The incorporators are L., C and R. P. Branche. The company is represented by C. R. Watson, Albany.

THE CRESCENT RUBBER CO., Trenton, N. J., has been incorporated with a capital of $25,000, to manufacture rubber products. The incorporators are Martin M. Glassman, A. Abrahams and John L. Heher, 150 East State Street, Trenton.

THE CARBO BRICK CO., Berlin, Conn., has been incorporated with a capital of $100,000, to manufacture vitrified brick, terra cotta tile, etc. The incorporators are John Carbo, Edward J. Lardner and M. M. Lardner, all of Kensington, Conn.

THE BUTLER SILICA CO., Butler, Pa., has been incorporated with a capital of $15,000, to manufacture silica products. George B. Lambert, Butler, is treasurer.

THE SNEEZO CO., INC., 40 North Dearborn St., Chicago, Ill., has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are J. Lewis, J. C. Turner and M. C. Suhr.

THE APOLLO FOUNDRY, INC., Brooklyn, N. Y., has been incorporated with a capital of $25,000, to manufacture iron, steel and other metal castings. The incorporators are represented by I. W. Eckstein, 61 Park Row, New York.

THE REX CHEMICAL CO., Washington, D. C., has been incorporated under Delaware laws with capital of $1,000,000, to manufacture chemicals and chemical byproducts. The incorporators are G. Victor Yonce and R. B. Sheldon, Salem, Va.; and Eugene A. Chanaberry, Washington. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington, Del.

THE NACCO CHEMICAL CO., 191 Market St., Newark, N. J., has filed notice of organization to manufacture chemical products. James A. Dennis, 34 South Tenth St., heads the company.

THE ROME FIREPROOFING CO., Rome, Ga., has been incorporated with a capital of $100,000, to manufacture brick and other burned clay products. The company will succeed to the plant and business of the Rome Brick & Tile Co. The incorporators are H. H. Woodruff, Rome; and B. Mifflin Hood, Atlanta, Ga. The last noted is head of the B. Mifflin Hood Brick Co.

E. E. ZIMMERMAN, INC., Pittsburgh, Pa., has been incorporated with a capital of $35,000, to manufacture paints, varnishes, etc. I. M. Anderson, 3874 Perrysville Ave., Pittsburgh, is treasurer.

THE NEW YORK LABORATORIES, INC., New York, N. Y., has been incorporated under Delaware laws, with capital of $250,000, to manufacture chemicals and affiliated products. The company is represented by the Delaware Registration Co., 900 Market St., Wilmington, Del.

THE IROQUOIS OIL CORP., 118 North La Salle St., Chicago, Ill., has been incorporated with a capital of $10,000, to manufacture petroleum products. The incorporators are John H. and Robert C. Quirk, and O. S. Springer.

THE SUPREME LEATHER CO., 131 New Jersey Railroad Ave., Newark, N. J., has filed notice of organization to manufacture leather products. James A. Veneziano, 201 Parker St., heads the company.

THE MOHAWK BRICK CO., Mechanicville, N. Y., has been incorporated with a capital of $20,000, to manufacture brick and other burned clay products. The incorporators are J. Vett and C. D. Agonisto. The company is represented by F. A. Tate, Mechanicville.

THE PIONEERS CONSOLIDATED PETROLEUM CO., Wilmington, Del., has been incorporated with a capital of $250,000, to manufacture petroleum products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE FRENCH POLISH MFG. CO., 4716 Dorchester Ave., Chicago, Ill., has been organized to manufacture polishes and other chemical specialties. The company is headed by Fred W. Bentley and Jean B. Hassewar.

THE COLORLAKE CHEMICAL CO., New York, N. Y., has been incorporated with a capital of $10,000, to manufacture colors, chemicals, paint products, etc. The incorporators are R. E. Mertens, W. D. Goss, Jr., and H. G. Sidebotto. The company is represented by H. B. Corey, 290 Broadway, New York.

THE HUBBELL RUBBER CO., Wilmington, Del., has been incorporated under state laws with a capital of $600,000, to manufacture tires and other rubber products. The company is represented by the Corporation Registry Co., 900 Market St., Wilmington.

THE ZENITH PAINT & COLOR CORP., New York N. Y., has been incorporated with a capital of $125,000, to manufacture paints, varnishes, etc. The incorporators are G. and G. W. Miller, and S. Glasner. The company is represented by S. C. Sugarman, 1540 Broadway, New York.

THE ATLAS BULB CO., 289 Valley Road, West Orange, N. J., has filed notice of organization to manufacture glass bulbs and other glass products. The company is headed by M. D. Grove and Joseph A. Dorrity.

THE LOOP STEEL MFG. CO., Ponca City, Okla., has been incorporated with a capital of $500,000, to manufacture steel products. The incorporators are J. B. Hinkle, Ponca City; Swan C. Burnette, Pawhuska, Okla.; and C. H. Loop, Arkansas City, Kan.

THE BRITITE CHEMICAL CO., New York, N. Y., has been incorporated with a capital of $6,000, to manufacture chemical products for rust prevention and other service. The incorporators are L. M. Flohr, A. Rich and S. Schoening. The company is represented by J. H. Marsh, 220 Broadway, New York.

THE WALLACE OIL & REFINING CO., Wilmington, Del., has been incorporated under state laws, with capital of $500,000, to manufacture refined oil products. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington.

THE UTICA PAINT REMOVER CORP., Utica, N. Y., has been incorporated with a capital of $50,000, to manufacture chemical products. The incorporators are G. A. Armstrong and F. J. Matteson. The company is represented by W. S. Matteson, 400 Broadway, Utica.

THE NATIONAL LEAD-CONSTRUCTION CO., Jenkintown, Pa., has recently been formed. C. H. Kimberly is president. At present the company is interested in designing and installing all classes of lead work and will later enter the equipment field.

THE GREAT EASTERN GASOLINE REFINING CO., New York, N. Y., has been incorporated under Delaware laws, with capital of $500,000, to operate an oil and gasoline refining plant. The incorporators are Thomas P. Hall, Charles Sears and John G. Powers. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington.

Capital Increases, Etc.

THE CHICAGO HEIGHTS OIL MFG. CO., 140 West Van Buren St., Chicago, Ill., has filed notice of increase in capital from $45,000 to $100,000.

THE HUMPHREYS-MEXIA CO., Mexia, Tex., operating oil refineries, has filed notice of change of name to the Humphreys Oil Co., at the same time increasing its capital from $10,000,000 to $15,000,000.

THE NEW YORK COAL-TAR PRODUCTS & CHEMICAL CO., recently incorporated under Delaware laws with capital of $1,000,000, has filed notice of charter at Albany, N. Y., to operate in New York. The company is represented by I. D. Shneller, 25 West 43rd St., New York.

THE SINCLAIR CONSOLIDATED OIL CORP., 45 Nassau St., New York, N. Y., operating oil refineries, is disposing of a bond issue of $45,000,000, the proceeds to be used for general financing and operations.

THE DEFAY RUBBER WORKS, 45 North Third St., Easton, Pa., has filed a voluntary petition in bankruptcy.

THE STANDARD OIL CO. OF KENTUCKY, Louisville, is arranging for an increase in capital from $6,000,000 to $12,000,000.

Stockholders of the RYDON TIRE & RUBBER CO., 765 Broad St., Newark, N. J., are arranging for a dissolution of the corporation. Edgar J. Haaren is secretary.

THE CELLULOSE PRODUCTS, INC., 1459 Broadway, New York, N. Y., has arranged financing plans for increased operating capital, to be used for general expansion in production.

THE PHOENIX RUBBER MFG. CO., Boston, Mass., has filed an involuntary petition in bankruptcy.

THE AIR REDUCTION CO., 342 Madison Ave., New York, manufacturer of welding apparatus, has acquired the plant and business of the Davis-Bournonville Co., Van Wagnen Ave., Jersey City, N. J., manufacturer of oxy-acetylene equipment, and will operate the property as a subsidiary.

Industrial Notes

THE BONE CHAR PRODUCTS CO., LTD., of Allentown, Pa., recently sold its bone oil recovery plant to L. Martin Co. of New York, by the receiver, D. S. Chamberlin. The consideration was $20,000. A process for the recovery of bone oil by the use of a volatile solvent, chiefly benzene, was tried out at this plant, but was not commercially successful. It is understood that the New York company will use the plant as a storage warehouse.

HAROLD G. MANNING, chemical engineer and patent lawyer, who opened an office last April in Waterbury, Conn., has now changed his location to the new Waterbury National Bank Bldg., 193 Grand St., that city.

E. F. DREW & Co. has been incorporated at Albany, N. Y. The assets of E. F. Drew & Co., which have been in custody of the courts for the past few months, have been turned over to the new organization and the business of the company, its subsidiaries and its branches will be conducted as formerly.

THE SURFACE COMBUSTION CO., New York, has obtained the exclusive license for exploiting in this country and in foreign countries the Andrews rustproofing process which was used during the war by the British Government.

THE ALTAU CO., Balboa Bldg., San Francisco, Cal., is engaged in the development of deposits of fullers earth, diatomaceous earth and talc in California and Nevada.

W. S. ROCKWELL CO., New York, announces that Gibbons Bros., Ltd., Dudley, Worc., England, has been appointed its representative for the British Isles.

THE NATIONAL PACKAGING MACHINERY CO., Jamaica Plain, Mass., announces the appointment of John C. Kay as New York City representative, with offices at 90 West Broadway.

THE PETROLEUM IRON WORKS CO. announces the appointment of J. A. Connelly.

formerly manager of the Tampico, Mexico, office, as sales manager, with headquarters at Sharon, Pa.

HERVEY J. SKINNER of Skinner, Sherman & Esselen, Inc., chemist and engineer, of Boston, has been selected as technical adviser by the Associated Industries of Massachusetts. The executive committee of that organization recently decided to establish a technical information service similar to its legal, taxation, accounting, insurance and banking services. The new technical information service, to be conducted by Mr. Skinner, will answer inquiries on industrial processes used in manufacturing operations. It will be in a position to advise members on technical subjects and to give general information that will be of material assistance in solving industrial problems. Care will be exercised to discriminate between information which should be furnished free and that for which members of the Associated Industries of Massachusetts should retain a competent firm of engineers.

THE HARDER FURNACE & ENGINEERING CORP. announces the sale of its licenses to use the Harder patents and of the services of its engineering department of the Fuels Utilization Corp., Knickerbocker Bldg., 152 West 42nd St., New York City. The Harder Furnace & Engineering Corp. will move to that address and occupy adjacent offices.

THE ORTON & STEINBRENNER CO., Chicago, Ill., manufacturer of locomotive cranes, clam-shell and orange-peel buckets and coal crushers, has made arrangements with Walter Hasendahl, 1213 Fuller Ave., Los Angeles, Cal., to act as representative in southern California.

LLOYD A. HALL has severed his connection as manager of Vodin, Inc., to establish business on his own account under the name of the Chicago Chemical Products Co., 6148 Wentworth Ave., Chicago. This company is engaged in a general line of manufacture, including toilet specialties, insecticides and automobile polishes.

THE WILSON WELDER & METALS CO., New York, announces the appointment of R. L. White as district manager in charge of the Detroit office.

THE GEORGE J. HAGAN CO., Pittsburgh, Pa., has opened two new offices. One is at 20 East Jackson Boulevard, Chicago, in charge of V. A. Hain, and the other in the Murphy Bldg., Detroit, in charge of J. Sandberg.

J. T. DONALD & CO., LTD., chemical engineer and consulting chemist, of Montreal, announces its removal to new and larger premises at 40-42 Belmont St., which the company has purchased and specially equipped for its laboratory and consulting work.

THE PNEUMERCATOR CO., INC., manufacturer of pneumatic mercury gages for measuring liquid contents of tanks, has moved its factory from Philadelphia, Pa., to the Sperry Bldg., 40 Flatbush Ave. Extension, Brooklyn, N. Y. Its general offices will be transferred from 15 Park Row, New York City, to the new factory location.

THE ARMSTRONG CORK CO., Pittsburgh, Pa., has opened a new office in Milwaukee, Wis., at 1011 Majestic Bldg. Hugh Krampe is in charge. It is also announced that the Denver office has been reinstated and is in charge of Alexander Callow.

THE DAYTON-DOWD CO., Quincy, Ill., announces the opening of a district office in Pittsburgh at 809 Keenan Bldg., covering the sale of centrifugal pumps and Underwriters' fire pumps. The office will be in charge of T. J. Barry, who for the past several years has been connected with the home office on engineering and sales.

WALLACE & TIERNAN CO., INC., Newark, N. J., announces the opening of an office in the McKnight Bldg., Minneapolis, Minn., which is in charge of B. M. Conaty, formerly of its Chicago office. This new district will cover the states of Minnesota, North Dakota, South Dakota and Montana, and the Canadian provinces of Alberta, Saskatchewan and Manitoba. It is also announced that E. M. Lawson, formerly of its San Francisco office, has become its representative at Kansas City, located at 707 Commerce Bldg.; that R. B. Mowry has recently been appointed its representative for the New Jersey, Delaware and Maryland districts, and will be located at the Newark, N. J., office; that Wallace & Tiernan, Ltd., was recently organized with headquarters at 73 Adelaide St., East, Toronto, Ont., Canada, in charge of J. Van Benschoten; that several additions have been made to its technical force recently, including S. H. Gregg and G. I. Nelson, who will become attached to the personnel of its Chicago office; A. LoPrest, who will become attached to the San Francisco office; R. M. Finch, who will be attached to the main office at Newark, N. J., and also that in the main office sanitary and industrial sales will be handled separately—L. H. Goebel becoming manager of industrial sales and R. V. Donnelly becoming manager of sanitary sales.

THE MEDART PATENT PULLEY CO., St. Louis, Mo., announces the change of its corporate name to "The Medart Company."

THE READ MACHINERY CO., York, Pa., recently held its ninth annual convention of the executives and sales representatives. The keynote of the convention was the same as in former years, "Better Service to the Chemical Industries."

F. W. REISMAN and L. E. TURK, formerly traveling sales manager and treasurer, respectively, of the Quigley Furnace Specialties Co., New York, have organized and incorporated the Keystone Refractories Co. and will manufacture high-temperature cement and granular refractories. The office is located at 122 Liberty St., N. Y., and the factory is in Jersey City.

THE MCCLAVE-BROOKS CO., Scranton, Pa., has appointed A. R. St. John as manager of the New York office, succeeding S. G. Smith, whose resignation took effect last January. Mr. St. John was formerly in charge of the Boston office. It is also announced that K. S. Holmes, Jr., has been appointed a representative of this company in Cincinnati, with offices in the Gwynne Bldg., and that the office at Charlotte, N. C., has been moved to Greenville, S. C.

THE HAUCK MFG. CO., Brooklyn, N. Y., has removed its Philadelphia office to 1726 Sansom St. Herbert Vogelsang, who has been connected with the company for 6 years, will be in charge.

THE COLORADO SOCIETY OF ENGINEERS at its recent annual meeting and banquet elected the following officers: President, R. M. Hosea; vice-president, W. M. McMechen; secretary-treasurer, C. M. Lightburn; directors, F. C. Dreher, I. C. Crawford, J. S. DeRemer, R. G. Hosea, F. C. Steinhauer, R. J. Randall, V. A. Kauffman, C. B. Daniels.

THE PACIFIC CHEMICAL CO. is now located in its new quarters at 70 Cliff St., New York.

THE RATHBUN JONES ENGINEERING CO., Toledo, O., has appointed the Ingersoll-Rand Co., New York, general sales agent for Rathbun gas engines.

Dr. BAXERES DE ALZUGARAY, consulting chemist and metallurgist, announces the removal of his office and laboratory to 23 Washington St., New York.

THE PITTSBURGH TESTING LABORATORY, Pittsburgh, Pa., announced at its recent annual meeting the retirement of its president, George H. Clapp, his reappointment as a member of the board of directors of the company, and the election of Colonel James Milliken to the presidency of the company. Colonel Milliken's experience as a mechanical officer of the Pennsylvania Railroad Company, his experience in designing, constructing and in the shipment of all manner of the railroad equipment for the military railways shipped to France during the war and his subsequent experience fit him for the operation of this company.

THE SHALE OIL & REFINING CORP. has changed its name to "Industrial By-Products, Inc." but is still located at 25 Broadway, New York City.

THE SARGENT PAINT CO., of Indianapolis, Ind., has changed its firm name to "The Sargent-Gerke Co."

THE CHICAGO FLEXIBLE SHAFT Co. has resumed its St. Louis office, which is located in the Railway Exchange Bldg. It is in charge of J. J. Wittenburg, who has been with the Chicago office of the company for 3 years.

THE NORWALK IRON WORKS CO., South Norwalk, Conn., announces a number of changes in the executive personnel of the organization. The executive staff is now as follows: C. L. Thompson, president and general manager; Howard E. Adt, first vice-president; Harold B. Knowles, treasurer and assistant secretary; Thomas M. Steele, secretary; A. R. Betts, vice-president in charge of sales; W. E. Mathews, vice-president in charge of manufacturing and engineering; G. W. Wardwell, chief engineer; W. M. Greene, general superintendent.

The "Informashow" is the name of the exposition to be held at Exposition Park, Rochester, N. Y., May 15 to 20, under the direction of the Purchasing Agents Association of Rochester, N. Y., which is affiliated with the National Association of the Purchasing Agents.

THE C. W. HUNT CO., INC., of West New Brighton, Staten Island, N. Y., announces the reestablishment of its New York City office at 143 Liberty St. It has taken over all the sales and engineering work which has heretofore been carried on by its subsidiary company, the C. W. Hunt Engineering Corp., for the past 18 months, as the business of this latter corporation has now been consolidated with the C. W. Hunt Co., Inc.

THE BLAW-KNOX CO. has moved its New York office from the City Investing Bldg. to the Carbide & Carbon Bldg., 30 East 42nd St.

THE WORTHINGTON PUMP & MACHINERY CORP., New York, calls attention to Bulletin W-605, which is an instruction book for centrifugal pumps. There are informative data on the erection and installation of centrifugal pumps, a curve showing the maximum water temperature permissible for different suction lifts and curves showing the head capacity and efficiency capacity characteristics of the centrifugal pump. The bulletin is well illustrated. Copies will be sent upon request.

THE VULCAN SOOT CLEANER CO., DuBois, Pa., has recently issued Bulletin 548, on the use of Vulcan cleaners with Stirling boilers and Bull. 451, on B & W type boilers.

Coming Meetings and Events

AMERICAN CHEMICAL SOCIETY will hold its spring meeting at Birmingham, Ala., April 4 to 7, 1922.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Baltimore, April 27, 28 and 29, 1922. Headquarters will be at the Emerson Hotel.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Rochester, N. Y., during the week of June 5, 1922. Meetings will be held in the spring instead of in the fall as heretofore

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its summer meeting at Niagara Falls, June 19 to 22. Headquarters will be at the Clifton Hotel.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its nineteenth annual meeting at Bigwin Inn, Bigwin Island, in the Lake of Bays district, Ontario, Canada, on June 21, 22 and 23.

AMERICAN OIL CHEMISTS' SOCIETY will hold its annual meeting at the Grunewald Hotel, New Orleans, La., May 8 and 9.

AMERICAN SOCIETY FOR STEEL TREATING will hold a sectional meeting at the Bureau of Mines auditorium, Pittsburgh, Pa., on May 25 and 26. The International Steel Exposition and Convention of the society will be held in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-fifth annual meeting June 26 to July 1, at Atlantic City, N. J. Headquarters will be at the Chalfonte-Haddon Hall Hotel.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY will hold a meeting at Lyons, France, June 27 to 30.

IRON AND STEEL INSTITUTE (British) will hold its annual meeting on May 4 and 5 at the House of the Institution of Civil Engineers, Great George St., S. W., 1, London.

NATIONAL ASSOCIATION OF PURCHASING AGENTS EXPOSITION (the "Informashow") will be held in connection with the seventh annual convention of the association at Exposition Park, Rochester, N. Y., May 15 to 22.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY and the AMERICAN PULP AND PAPER ASSOCIATION will hold annual meetings at the Waldorf-Astoria, New York, the week of April 10.

The following meetings are scheduled to be held in Rumford Hall, the Chemists Club, New York: April 21—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting; May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting: June 9—American Chemical Society, regular meeting.

"Executives Are Urged to Co-operate"

PROMPT return of monthly oil refinery figures would materially improve the production reports issued by the Bureau of Mines. This fact is the occasion for the request made by that bureau recently from which the title of this editorial is quoted. The bureau well says that "there is need for prompt co-operation, in view of the great value of these data to the oil refiner," for it is the industry itself which profits or loses according as the results are complete and promptly available, or incomplete and late.

Moreover, this is not an isolated case in which co-operation of industry with government investigations is important. At the present time the Bureau of the Census is making its biennial survey of the manufacturing industries. The results of that survey will be of tremendous importance to business, particularly to each business from which statistics are gathered. Co-operation with the census is therefore very important to business itself.

Reliable statistics are tools of great importance in planning production, distribution or sales. A knowledge of recent and current market prices is of no greater value to an industry than similar current data of production, distribution or stocks on hand. Where such figures are not already being gathered industry should set about having them made accessible promptly. And in the meantime those who are getting more or less belated returns now should see to it that the laggards in their industry speed up in order to permit quick, complete reports within those fields already covered either by government or association work. The value of the statistics is greatly enhanced by promptness, and the co-operation or lack of co-operation by the industry itself will altogether determine this factor.

The Strain Of War

PHYSICAL tests of army officers which have lately been in progress show "the most clear-cut evidence of physical deterioration" due to the "strain incident to the prosecution of the world war." It is found that they suffer from "instability of the nervous system," "an unnatural tendency to worry, fatiguability, low blood pressures and a lowered resistance to infectious disease," and that they show a "tendency toward increased introspection and mental exaggeration" of all forms of worry and mild physical ills. Blood pressures are abnormally high in men over 45, and among younger officers of 25 to 30 it is abnormally low.

What else should we expect? War is and always has been a debauch of anger. Active war experience is replete with shocks due to insomnia, muscular exertion, emotional excitation and physical injury. According to Dr. GEORGE W. CRILE of Cleveland, these cause histological changes in the brain, the suprarenals and the liver, and while some of his conclusions as to the wounding of the brain by shock have been questioned by his colleagues, we know that, in the main, experiences of this sort do cause injury, and these medical examinations prove it.

There has been a terrible let-down in reasonableness all over the world. Such instability of the nervous system, unnatural tendency to worry, chronic introspection and exaggeration of all sorts of ills do not apply to army officers alone. It is far more general. We have, all of us, been under great strain, and many of us are not over it yet. Some of us are permanently injured.

War upsets the mental balance, injures the understanding and the effectiveness of both victor and vanquished. History offers a leading example to which we have paid too little attention, because it was our own European forbears who did the damage. The Arabs maintained a wonderful civilization in Spain and Portugal. Their gardens were gardens of delight, and the remnants of their architecture indicate a cultivation and development that was far beyond that of any part of Europe for many centuries. It is among them that we find the beginnings of science as distinguished from abstract philosophy. We know but little of GEBER —but in chemistry we begin with him. The Arabs were also physicians and astronomers, and they gave us our numbers.

Then we good Europeans took up the white man's burden, and we drove the Arabs out. We disagreed with them on certain points of what is sometimes called "revealed truth" and we routed them utterly. We got into the habit of fighting them and hating them. And we conquered their proud spirit. We killed all those wholesome doubts within them which are the very foundations of science and which lead to inquiry and thought. We drove them back to their own traditions —and they have been living on them ever since; intellectually living on nothing but traditions. We spoiled them for a thousand years.

How much of their chemistry did we take from them? Nothing but the cheapest, easiest necromancy; the get-rich-quick foible of turning baser metals into gold. Why hadn't we better taste or more discrimination in our stealing? Because the wars had injured us white folks very much as they had injured the Arabs. For over half a millennium we were a low-lived lot.

When ERASMUS, with his great vision, saw the possibilities of chemistry and induced PARACELSUS to study it, the stage was set for progress, but there was still so much war going on, with its pernicious sequelæ, that the result was far more quackery than honest research. Even old GLAUBER used to sell love-potions.

And it was not until the seventeenth century that ROBERT BOYLE made chemistry the profession of a gentleman.

The big war has hurt everybody, victors and vanquished. We've all gone off in our competence, our understanding, our level-headedness. We're excitable, nervous, hysterical. Look at the United States Senate, the House of Representatives, at every parliament in existence! The members behave like wayward children. Honest debate has become almost a lost art. It is time to steady ourselves and to think straight. We have big jobs ahead of us and we are not ready for them. One of these big jobs is for us white folks to get along together, to understand one another, to stop yelling and to be decent as well as sensible. Army tests during the draft indicate that 40 per cent or more of the people of the United States do not develop mentally above the age of 10 or 12 years. Some of these children occupy high offices and they prove the fact every day.

Be a Good Neighbor —It Pays

THE man who has a job in a factory or plant located in a suburban section usually considers himself fortunate, for the surroundings are pleasant and comfortable and working conditions in general much more agreeable than in congested locations in the heart of a city. The residents of such suburban districts, on the other hand, usually do not welcome factories for next door neighbors, and often with good reason. However, under modern conditions with up-to-date ideas of how to operate a plant, the objections to most types of factory are rapidly disappearing. One of the largest factors in this change is the approved method of boiler and power plant operation which is now possible.

No one likes to live next door to the proverbial boiler factory. The noise from such an establishment is, of course, quite objectionable. But it is no less objectionable to the housewife to live near a beautiful factory building artistically designed and surrounded by beautiful lawns if the power plant of the establishment belches forth black smoke and spots the clothes on Monday and soots up curtains and furnishings all the rest of the week. Proper boiler design and operation will eliminate this factor without difficulty.

There is no reason, with modern equipment and modern methods of firing, for making any objectionable quantities of smoke or dirt. Coal can be received and ashes removed without serious nuisance to surrounding buildings or residences. The smoke or gases from the stack can be made quite unobjectionable. In other words, there is no reason why the power plant of any commercial establishment should cause the institution as a whole to be an undesirable neighbor.

If those who are planning and those who are operating will bear these facts in mind they can contribute their part toward more satisfactory plant locations. And with more satisfactory plant location will come better satisfied operatives. Everyone from the president in his mahogany-furnished office to the stoker or ash handler will enjoy being in a neighborhood where a few lawns and a few trees are possible instead of only brick alleys and the congested backyards of the factory district. It will pay well for the power plant to make itself a good neighbor.

Are Technical Editors Timid?

THE other day a manufacturer friend of ours told us that he did not think the editors of technical papers were courageous. When we asked him to be specific, he stated that, as a class, we were afraid to publish the facts about a new development unless it had been thoroughly tried and proved successful. As an example, he told of a new application of his company's product, which has been made at the request of a customer. This has been carefully worked out from an engineering standpoint and has been tried experimentally, but as yet has not been put to practical use. Our friend thought that under the circumstances we would not be willing to give the matter any editorial attention.

This is indeed far from the facts. We wonder how such misconceptions arise and how far they spread. One of the prime functions of a technical paper is to present the news of its field. Naturally, nothing can be published without sufficient examination to convince us that the principle involved is sound and that the source of our information is reliable. But when we can obtain news of a worth-while attempt to advance engineering practice, our first duty, provided the originator is willing, is to pass the information on to our readers. Often we are enjoined to secrecy. When publicity is earnestly sought it is too often for its advertising value.

No, our friend is mistaken. When he is ready to give us permission to do so, if we find his new development of interest to our readers, we shall be willing and glad to bring it to their attention.

Railroad Earnings And Service

THE new practice of considering economic questions quantitatively may well be applied to the so-called railroad problem. It may be putting it rather strongly to say that the old-fashioned "political economy" represented theory, while quantitative economics represents facts, but the difference is of that character, at any rate.

A report is now available for the full calendar year 1921 as to the earnings of the railroads, the net railway operating income having been $614,810,531, while 6 per cent on the tentative valuation (a trifle under 19 billion dollars) would be $1,115,940,000, according to the computation of the Bureau of Railway Economics. Thus the rate actually earned was 3.31 per cent. In the first 2 months of the year there were deficits, earnings then increasing to a maximum of 5.01 per cent for August, and dwindling thereafter to a rate of 3.44 per cent for December.

In this question of where railroad rates should be fixed, therefore, there is an amount of money involved, to be paid by the public or to be saved by the public, of less than half a billion dollars a year. No one states any definite figure, hence it is necessary to guess the amount of money folks are talking about, using as a basis the figures cited above.

The National Bureau of Economic Research last year studied the income of the American people for the years 1909 to 1918 inclusive, and found the income in 1913, the last pre-war year, to have been about 35 billion dollars, while for 1918 it was 61 billion, the increase being due chiefly to the advance in prices, for

the bureau concluded that the 1918 income reduced to 1913 dollars would be about 39 billion.

Merely the roughest sort of guesses are sufficient to reduce the present question to a quantitative basis. As such guesses we may take 40 billion as the present income and 50 billion as the income if business were "good," as those who wish railroad rate reductions argue would be the case if the reductions were made. Taking the 50 billion, one finds that the outside amount at stake in the rate discussion is 1 per cent of the national income.

From the quantitative viewpoint, therefore, the question is whether an amount of money equal to 1 per cent of the national income can have much effect upon the conditions that produce the income. One is entitled to have doubts. It is argued, however, that high freight rates interfere with certain kinds of business, and it may properly be claimed that it is unfair to set the half billion dollars against the whole 50 billion. However, a scrutiny of ton-mileage freight movement and railroad revenue in 1921 does not indicate that the heavy and low-priced commodities suffered more than the very valuable commodities, in which freight rates cut little figure. Some heavy commodities, like coal and iron ore, had a restricted movement in 1921, but it could scarcely be shown that a mere reduction in freight rates would have produced a normal movement.

Further objection to the quantitative comparison may be made, that even if freight rates are not vital from the money standpoint, their remaining unliquidated has a bad psychological influence. That is another story, and there may be something in it, though scarcely a great deal.

On the other side of this question is the matter of railroad service. Greatly increased business activity in the United States cannot be expected if the railroads cannot handle the accompanying movement, and there is impressive testimony that the railroads as now physically constituted cannot stand any great increase in load.

From that angle the question is whether the people can spare something like 1 per cent of their income as insurance against a transportation breakdown in case business tries to become very active.

How Things May Look In a Hundred Years

WE CHILDREN OF LIGHT of these days are not so very wise, after all! Let's imagine ourselves living in 2022, and discussing in some library rich in contemporary documents the economic history of the first quarter of the twentieth century. One of our number might pick up an advertising brochure of an important chemical manufacturing concern dated 1922.

"Here's an interesting note!" he might exclaim. "It is a chapter headed 'Publicity Harmful,' and the vapid excuse given is that if it were known that they were busy in the development of any product, before they were making enough to supply all who ask for it, some one customer might gain an advantage over another. As an actual reason it is so frail that it is funny, but it is of value as showing that they recognized the need of some sort of an excuse for their secrecy.

"Secrecy was the bane of chemical industry in those days. The dye industry, for instance, was having a hard time to get started in the United States. Before the Great War Germany had practically a monopoly, and during the war there was pressing need to produce, although the Americans were without intermediates, except aniline. You'd think, with a whole industry eating its heart out for intermediates, for beta naphthol, H acid and a whole string of others, that they would have made common cause in research, wouldn't you? But that wasn't the way they did things in those days. The Sherman act threatened them with all the thunders of the law if they did not compete in selling. Any co-operation was thought to be dangerous, whether it was or not. And this worked against public interest, because its effect was to discourage manufacturers from working together to reduce their costs. There was really nothing to hinder them except that it was contrary to tradition.

"Tradition ruled throughout most branches of chemical industry. Everything was locked up tight in front with a constant but slow leakage going out of the back doors, while chemists were often actually forbidden to exchange ideas with other chemists. The veil of commercial tradition still covered nearly all kinds of manufacture. Why, do you know there were some concerns that used to pay $50,000 a year for legal advice and $5,000 a year for scientific guidance in chemical industry!" The speaker would then probably have to prove that he was not joking.

Another might refer to the farmers of the Middle West, who burned corn as fuel because they could not dispose of it, while millions were starving in Russia for lack of that very corn and many hundreds of steamships were laid up in idleness with plenty of coal available and seamen out of work. "That tragedy," it might be remarked, "was due to the fact that they were so tied up by system that they could not count anything but dollars. Not one man in ten thousand knew calculus or could integrate."

"Still another tragedy of those days," one of the company might say, "was the Lesser Antilles. Those jewels of the sea, the loveliest places on the globe—that LAFCADIO HEARN wrote about, for instance, in his classic 'Two Years in the French West Indies,' where everything will grow, where nobody need starve, where the sea swarms with fish, where both summer and winter breezes are the balmiest that blow—were practically out of use. Sugar in the lowlands could not compete with Cuba and Porto Rico; coffee in the uplands could not compete with Brazil, and the trade in citrus fruits was held elsewhere. It was not a question of costs; it was a question of facilities and transportation and co-operation and thought. All this time the natives were gradually drifting back to the condition of savagery that reigned in Haiti and Santo Domingo. The most beautiful islands in the world were relegated to the rubbish heap. "

"What was the matter?" one might ask.

"Well," another might reply, "my theory is that the principal trouble of those days was a curious delusion in which men undertook to do business as though they were lawyers trying a case in court. Everybody strove to put his competitors into a hole—and nearly everybody succeeded. It was the lazy way, to succeed by a trick. They hadn't learned the rule for industrial success: to aid the industry in which you are engaged by every possible means, to scorn secrecy as bad form and as the weapon of the incompetent, and then to have wit enough to keep ahead of the game. Only a few men engaged in industry had seen this light in those days."

Then we should all agree that the ways of 1922 were pretty crude.

Readers' Views and Comments

Electrolytic Iron a Commercial Product

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to the article appearing in your issue of Jan. 18, page 128, "Electrolytic Iron a Commercial Product." This is extremely interesting, but I notice a statement at the bottom of column 2 of the article as follows: "For example, the circulation of the electrolyte, always maintaining it up to the desired standard of iron content . . . This is the novelty introduced by Frederick A. Eustis and Charles P. Perin." This I would point out is not novel. The utilizing of certain ores as raw material is, of course, beneficial and presents no difficulty. The precipitation of the copper, if any, by the usual and well-known method can also be easily effected.

The difficulty, of course, is not in any of these things, but principally in maintaining the electrolyte neutral on a large-scale plant and producing iron without the aid of trick methods free from hydrogen craters—every time.

Davenham, Cheshire, England. S. HUTCHINS.

An Outline of the Uses of Lime

To the Editor of Chemical & Metallurgical Engineering

SIR:—The article under the above caption in your issue of Feb. 15 is likely to give rise to false impressions in the paragraph on stucco. This would give the idea that lime was added purposely to sorel cement, whereas it is an absolutely undesirable impurity and usually results in the quick disintegration of the sorel cement containing it.

This is recognized in the article by Messrs. Seaton, Hill and Stewart in your issue of Aug. 17, 1921, where they give the following tables:

TABLE I—EFFECT OF LIME CONTENT, AS DETERMINED BY ADDITION OF LIME

No. Lime added	Tensile Strength, Lb. per Sq.In. 3.70%	2.69%	1.68%	0.67%
1	329	364	486	826
2	328	320	470	653

TABLE II—EFFECT OF ADDITION OF $Ca(OH)_2$ TO CALCINED MAGNESITE

1 part magnesite, 2 silex, 5 sand, by weight, 22 deg. Bé. $MgCl_2$

Per Cent Ca $(OH)_2$	Tensile Strength Lb. per Sq.In. 7 Days	30 Days
0	490	882
1	397	562
3	347	473
6	150	247
10	207	230

and as noted in the same article was earlier discussed by Rourke.

In percentages a little greater than those tested by Mr. Seaton—that is, from 5 to 10 per cent of active CaO—I have had entire test briquets disintegrate into pieces not one of which would be more than ¼ in. along the edge. In smaller percentages the test briquets would swell and twist without actual disintegration and would become moist and soft in damp weather, even after standing 6 months.

Similar bad effects are caused by the use of excessive amounts of calcium chloride in the magnesium chloride solution with which sorel cement is set, or by the presence of large amounts of calcium chloride in the dry powder for water mix stucco. DONALD M. LIDDELL.

New York City.

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to the points brought out in Donald M. Liddell's letter on the article "An Outline of the Uses of Lime," I wish to state that the use for lime which we had in mind in connection with the manufacture of sorel cement was not the addition of lime to the cement but the use of a dolomitic lime as the base for the cement. This is a subject which has received a great deal of investigation in many places and was the subject of a paper read by J. B. Shaw at the spring meeting of the American Ceramic Society in 1921. The subject of this paper was "New Developments in Oxychloride Stucco and Flooring." The process described consists of burning dolomitic lime at a temperature at which the calcium carbonate is not decomposed. The product is then treated with alkaline earth chloride solutions.

I believe it is generally agreed that the addition of lime to sorel cement, as ordinarily made, is not advisable. M. E. HOLMES,

Washington, D. C. Manager, Chemical Department, National Lime Association.

Cost of Analyses in State Laboratory

To the Editor of Chemical & Metallurgical Engineering

SIR:—The statement on page 521 of your March 15 issue showing the cost of chemical analyses made by the State Department of Chemistry, Harrisburg, Pa., is truly a most interesting one. If we analyze this statement we find that 2,876 complete analyses of a variety of materials are handled at a cost of $13,689.76, which expense covers overhead, rent, light, etc. This is an average of 9 samples per day, and if we assume 5 determinations per day at a total cost of approximately 90 cents per determination, as compared with a charge of $4 per determination made by the commercial chemist.

In view of the fact that it is our earnest endeavor to produce dependable analyses by well-trained and well-paid chemists, at the lowest possible price to our customers, we are at a loss to understand why we (the commercial chemists as a class) are compelled to charge four times the price for the same class of work as J. W. Kellogg, inferring that he is applying the same labor and overhead expenses which the commercial analysts must bear. If possible, we should like to pass on to our clients in the form of lower prices benefits of any information as to reducing expenses. At the same time it must be understood that we are not eleemosynary institutions and that a small profit at least must be allowed us.

We surely hope that more detailed statement as to the activities of the Pennsylvania State Department of Chemistry would not prove as disappointing to us as the reported profits covering the operations of the Emergency Fleet Corporation.

NEW YORK TESTING LABORATORIES,

New York City. L. R. SEIDELL.

A New Point of View

To the Editor of Chemical & Metallurgical Engineering

SIR:—Having just read the Dec. 14, 1921, issue of your journal, I am very much astonished at the tone of the article headed "Haber, Nernst and the Amenities of Life." This article is in fact an insult against the eminent men who are members of the Svenska Akademien, an institution whose position above the hatred between nations which resulted from the war absolutely cannot be questioned. If the Svenska Akademien has seen fit to grant the Nobel prize to the great inventers Haber and Nernst, you can be assured that this has been done, not because their inventions have been used partly in chemical warfare, but because these inventions have served and will further serve mankind in the work for progress.

Your journal is remarkable for its often repeated hateful articles against Germany. When Germany was forced into the great war by aggressive Russia, I cannot understand why the Germans should not have the right to fight! But the Germans were far ahead of you in applied chemistry in all its branches, and that is possibly the cause for your campaign against them at all suitable and unsuitable times. I remember that some months ago you published an article against Germany, because that country made an attempt to apprehend the three chemical engineers (and only partly succeeded in it) who had been bought for money by the Americans to steal the secrets about some dye products of value to you and to cross over the sea with these papers or samples. I am sure, for myself, that it had been better for you not to mention that dirty affair at all. If you are such masters in chemistry, why did you engage the men to betray their country and their firm?

Domnarfvet, Sweden. HAROLD ALMQVIST.

It should be needless to add that our comment was in no sense intended as "an insult against the eminent gentlemen who are members of the Svenska Akademien." Our correspondent offers a novel and hitherto unpublished explanation of the cause of the late war. Evidently much depends upon the point of view.—EDITOR.

The Composition of Pine Oil

To the Editor of Chemical & Metallurgical Engineering

SIR:—In connection with the discussion between L. F. Hawley and C. M. Sherwood regarding the composition of pine oil, the accompanying chart may be of interest. This chart has been compiled from a study of the literature, including Schimmel & Co.'s semi-annual reports and the Forest Service bulletins, as well as the chemical periodicals. In this chart we have listed all the compounds we could find reported as found in oils obtained by steaming pine wood.

A consideration of the structural formulas of these compounds suggests that the terpineol might be derived from the dipentene by addition of water, and that the dipentene was an intermediate step between the alpha-pinene and the terpineol. Similarly the nopinene might conceivably rearrange to gamma-terpinene and the addition of water to the latter give rise to the cineol.

We should be very glad to have your readers' criticisms of this chart, as we feel that the subject is worth considerable study and discussion.

JOSEPH H. WALLACE & CO.
By R. H. Stevens, Chemist.

Stamford, Conn.

Italian Chemical Industries

From Our Special Correspondent

Genoa, Italy, March 8, 1922.

During the last 5 weeks the different branches of the Italian chemical industry have been affected by the following economic factors: (1) The continued scarcity of electric power, which has been only in part compensated by the use of oil and gas engines and steam motive equipment. (2) The continued rise in the value of the Italian lira, which has caused considerable loss among the different producers and merchants, especially those who are dependent upon foreign raw materials. (3) The rise in the price of coal. (4) The diminishing demand for chemical products, due to financial difficulties and the smaller purchasing power of the consumers. And (5) the imminent danger of a strike in the principal chemical factories. Most of the works in the tartaric acid, citric acid, dye and heavy chemical industries have refused to continue the present wage scales, such as were arranged during last November. The strike will not be general, however, since the owners of the india rubber factories, the fertilizer works and the match plants have decided to continue their present policies as regards wages.

Sulphur Industry

During February there was a continuation of the campaign for a reorganization of the sulphur-mining industry in Sicily. It is hoped that the purchase of new mechanical equipment will serve to relieve the difficulty caused by the very crude methods of mining, as well as the lack of adequate transportation facilities. Some improvement in the industry has been noted since the organization of the Anglo-Sicilian Co.; however, this company took possession of only one-third of the sulphur mines in Sicily, and in the remaining two-thirds conditions remain practically unchanged. In 1916 the sulphur industry employed 11,732 workers and the output reached 1,672,571 tons of sulphur. In 1917, using practically the same equipment and employing 11,688 miners, production decreased considerably. Recently the prices for the different sulphur products have fallen to new low levels due primarily to the small demand and to the large stock which had been accumulated by the producers.

Tartaric Acid Industry

During the month the Italian Chamber of Deputies discussed the advisability of increasing the export taxes on raw materials, in order to raise the price of tartaric acid to that of the various foreign manufacturers. This arrangement would, of course, benefit the few Italian producers of tartaric acid and cream of tartar. However, the proposition was seriously opposed by the exporters of raw tartar and by the wine producers, and it is scarcely believed that any increase in the export duty will be effected.

Sugar Industry

The Italian sugar industry normally employs about 5,000 operatives in its thirty-eight sugar works. During the season in which the beets are harvested, which usually lasts from 60 to 80 days, 15,000 additional peasants are employed. The capital invested at present amounts to about 374,000,000 lire, and the annual production of sugar, when all the plants are operating at full capacity, is about 300,000 tons. During the past year, however, only about 205,000 tons was produced, notwithstanding the fact that the country consumed 250,000 tons. The reason for this is that only 74,000 hectares was cultivated for beets during the past year. There are nine sugar refineries in Italy, two of which are independent, while the others are controlled by the beet growers. Although at present there is a manufacturing tax of 2,161.50 lire per ton, and also a duty of 360 lire gold, it is possible to import foreign sugar at a price approximately equal to that of the product manufactured in Italy. It has recently been stated that a number of sugar works will be compelled to remain closed, if the government does not make some change in the present customs treatment of sugar.

Petroleum Industry

The dearth of water power has stimulated the search for petroleum in the different parts of the Italian Kingdom. It is reported that new deposits have been discovered in the Emilia region and that large resources were disclosed at San Giovanni Incarico, at Pico, in the Liri Valley. It is further stated that considerable resources are known to exist on the isle of Sicily.

Fertilizers

The rise in the value of the Italian lira and the small demand on the part of consumers have resulted in considerably lower prices for fertilizers. The season is already well advanced, and the stocks, especially those of nitrate of soda, are quite large and further cargoes are expected to arrive. For this reason additional reduction in the price of fertilizers is already foreseen. Sulphate of ammonia continues in good demand and it is stated that it is practically impossible to fill all of the orders. Germany continued to prohibit the exportation of sulphate of ammonia and all that could be secured came from either the United States or England. Ammonium nitrate could have been sold to good advantage, but very little was offered. The situation in regard to superphosphates remains unchanged. Imports of rock phosphate during last October reached 42,537 tons, as compared with 23,865 tons during the same month of the preceding year. During November the imports were only 21,834 tons, as against 25,983 tons in November, 1920.

Metal Imports

The Italian imports of metals during September reached 832 tons, during October 644 tons, and during November 5,434 tons. These, however, are considerably less than the imports in the corresponding months of 1920, when 11,512 tons was reported for September, 3,399 tons for October and 7,320 tons for November.

Swiss Demand for Copper Sulphate

Considerable quantities of blue vitriol are required in Switzerland for the spraying of the vines. Imports fluctuate between one and three million kilograms a year. In 1919 Great Britain supplied Switzerland with copper vitriol valued at 1,000,000 francs, or two-thirds of the total supply, but in 1920-21 Germany was the chief supplier. At the present time copper vitriol is a state monopoly in Switzerland. Free imports, however, would make the vitriol about 2,000 francs cheaper per truck, so that the abolition of the monopoly is demanded. It is probable that the monopoly will be abolished very soon.

COPPER MINE AT CHUQUICAMATA, CHILE

Minerals, Earths and Clays of Latin America—I

The First of a Series of Three Articles Describing the Mineral Resources of Latin America and Analyzing the Economic Factors on Which Their Development Is Dependent—Chilean Nitrates, Tin, Copper, Iron, Gold and Silver Are Discussed*

By OTTO WILSON
Former Chief, Latin-American Division, Department of Commerce

FROM the earliest years of exploration the countries of Latin America have been associated with the production of mineral wealth. It was partly in search of precious metals that Columbus and his successors set sail, and after such metals were found a continuous stream of them flowed across the Atlantic for 300 years. Their production meant slavery and death for great numbers of Indians, but at the same time it furnished the chief impetus to the settling of the territories south of the Rio Grande. Gold and silver are still mined to the extent of many millions of dollars annually, and silver, because of the Mexican output, continues to be one of the leading Latin-American minerals. But both are now recovered to a very considerable extent as byproducts in the mining of other metals, and in the last 30 or 40 years other minerals have passed them in total value of output.

The World War was particularly effective in stimulating the production of the so-called base metals, and the high prices during the war and immediately thereafter acted as an "open sesame" not only to many abandoned workings but also to entirely new sources of supply. The more recent fall of prices in turn relegated most of these new workings again to the wilderness, but they may be considered as an important part of the world's known reserve, to be drafted into service again whenever a special need arises or whenever the demand shall be sufficient to meet the costs of mining and transportation. These costs, so far as great areas are concerned, are prohibitive in normal times and will probably continue so largely because the mountainous mineral country is still so sparsely settled.

Dearth of Transportation Facilities

Of the three great mineral regions into which Latin America may be roughly divided—(1) Mexico and Central America, (2) the Andean and neighboring highlands, and (3) the rich Brazilian field centering in Minas Geraes—only the first can be said to be even fairly well provided with railways. Furthermore this is true only of parts of Mexico and is not at all true of Central America. The second region, extending along the entire western coast of South America, possesses the advantage of being near the seaboard, but this is partly offset in Colombia, Ecuador, Peru and Bolivia by the fact that the mines are found in the highest mountain country in either of the Americas, sometimes 10,000 to 15,000 ft. above the sea. This plateau region has been penetrated by only a few railways—viz., one leading up from Guayaquil to Quito in Ecuador, two or three others in Peru, and finally the two in northern Chile which furnish an outlet to Bolivia. Many of the rich Chilean mines lie in or near the lower coast ranges, and they are the most accessible of all South American mines, but even here the desert nature of the country

*The photographs for this series of articles were furnished by the Pan-American Union, Washington, D. C. For ore analyses, many figures of production and other detailed information the writer is indebted to "Mineral Deposits of South America," by Miller and Singewald, and to "Political and Commercial Geography," edited by J. E. Spurr. Both volumes are published by the McGraw-Hill Book Co., Inc.

and the lack of harbors have made their exploitation unusually difficult. The central section of the third region, the Brazilian State of Minas Geraes, is tapped by a single railway, whose grades and equipment are such that it can take care of only limited amounts of heavy ore. Throughout all of Latin America the great handicap, aside from a lack of railroads, is an almost universal absence of roads and highways. Mining machinery and supplies can be taken in and ore brought out only at great expense except in the few localities reached by the railways. Inadequate transportation thus prevents the working of many high-grade deposits, and as with other lines of South and Central American development, the exploitation of the mineral wealth must await the railway and modern means of transportation.

In point of total value the chief minerals which Latin America contributes to the world's markets are Chilean nitrates, copper, petroleum, silver and tin. The present review is interested not so much in these well-known products as in the minerals which have not yet been widely exploited, although some account of the present situation with respect to those named will be in order except in the case of petroleum, which will be covered in a later article.

The Chilean Nitrate Industry

Of all the varied products of the earth which Latin America yields, the one which constitutes the greatest source of wealth is in many respects the most curious. The nitrates of Chile form the only large deposit of such material in the world. They are invaluable both in peace and in war, furnishing a necessary constituent of fertilizers for peace-time agriculture and an equally essential constituent of explosives. In Chile this tremendous source of national wealth lies near the surface of the ground as a stratum of a barren, treeless and almost

FIG. 8—OPEN COPPER ORE WORKINGS AT COROCORO, BOLIVIA

rainless desert, extending for about 500 miles over the northern end of the country. The layer of nitrate varies from a few inches in thickness up to 12 ft., the average being perhaps 2 ft. · It is loosened by blasting, and is prepared for shipment at local officinas or factories, of which there are about 175. Extraction usually takes about 20 to 24 hours, and the amount of nitrate actually recovered has in the past been only about 70 per cent, although more economical processes are now being introduced. The cost of producing and shipping a ton of nitrate in normal times, when the price runs about $44 at a North Sea port, has been estimated as follows: Production cost, $13.10; export duty, $11.92; transportation, $4.17; commercial expense and profit, $14.88. Exporting has been going on for a hundred years and has now reached a level of 3,000,000 tons a year, valued at a round $150,000,000. The life of the fields depends partly on how low a grade of nitrate may be worked, but estimates of 200 years are held to be conservative.

At the beginning of the war in Europe the Chilean nitrate industry was stagnant, and scarcely recovered during the succeeding year. But the war demand for nitrates for explosives and the clearing of the seas of German raiders brought the industry back to its former prosperity, and in 1918 exports, standing at 3,289,325 tons, were above normal. Since then the history of the industry has been one of ups and downs. In 1919 there was another heavy slump, followed by a great gain in 1920, but again by a severe depression in 1921. The supplies in Europe are controlled by an organization known as the Pool, and the Chilean exportation is almost wholly in the hands of a producers' association. On Oct. 27, 1921, an agreement between these organizations was reached by which prices are fixed until July, 1922, and this is expected to stimulate exports and relieve the depression. Early in March, however, it was reported that conditions in Chile during the first 2 months of the year were still quiet, awaiting an improvement in the movement of nitrates. Exports in 1921 were 1,100,000 metric tons, as compared with 2,750,000 metric tons in 1920.

Copper Mining and Its Latent Possibilities

This same region of northern Chile is the site of another mining industry which in value of output may in a few years surpass even the nitrate fields. Many years ago Chile led the world in copper production. She dropped back, but in the last 5 or 6 years she has advanced again to a position second only to the United States. Her enormous reserves make it possible that she will yet pass this country and again become the leading source of the world's copper. American capital amounting to tens of millions of dollars is being invested in development works, mostly by three companies, the Chile Copper Co., the Braden Copper Co. and the Andes Copper Co. The first-named has at Chuquicamata the largest known copper deposit in the world, its positive and probable ore, with the percentage of copper, being as follows at the beginning of 1921:

	Short Tons	Per Cent
Oxidized ore	329,306,106	1.91
Mixed ore	151,000,000	2.98
Sulphide ore	210,000,000	1.84

In the latter part of 1921 the monthly production was about 4,000,000 lb. of copper, about half the 1918 average.

Throughout northern Chile there are hundreds of small mines, many of them containing ores of high copper percentage. Some have been slightly worked and abandoned because of the heavy cost of transportation, and there appears to be a good opportunity for developing these mines if sufficient capital can be invested to meet this difficulty. The ore is mainly sulphide and oxidized ore, with some native copper. Other Latin-American countries producing copper are Mexico, Peru, Bolivia, Venezuela, Argentina and Cuba. Mexico has copper in nearly every state, but the output has been kept at a minimum by the disturbed state of the country. The biggest present mines are in Sonora and Lower California. The copper production of Mexico in recent years has been as follows: 1917, 50,986 metric tons; 1918, 70,223 metric tons; 1919, 56,172 metric tons; 1920, 46,057 metric tons.

FIG. 9—SILVER MINES AT ORURO, BOLIVIA
These mines have been producers since the days of the Spanish Conquest.

In Peru two companies, both of which are now under American control, have for many years been mining copper in the high Andes and apparently have rich reserves for future working. The larger of these companies, the Cerro de Pasco Copper Corporation, had a monthly production of copper of 63,128,000 lb. in 1920, as compared with 58,124,000 lb. in 1919, 81,906,000 lb. in 1918, and 72,675,000 lb. in 1917. Bolivia has only one copper-producing section, at Coro Coro, in the central part of the country and at an altitude of 12,000 ft., where a French company mines and concentrates normally about 4,000 tons a year. In recent years, however, exportation has been much above the average, copper ore

FIG. 10—ORURO, BOLIVIA, SEEN FROM THE MINES ABOVE THE CITY

to the amount of 23,000 tons, valued at over $2,000,000, being exported in 1919. Venezuela has many copper deposits in the northern mountains, but the mining property of Aroa, worked intermittently for centuries and now owned by an English company, is the only one that has been extensively developed. The ore mined for a long while has been sulphide.

In recent years a few other copper mines have been opened, but production has been small. The copper reserves of Cuba are said to be small, but the island has recently been shipping $4,000,000 to $5,000,000 worth of ore and concentrates to the United States annually. These are the products of two mines, one near Santiago and the other in Pinar del Rio. The island of Haiti and at least one Central American country, Nicaragua, have undeveloped copper deposits. Argentina ships a few hundred tons of blister copper each year from an English-owned mine and smelter in the western Andean region, in which are several important copper-bearing localities. The ore is found in veins and much of it contains high percentages of gold and silver. Uruguay has active copper mines and undeveloped deposits.

Gold and Silver of Declining Importance Because of High Costs

Gold and silver were of course the lodestones that attracted Europeans for centuries, but gold is now of secondary importance and silver keeps its position only because of the Mexican output. This, however, is not because the deposits are worked out, but because the costs of mining and transportation are too high as compared with corresponding costs in other parts of the world. Gold is found in nearly every Latin-American country, but its leading producer is Mexico, where it is obtained to a large extent as a byproduct in the mining of copper, silver, lead and zinc. Production amounts to about $12,000,000 worth yearly, the figures for recent years being as follows: 1917, 23,542 kilos; 1918, 25,313 kilos; 1919, 23,586 kilos; 1920, 23,370 kilos.

South America now furnishes only about 2.5 per cent of the world's gold supply, the chief producer being Colombia, with $4,000,000 to $6,000,000 a year. Colombia is followed by Brazil, whose $3,000,000 annual output is supplied largely by two English-owned mines, both of which have been worked for about a century. One of these long ranked as the deepest mine in the world. Peru, Chile, Bolivia and the Guianas each produce from $200,000 to over $1,250,000 worth of gold a year. The Central American countries contribute about $3,000,000, so that the gold mines of South and Central America together may be said to produce about $15,000,000 to $18,000,000 a year.

The recent troubled times in Mexico have served to cut her normal production of silver in half. Formerly she turned out 70,000,000 to 80,000,000 oz. a year, one-third of the world's total, but in 1915 she dropped to 40,000,000 oz. and has gone lower since. In the last 3 or 4 years there has been a considerable gain, as the following figures of production show: 1917, 42,019,000 oz.; 1918, 62,517,000 oz.; 1919, 65,904,000 oz.; 1920 (preliminary), 63,600,000 oz. Bolivia, the great silver center of colonial times, still produces some silver, but is far surpassed by Peru with about 10,000,000 oz. a year. In both countries most of the metal is obtained as a byproduct, in the former of tin and in the latter of copper. Chile has had some very rich silver mines and in her whole history has produced over $300,000,000 worth of the metal, but the annual output is now less than $500,000. Colombia has been mining silver for centuries and Central America adds over 2,500,000 oz. a year to the world's total.

Tin in Bolivia

Tin in Latin America is a one-country product, Bolivia being second only to the Federated Malay States in world production. From 21,000 to 28,000 tons (tin content) is the annual output, the ore being concentrated to about 60 or 65 per cent for exportation.[1] There is a little local smelting. The value of the tin exports reached $50,000,000 in 1918. Mexico has some stream tin, and produced 9 metric tons in 1917, 13.5 tons in 1918 and 1.5 tons in 1919, but none in 1920. It is recently reported that several tons of high-grade tin ore have been discovered near Sao Paulo, Brazil, but there are no details concerning it.

These are the most valuable of Latin America's minerals as far as past and present production goes. But the list of substances of secondary commercial importance which this section of the earth holds in reserve includes nearly all the minerals known to commerce, and among them are one or two which promise to take a place of foremost importance to the civilized world.

A Steel Industry Lacking Only Coal

In that valuable group of minerals around which the iron and steel industry centers, Latin-American coun-

[1] A trade report issued by the English company J. Blum gives the 1921 shipments of Bolivian tin from the west coast ports as 17,698 tons "fine," in 60 per cent concentrates.

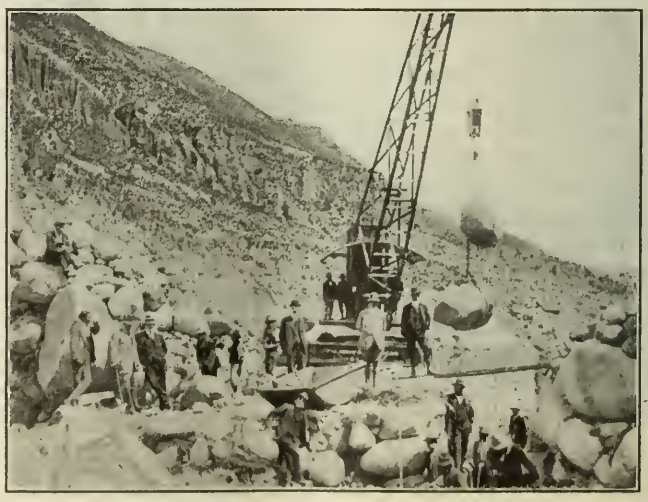

FIG. 11—GOLD MINING ALONG THE RIO CHUQUIAGUILLO IN BOLIVIA

tries are particularly rich. Yet in endowing them with this wealth Nature seems to have been in a rarely capricious mood. She has supplied immense stores of high-grade iron, and has thrown in the alloy metals, manganese, chromium, nickel, tungsten, vanadium, molybdenum, cobalt, titanium, zirconium, most of them in plentiful measure. But the one material which in the great steel-producing countries has been considered indispensable—namely, a good supply of coking coal—Nature has withheld entirely or has hidden away in mountainous regions so difficult of access as to remove the possibility of using the small deposits for iron smelting or steel making. There are coal deposits in southern Brazil which can be used for industrial purposes when mixed with imported coal, Chile has extensive beds of coal, and Venezuela has deposits of unknown extent, but this is nearly all lignite and is too soft and friable for coking. Colombia, it is estimated, has billions of tons of coal, some of which is hard coal, and Peru is said to have several million tons of anthracite; but in the case of the former country the difficulties of transportation are such that the deposits can serve only local uses, and in Peru the cost of mining and hauling is so great that that country imports much more than it produces. Only in Mexico can domestic supplies of both coal and iron be utilized to establish an iron industry, a good beginning of which has already been made.

The great iron fields of South America, in Brazil and Chile, may some day serve as a basis for a big steel industry, but if so it will probably be through the use of imported coke, brought back perhaps in the vessels that carry iron ore to foreign countries, or through the utilization of the water power which each of these countries has in abundance. In Chile the only serious attempt to establish a steel plant, using wood from the southern forests for fuel and carbon, ended in financial loss. In Brazil several attempts have been made, with the cordial support of the government, to establish plants for the production of steel with the aid of electricity derived from hydro-electric installations, but the cost has been found to be high. The latest enterprise of this character is one promoted by Brazilian interests, who are now erecting at Ribeirao Preto, in the State of Sao Paulo, two pig-iron furnaces, with a daily capacity of 60 tons, two bessemer converters, an electric refining furnace and two bar mills. The company expects to be producing steel by September. If this venture should prove continuously successful it would open the way to the building of other mills both for satisfying local demands and for exporting.[2]

FIG. 12—BAGGING TIN ORE FOR SHIPMENT, POTOSI, BOLIVIA

The iron countries of Latin America are Brazil, Cuba, Chile, Mexico and Venezuela, with deposits of apparently little economic importance in Argentina, Uruguay, Peru and Colombia. Brazil is the most important of all, and its fields may develop into the leading producing fields of the world, as geologists recognize the main deposits as constituting the world's greatest known iron reserve. The country is indeed a reservoir of iron, as ore has been reported from practically every state; but the section that holds the great deposits is a region about 100 miles square lying in the State of Minas Geraes about

FIG. 13.—OUTCROPPING BEDS OF IRON ORE, MINAS GERAES, BRAZIL

300 miles north of Rio de Janeiro. Estimates of the amount of ore in these deposits have ranged as high as 12,000,000,000 tons, but a more conservative estimate by E. C. Harder, of the United States Geological Survey, who has made a careful study of the region, is that there are 410,000,000 tons of bessemer ores with over 68 per cent iron and less than 0.02 per cent phosphorus, and about 3,000,000,000 tons of non-bessemer ore with over 50 per cent iron and 0.05 to 0.3 per cent phosphorus. This is for the main field alone and does not include many other deposits in Minas Geraes and other states which are known to be extensive, not to mention the possibilities of unexplored territory from which iron has been reported.

The ores of central Minas Geraes are hematites, and are contained in what is known as the Itabira iron formation, the material of which is a mixture largely of fine quartz sand and iron oxide. This material, "itabirite," is itself almost an iron ore, as it contains over 30 per cent iron. The best ores are a hard massive specular hematite which is found mostly in hills and which can be mined to the extent of millions of tons with almost no waste. (See Fig. 13.) Analyses by Harder show 69.65 per cent iron, 0.0125 per cent phosphorus and 0.24 per cent silica. The soft ore contains somewhat less iron and more silica. Between the hills and on their

[2] A good résumé of the various enterprises projected for the establishment of an iron and steel industry in Brazil will be found in a pamphlet just issued by the U. S. Department of Commerce as Trade Information Bulletin 6, "The Brazilian Iron and Steel Industry."

lower slopes is often found a layer of lower grade ore known as "canga," commonly less than 10 ft. thick and containing in the better grades 50 to 60 per cent iron and 0.1 to 0.3 per cent phosphorus, of which it is estimated there are about 2,000,000,000 tons.

This region is served at present by only one railway, which runs to Rio de Janeiro and is equipped to handle only limited amounts of ore. The logical port for this field is Victoria, and its development will probably be slow until it is connected by railway with that city. This can be effected by the construction of a branch to an existing line, the Victoria-Minas Railway, and a contract for the construction of this branch, and also another branch from the same line to the port of Santa Cruz, was signed in 1920 by officials of the government and by the Itabira Iron Ore Co., Ltd., which controls large ore deposits. The iron properties are owned by a considerable number of companies, mostly Brazilian, American and English. Hematite ores are found also in western Minas Geraes, in Bahia, in Goyaz and near the inland river port of Corumbá, in the far interior. Magnetite ores are also found, the best known deposits being in the State of Sao Paulo and containing, according to analysis, 64 to 71.3 per cent iron and 0.031 to 0.041 per cent phosphorus.

Chilean and Cuban Iron Ores

The only iron ores which the continent has supplied to external commerce to any great extent have come from Chile, where the Bethlehem Steel Co. has constructed extensive works, including a harbor blasted out of the solid rock. The Tofo deposits, which that company is working, comprise an estimated 100,000,000 tons of ore, mostly hematite, which analyzes 67.5 per cent iron, 0.2 per cent manganese, 0.011 to 0.05 per cent phosphorus, 0.01 per cent sulphur, 2.5 per cent silica and 0.8 per cent titanic oxide. It is said that when all improvements are completed the company will be able to ship in the neighborhood of 1,000,000 tons of ore a year. Chile has many other scattered deposits of both magnetite and hematite.

Cuba ranks as one of the great iron countries of the world, with deposits estimated at 3,000,000,000 tons of brown hematite on the north coast and minor deposits of several million tons of magnetite and hematite on the south coast. The former ore as mined is soft and wet, and it runs, when dry, about 46 per cent iron, 0.01 per cent phosphorus, and 1.7 per cent chromium. The Bethlehem Steel Co. is the principal owner. The iron deposits of Mexico are scattered over several states. The country manufactures pig iron, the largest plant, located at Durango, producing 50,000 to 100,000 tons yearly. Venezuela has several deposits of iron, but only one has been worked. This is the Imataca deposit, near the Orinoco River, about 75 miles from its mouth. The ore is a mixed magnetite and hematite and analyzes about 66 per cent iron, 0.031 per cent phosphorus, 0.045 per cent sulphur and 0.139 per cent titanium. Argentina smelts a small amount of iron ore yearly and Paraguay is reported to have abundant ore, including magnetite, hematite and limonite, and running as high as 50 per cent iron. There is a plant at Ibicuy for working the ore.

Part II, which discusses Latin-American resources of manganese, chromium, tungsten, vanadium, molybdenum, cobalt, titanium and zirconium, will appear in a subsequent issue.

Coke Production Statistics for 1921

The first convincing demonstration that the byproduct branch of the coking industry could maintain itself in a period of industrial depression more strongly than the beehive branch was made in 1921.

In 1921 the output of byproduct coke was almost 20,000,000 tons and that of beehive coke was about 5,500,000 tons, figures that show a striking contrast to those for 1920, when the output of byproduct coke was more than 30,000,000 tons and that of beehive coke was more than 20,000,000 tons. The output of beehive coke in 1921 was less than that in any other year since 1885. The output of byproduct coke in 1921 also showed a marked decline from that of 1920, but despite the extraordinary slump in business, which greatly lowered the output of byproduct coke, it was greater in 1921 than in any preceding year except 1917, 1918, 1919 and 1920.

TABLE I—ESTIMATED MONTHLY PRODUCTION OF BEEHIVE AND BYPRODUCT COKE AND OF PIG IRON IN THE UNITED STATES IN 1921

Month	Beehive Coke (Net Tons)	Byproduct Coke (Net Tons)	Pig Iron (Gross Tons)
Monthly average 1920	1,708,000	2,569,000	3,077,000
January, 1921	1,137,000	2,278,000	2,416,000
February	865,000	1,888,000	1,937,000
March	575,000	1,772,000	1,596,000
April	328,000	1,519,000	1,193,000
May	300,000	1,590,000	1,221,000
June	232,000	1,408,000	1,065,000
July	180,000	1,297,000	865,000
August	248,000	1,383,000	954,000
September	289,000	1,423,000	986,000
October	416,000	1,734,000	1,247,000
November	477,000	1,766,000	1,415,000
December	514,000	1,860,000	1,649,000
Total, 1921	5,561,000	19,918,000	16,544,000

TABLE II—SHOWS THE BYPRODUCT OVENS IN USE AT BEGINNING AND END OF 1921 AND UNDER CONSTRUCTION JAN. 1, 1922, BY TYPES

Type	In Existence Jan. 1, 1921	In Existence Jan. 1, 1922	Under Construction Jan. 1, 1922
Koppers	6,036	6,303	85
Semet-Solvay	2,415	2,463	..

Piette	...	8	..
Total	10,881	11,164	85

Table I shows the production, by months, of each type of coke, and the output of pig iron.[1] The fluctuations in the output of coke evidently followed closely the fluctuations in the output of pig iron.

Capacity of Byproduct Ovens

The annual production of byproduct ovens in operation on Jan. 1, 1922, would be 44,275,000 net tons of coke if the ovens continued in operation without interruption 365 days in the year. As the average yield of coke for the industry amounts to 69.9 per cent of the coal used, this output represents a coal-carbonizing capacity of 63,340,000 net tons a year. However, operation at full capacity is impossible, even in periods of good demand for coke, and the figures for operation at 85 or 90 per cent of full capacity really represent a normal maximum for any considerable period. In other words, the byproduct coke ovens operable Jan. 1, 1922, can treat only about 55,000,000 net tons of coal a year.

[1]Figures on pig iron for 1920 from American Iron and Steel Institute; those for 1921 from *Iron Age*.

Legal Notes

By Wellington Gustin

Delivery f.o.b. Construed

In an action by the Partola Manufacturing Co. against the General Chemical Co., brought to recover damages for a breach of contract in the refusal to deliver blue vitriol, a judgment on trial was rendered favorable to the defendant, but this was reversed and a new trial granted. The sale in suit was made through a broker for the General Chemical Co., selling agent for Nichols Copper Co., to the Partola Mfg. Co., consisting of 150 tons Nichols Triangle brand 98-99 per cent, large crystals, blue vitriol, standard quality. A broker's memorandum was afterward amplified by written contracts. Goods were for consumption and not for resale. Plaintiff's factory was situated at 207 East Tenth St., and the delivery demanded by it upon Nov. 10, 1917, was for delivery at that place, or, if that were not practical, to any downtown New York pier. The brokers were the selling agents for the defendant, which had its factory in Long Island City, which is within Greater New York City.

The first question presented was the effect of a provision in the contract that delivery was to be in barrels "carload lots f.o.b. New York." Since the seller's works were at Long Island City, within Greater New York, and as the goods were sold for consumption by the plaintiff, whose factory was in Manhattan, this provision for delivery f.o.b. New York is ambiguous.

Some of the experts as to custom testified that the effect of this provision in such a contract has no significance. However, the court says an f.o.b. contract is recognized as placing the cost of transportation upon the buyer, and, while Long Island City is in Greater New York, a fair interpretation of this contract calls for a transportation of the goods to Manhattan at cost of the buyer.

The contract of sale required the buyer to give shipping instructions as to carrier and transportation, and as to whether the goods should be transported by truck or by water. Plaintiff failed to ask for deliveries in October and when it demanded deliveries on Nov. 10, the defendant replied that as October had passed it was not obliged to make deliveries upon the November demand. However, in view of the ambiguity of delivery, the court said delivery either to plaintiff buyer's factory or to some dock in New York City was not sufficiently specific.

Failure to Order Delivery of Installments

On the question of failure to order delivery of one or more installments under a contract providing for delivery by installment, section 126 of the personal property laws provides: "It depends in each case on the terms of the contract and the circumstances of the case whether the breach of contract is so material as to justify the injured party in refusing to proceed further and suing for damages for breach of the entire contract, or whether the breach is severable, giving rise to a claim for compensation, but not a right to treat the whole contract as broken."

The court said, assuming that there was unreasonable delay in sending shipping instructions and making demand for the installments which might be due in October, there is nothing in the case to show that such a failure on the part of the plaintiff was sufficiently material to authorize the defendant to renounce entirely its obligations under the contract. The court points out that it was only when the price of the product had risen somewhat and the execution of the contract would have been unprofitable to the defendant that it refused to perform, and then placed its refusal upon an entirely inadequate ground. In the written contract it is provided: "Each month's shipment to be treated as a separate and independent contract, but if buyer fails to fulfill terms of order, purchase or payment under this or other contracts, seller may defer further shipments until such default is made good, and may at its option treat such default as final refusal to accept further shipments hereunder." Refusal was not based on any such provision, so judgment was reversed and new trial granted.

No Recovery for Damage to Soda Lakes by Government Project

Suits involving Little Soda Lake and Big Soda Lake, located in Churchill County, Nevada, have been decided by the United States Supreme Court favorably to the federal government. Actions to recover $35,000 and $170,000 by the John Horstmann Co. and the Natron Soda Co., respectively, against the United States were begun in the Court of Claims. From judgments dismissing the actions the claimants appealed to the Supreme Court, which has affirmed the judgments.

Little Soda Lake and surrounding land were owned by the Horstmann Co., while Big Soda Lake was owned by the Natron Soda Co. and each was manufacturing soda from the waters of the respective lakes in 1906. This controversy turns upon the condition of the lakes at that time and their condition after an irrigation project was instituted by the government, called the Truckee Carson project.

The lakes are situated in an area known as the Carson Sink Valley, and in 1906 were dry bodies and the source of soda supply to the soda companies involved.

Level of Lakes Rise, Companies' Property Destroyed

From prior to 1867 to 1906 the level of the lakes had not varied more than 2 ft. In 1906 the United States Reclamation Service, acting under the authority of acts of Congress, constructed the Truckee Carson project, consisting of dams, canals and other structures whereby through the usual means large quantities of surface waters theretofore confined to the watershed of the Truckee River were in 1906 and thereafter each year transported to the watershed of the Carson River and distributed to various lands in the Carson River Valley, such that the volume of the water in the lakes has continually increased, and the level of the lakes has risen about 19 vertical feet up to 1916, in consequence of which the value of the companies' properties has been destroyed.

The government contended there was the absence of any causal connection between its works and the injury to the properties of the soda companies. The companies fought the governmental contention and deductions, and opposed to them the difference in conditions before and after the execution of the canal project, and their reasoning seems to have the support of the methods that the world employs in the investigation of its phenomena and instances, says the court. However, assuming that

there was causal connection between the work of the government and the rise of waters in the lakes and the consequent destruction of the soda properties, the court held that it did not follow that the government was under obligation to pay therefor, as for the taking of the properties.

Appropriation of Property Implies Contract to Pay

It was contended that the appropriation of property by the government implies a contract to pay its value; and it was further declared that there need not be a physical taking, an absolute conversion of the property to the use of the public, but that if by public works the value of the property of an individual is substantially destroyed its value is taken within the scope of the Fifth Amendment.

The court says while this is a general rule, still there are exceptions. To bind the government there must be implication of contract to pay, but the circumstances may rebut that implication. That is, what is done may be in the exercise of a right and the consequences only incidental, incurring no liability.

This Case Outside the General Rule

It further announced that it would border on the extreme to say that the government intended a taking by that which no human knowledge could even predict. It was found that there is obscurity in the movement of percolating waters, and that there was no evidence to remove it in the present case, and necessarily there could not have been foresight of their destination nor purpose on the government's part to appropriate the properties. Any other conclusion would deter from useful enterprises on account of a dread of incurring unforeseen and immeasurable liability. This comment is of especial pertinence.

Mississippi Anti-Gin Act Upheld by Supreme Court

In a suit testing the constitutionality of an act of the Legislature of Mississippi called the "anti-gin act" the Supreme Court of the United States has upheld that law and affirmed judgment against the Crescent Cotton Oil Co. This act prohibits corporations from owning or operating any cotton gin, when such corporation is interested in the manufacture of cottonseed oil or cottonseed meal. A proviso permits cottonseed oil companies to operate gins of a prescribed capacity, but only in the city or town where their oil plants are located. A penalty is provided for violation of the act, but corporations are permitted to operate their gins for a reasonable time until they may be sold.

The Crescent company, organized under the Tennessee laws, owned and operated a cottonseed oil mill at Memphis, Tenn., and two cotton gins in Mississippi. It disregarded the anti-gin act, and the Supreme Court of Mississippi affirmed a judgment against it, declaring its right to do intrastate or local business in Mississippi forfeited, and perpetually enjoining it from operating cotton gins in the state, as well as ordering it to dispose of its gins operated within the state within 90 days. A penalty was also imposed.

The case was argued before the U. S. Supreme Court upon the assumption that the anti-gin act was enacted in aid of the anti-trust laws of the state, under the conviction on the part of the Legislature that it was the practice of corporations operating oil mills and cotton gins to depress the price of ginning regardless of cost, until local competition was suppressed or brought to terms, and then to charge excessive prices for ginning and to pay unfairly low prices for seed.

Company Claimed Unconstitutionality

The company relied upon the unconstitutionality of the act, which it asserted upon two grounds—namely, first, that as to the company it imposes a direct and substantial, and therefore unconstitutional, burden upon an instrumentality of interstate commerce, and second, that the act, being applicable to corporations and not to individuals owning and operating cotton gins, it denies to the company the equal protection of the laws.

The basis of the first contention was the claim that it had become impracticable for the oil company to carry on its oil-manufacturing business successfully when purchasing its cotton seed supply from other ginners or from brokers, that for this reason the company acquired its two cotton gins in Mississippi and nine in other states to obtain the advantages of purchasing seed direct from the growers of cotton, and that all the cotton seed which it had purchased in connection with gins was shipped in interstate commerce to its oil mill at Memphis, the gins being in effect "feeders" to its oil mill, and therefore essential means and instrumentality of interstate commerce.

Manufacture Is Not Commerce

But the Supreme Court says manufacture is not commerce, and though an article, when in the process of manufacture, is intended for export to another state, this circumstance does not render it an article of interstate commerce.

It is only when the ginning of cotton is completed, and the seed, if sold for shipment out of the state, has been committed to a carrier for interstate transport, that it passes from the regulatory power of the state into interstate commerce and under the federal laws and power.

Again, it is said that since manufacturing operations are not commerce, cotton gins are not instrumentalities of interstate commerce; and the anti-gin act, prohibiting the ownership or operation of any cotton gin by any corporation interested in the manufacture of cottonseed oil or meal, does not impose a direct burden on interstate commerce in violation of the United States Constitution, though the corporation operating again ships all the cotton seed purchased in connection with its gins in interstate commerce. Further, the court says, the act does not deny the equal protection of the laws to foreign corporations owning cotton gins in Mississippi, because applying only to corporations, since, where a foreign corporation has no federal right to do business in a state, and no contract right is involved, and there is no employment by the federal government, the state may impose conditions in its discretion on the right of such corporation to do business, even to the extent of excluding it altogether, and in such case the inherent difference between corporations and natural persons sustains restrictions applicable to corporations alone.

Again, any reasonable classification, not arbitrary, adopted by a state in the exercise of police power will be sustained against an attack based upon the equal protection clause of the Fourteenth Amendment, and the anti-gin act, forbidding operation of cotton gins by corporations manufacturing oil or meal, does not make a classification so without reasonable basis as to be arbitrary, because applying only to corporations.

The Manufacture of Electrolytic Iron

General Data for a Commercial Plant Manufacturing Pure Iron for Electrical Purposes—Effect of Composition, Temperature and Circulation of the Electrolyte Upon the Physical Properties of the Deposited Metal

By G. F. McMAHON

ELECTROLYTIC IRON deposited from the ammonium sulphate-chloride-ferrous sulphate bath after treatment by special processes is suitable as a substitute for certain grades of sheet iron and iron wire in various types of electrical equipment. Up to within the last few years its use on a commercial scale made slow progress, its high cost delaying investigation and manufacture perhaps more than anything else.

There is a process in Grenoble,[1] France, now in commercial use manufacturing boiler tubes from a ferrous chloride electrolyte. The Eustis process,[2] a chloride process, promises to become commercial in this country. It is the purpose of these to produce a more or less ductile deposit by exercising special control of the electrolyte temperature and current densities used. It is the purpose of the process to be described to produce a brittle deposit, also by special means, that can be pulverized. The first two processes referred to in this paragraph differ from the third in purpose as well as in technical detail.

Electrolytic iron was first made in about 1860 by Bietz[3] for the purpose of making a few magnetic tests. Shortly after that more tests were made by numerous other scientists. Boettger[4] probably was the first man to make any commercial use of the material. He deposited iron from a ferrous ammonium sulphate solution for the purpose of facing printer's type.

C. F. Burgess and Taylor[5] tested electrolytic iron for its magnetic properties after being deposited and cut into rings. They found the material hard and brittle. Dr. Burgess and Carl Hambeuchen[6] produced about 1,000 lb., for experimental purposes only, about the year 1904 by using an aqueous solution of ammonium sulphate and ferrous sulphate as the electrolyte. Previous to these investigations Stotelow[7] in 1873 tested electrolytic iron for its magnetic properties after being deposited. He used a ring of soft electrolytic iron with two coils wound around it and obtained important results on the permeability of such material.

A very good bibliography on these earlier investigations is compiled by T. Yensen,[8] who has done noteworthy work on melting and alloying in vacuo, together with subsequent testing of the metals.

If a chemical analysis were made of the electrolyte used by O. P. Watts and M. H. Li[9] in 1914 in their experiments on the "Effect of Addition Agents in Electrodepositing Iron," it would be found to be nearly the same as that used in the operation of a large plant, although different chemicals are used to start. Ammonium chloride may be used in place of ferrous chloride to obtain the desired chlorine content. Whatever the electrolyte lacks in ammonia may be made up by adding the correct proportion of ammonium sulphate; the iron content is obtained by using the correct amount of ferrous sulphate (copperas). Ammonium chloride is more desirable to use than ferrous chloride, which is sometimes hard to obtain in large quantities.

Ammonium chloride had been used previous to 1886 and is mentioned by Alexander Watt in his book on Electrodeposition published in that year. He mentions that Gore had used that material successfully together with ferrous sulphate. I have found this to hold true in the operation of small baths, but in large volumes the ammonium concentration must be increased.

General Layout

In design, an electrolytic iron refining unit can be laid out on the same general principles as a copper, zinc or lead refinery—that is, the tanks are connected electrically in series-parallel and are approximately of the same size. Wooden tanks, inside dimensions of 3 ft. wide, 10 ft. long and 4 ft. deep, are built and assembled together on piers well above the basement floor. No lining is necessary.

The electrolyte is generally neutral or very slightly acid or alkaline in reaction. Lead piping gives the best service and withstands corrosion better than wrought iron, cast iron or bronze, although any of the latter may be used for some time before showing appreciable signs of wear.

The writer has found it necessary to filter the electrolyte continuously in order to keep the impurities at a minimum. Electrolyte flows through each tank at the rate of approximately 3 gal. per minute. The overflow is collected in a launder and carried to a pump tank, where it is mixed with Filter-Cel and pumped by a special type bronze centrifugal pump through a clam-shell Sweatland filter press.

It is advisable to have more than one filter press in operation to permit cleaning of the filter leaves periodically without delaying filtration. The use of diatomaceous earths promotes the formation of a porous cake on the filter leaves. Experimentally it has been found almost impossible to filter any great length of time unless such material is used, on account of the slimy nature of the solids which tend to fill up the pores of the filter cloth.

From the filter press the clear electrolyte flows to the head tank, whence it flows by gravity into the electrolytic tanks and again to the pump tank, the flow

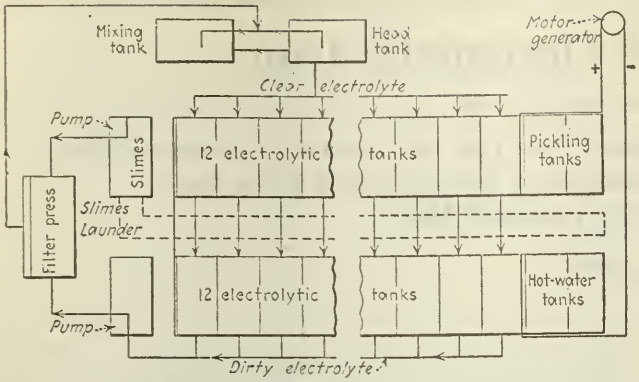

FIG. 1—SCHEMATIC LAYOUT OF ELECTROLYTIC IRON PLANT. CAPACITY 40 TONS PER MONTH

being a complete cycle. Provision is also made for the collection of anode slimes during clean-up periods and for their filtration. A traveling crane should be used, with capacity of 4 tons, for lifting sixteen electrodes at one time from a tank. Current is supplied by a 120-kw. d.c. generator, 3,300 amperes at approximately 36 volts. Pickling and hot water tanks are also installed, with the necessary steam and water lines. Fig. 1 illustrates the layout of tanks.

Anodes

Where a good grade of electrolytic iron is to be manufactured, the anode must be as pure as possible. For ordinary purposes bessemer or open-hearth steels can be used. Anodes generally used have the following approximate chemical analysis:

	Per Cent		Per Cent
Carbon	0.60	Manganese	0.30-0.50
Phosphorus	0.05	Sulphur	0.10
Silicon	0.23		

Anodes are cast to size, 3 ft. 8 in. x 3 ft. 5 in. x 2 in. thick, overall dimensions. The main body of the anode is 2 ft. 4 in. x 3 ft. 3 in. x 2 in. thick. The lugs are approximately 1 in. in thickness.

Sixteen anodes are generally used per tank on a spacing of approximately 7½ in. center to center. More anodes and cathodes can be used on closer spacing, but the current efficiency and quality of deposit are adversely affected.

Cathodes

The cathode starting sheets are made from cold-rolled steel $\frac{3}{16}$ in. thick x 2 ft. 6 in. x 3 ft. 8 in., riveted to solid hard-drawn copper bars, ½ in. x 1 in. x 41 in. long. In order to prevent the deposited iron from falling off the sheet steel blanks, which sometimes occurs, I found it advisable to drill several ¾-in. holes in the plate about 6 in. apart near the solution line. During deposition the metal nearly fills up these holes and binds the deposit to the blank sheet.

Fifteen cathodes are used per tank. The sheet steel cathode blanks before being used for deposition of the iron are pickled in dilute sulphuric acid, washed in hot water and coated with a light grade of mineral oil, preferably kerosene. Cathodes receive a 12- to 13-day deposit of iron and at the end of that time are removed, washed well in hot water and dried in an air blast. The iron deposit is then stripped, and is nearly ¼ in. thick. It has the following approximate chemical analysis:

	Per Cent		Per Cent
Carbon	0.014	Manganese	0.029
Phosphorus	0.013	Sulphur	0.003
Silicon	0.028		

It is an interesting fact that small tanks, containing 5 gal. or less, do not easily permit the formation of "trees" on the cathodes. The fact that treeing took place at an unprecedented rate during the early operation of a large unit caused the author a great deal of worry. After making slight changes in the electrolyte this undesirable condition was almost eliminated. It was found that the addition of only a trace of glue to the electrolyte rounded off the edges and sharp points, reducing the amount of treeing.

Electrolyte

The electrolyte used is composed of ammonium and ferrous salts dissolved in water. It has the following approximate chemical analysis:

Iron	60 grams per liter
Chlorine	25 grams per liter
Ammonia	25 grams per liter

The successful deposition of iron depends almost entirely upon the care used in maintaining this electrolyte.

While at first perhaps slightly acid in reaction, the electrolyte later becomes alkaline, and additions of sulphuric or hydrochloric acids in calculated amounts become necessary. Otherwise the deposit becomes full of suspended dark green ferrous hydrate. An electrolyte slightly acid in reaction produces a brittle, curly and mirror-like plate, although other conditions to be discussed later sometimes produce a similar result. If the electrolyte is neutral or very slightly alkaline, an excellent matte gray deposit is obtained which is not quite so brittle and is more adherent. The latter is the plate desired.

When cold the electrolyte is a poor conductor of electric current. It is advisable to warm the solution to about 45 deg. C. before turning on the current. An open steam jet is used. After the electrolyte becomes warm no further external heating is necessary. During summer months the temperature will rise somewhat above 45 deg. C. and unless good ventilation is resorted to the heat and humidity are oppressive to the workmen.

There is practically no loss, other than carrying-out losses, of ammonia, chlorine or iron during electrolysis. The iron, on the contrary, increases in concentration due to the addition of acids. Acid consumption is not high and does not add much to the cost of operation.

Power

A current density of between 12 and 15 amp. per sq.ft. of immersed cathode area produces satisfactory results. The actual yield of deposited iron at the above current density is approximately 90 per cent of the theoretical amount calculated according to Faraday's law; 3,300 amp. is used per tank at approximately 1.3 volts. The average output per kilowatt hour is approximately 1.5 lb. of refined iron.

Experimental Data

Unless otherwise stated, all experimental results noted in Table I were obtained at a current density of approximately 12 amp. per sq.ft. of immersed cathode area with the electrolyte at approximately room temperature, 25 to 30 deg. C.

The chemical analyses of the electrolytes are expressed in grams of Fe, NH_3 and Cl per 100 c.c. The capacity of the bath used was a little less than 10 gal.

Glue. A small amount is distinctly beneficial in the operation of large tanks, a fact which the early investigators, Watts and Li,[9] overlooked, or rather did not

perhaps have the opportunity to investigate. When other conditions are as they should be, glue forms deep solid ridges lengthwise of the cathode, which are very desirable when a solid plate, free from trees, is desired.

Stratification and Re-solution. Formation of different solution layers is caused by inefficient circulation of the electrolyte, a common occurrence in the electrolytic refining of several metals. Slow circulation is very apt to permit the acid additions to settle to the bottom of the tanks, while the top liquors become strongly alkaline in reaction. This of course affects the appearance of the cathode deposit, and an experienced operator can readily detect the condition by inspection.

Cathode re-solution is dependent on the purity of the deposited iron and on the ammonium concentration.

Ammonia. Low ammonia in the electrolyte causes the cathode to gas badly during deposition, due probably to re-solution of the iron from the resulting acid reaction, or from the decomposition of water, or both. If the ammonia concentration is not increased, the current efficiency is lowered and a rapid increase in the iron concentration of the electrolyte occurs, if acid additions are made in order to keep up the appearance of the deposit.

In large tanks the ammonium concentration of the electrolyte is therefore of great importance. Low ammonia also seems to reduce the magnetic permeability of the resulting iron, probably due to the greater amount of hydrogen in the immediate vicinity of the cathode. In small tanks no such wide variation occurs, on account of better electrolyte circulation.

TABLE I—SUMMARY OF TEST CATHODES

Grams Per 100 c.c. Fe	NH_3	Cl	Glue	Elec. Temp.	Remarks
6.00	1.30	2.50	None	Room	Good plate.
6.00	1.30	2.50	Trace	Room	Good plate.
6.00	1.30	2.50	Excess	Room	Bad plate, brittle.
6.00	1.30	2.50	Excess	Room	Bad, brittle, laminated.
6.00	1.60	0.10	None	Room	Rough plate.
6.00	1.60	0.80	None	Room	Fair plate.
6.00	1.60	1.50	None	Room	Fair plate.
6.00	1.60	2.79	None	Room	Smooth plate.
6.00	1.25	2.48	None	52 deg. C.	Good plate, soft.
6.00	1.25	2.48	None	23 deg. C.	Good plate, hard, brittle.
6.00	0.00	1.60	None	Room	Spongy.
6.00	0.40	1.60	None	Room	Slightly spongy.
6.00	0.75	1.60	None	Room	Good plate.
6.00	2.02	1.60	None	Room	Good, peeled at start.
8.00	1.60	2.75	None	Room	Rough.
3.50	1.34	2.50	None	Room	Good plate.

A high ammonia concentration improves the conductivity and increases the current efficiency, but it sometimes produces a shiny, brittle deposit similar to that from a slightly acid electrolyte. I am of the opinion that some slight impurity in the ammonium sulphate (the commercial grades do vary greatly from gas and coke-oven plants) is producing this effect, as this condition soon wears itself out and finally a good deposit is obtained. With no ammonia in the electrolyte, a soft mushy deposit of no apparent commercial value was obtained.

Sulphate. Another feature affecting the appearance of the iron deposit is a high ferrous sulphate concentration. This condition will increase the tendency of the cathode to "tree."

Chlorine. A high chlorine concentration is generally beneficial. If there is occluded chlorine or chlorides in the metal, rapid corrosion will occur on exposure to the atmosphere. Care must be exercised therefore in the control of the chlorine content of the electrolyte and in the cathode deposit.

Temperature and Hardness. The temperature of the electrolyte affects several things, the most important being the hardness and magnetic permeability of the metallic deposit. It must not be understood, however, that all variations in permeability are due to lack of temperature control. Some other causes have already been mentioned.

Iron deposited at a temperature over 50 deg C. from this electrolyte is softer than that deposited at 25 deg. C., other conditions being the same. The hydrogen content, which is quite difficult to determine, as well as the crystalline structure, may be affected by temperature of deposition. Hardness tests made on a Brinell machine, using 500 kg. pressure and a 10-mm. diameter ball, were not satisfactory, since the material was too brittle and cracked under the strain. Scleroscope hardness was 35 to over 40. A satisfactory method of determining the difference in hardness is by noting the time taken to pulverize a definite amount to a sized powder, say 80 mesh. Highly permeable soft material oftentimes takes several days to pulverize, while harder material may be easily reduced in a few hours.

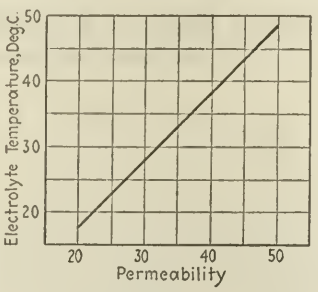

FIG. 2—EFFECT OF TEMPERATURE OF DEPOSITION ON PERMEABILITY. H = 1

Temperature and Permeability. If electrolytic iron be deposited at different temperatures under the same conditions with respect to current density and composition of the electrolyte, its magnetic permeability is almost directly proportional to the temperature of the electrolyte between the limits 25 and 50 deg. C. See Fig. 2.

The variation in the permeability of freshly prepared electrolytic iron has been known for some time and has been discussed by Terry.[10] Apparently he did not investigate the causes for such variation from the standpoint of electrodeposition, which is of importance. It has been the writer's experience that the rate of annealing and the permeability obtained is dependent largely upon the electrolytic baths and the changes occurring therein.[11]

Cement-Making Prospects in Ceylon

Some time ago several samples of clay and lime were sent from Ceylon to the Imperial Institute in London to ascertain if any of them were suitable for the manufacture of cement. It is now reported that some Jaffna clays are quite suitable for the purpose.

The commercial aspect of the manufacture of cement in Jaffna (an island separated by a very narrow channel from the northern extremity of Ceylon) is now being examined. The main difficulty, so the Ceylon correspondent of the *London Times Trade Supplement* reports, is the high price of coal. The possibility of developing a small hydro-electric scheme to operate the plant is now being studied. Experiments are also being made to find out if palmira or coconut shells could be used in place of coal.

The clays and limes of the island have not been studied systematically with a view to employing them for industrial purposes.

Introduction of Niter Into Sulphuric Acid Processes as Mixed Acid

A Description of a Successfully Operating Auxiliary Plant in Which Nitric Acid Is Made and Absorbed in Glover Tower Acid for Introduction Into the Main System

By E. L. LARISON

IN THE usual sulphuric acid plant the oxides of nitrogen are introduced into the process by potting nitrate of soda and sulphuric acid in open cast-iron pots set in the flue leading from the burners to the Glover tower.

A few plants make nitric acid in a separate apparatus and run it into the Glover tower as required. In some cases fuel-fired retorts are used, the vapors of which discharge into the gas stream entering the Glover tower. Introduction of water solution of nitrate of soda into towers or chambers is practiced to a certain extent also.

A somewhat different plan has been in use at Anaconda for the past 4 years, and it has worked out so smoothly and presents such economies that a description of it seems worth while. This scheme has also been used at Garfield and perhaps two or three other places. When the plant was installed at Anaconda it was believed to be a new departure, but since that time it has developed that one of the explosives companies tried out substantially the same arrangement for making mixed acid about 15 years ago. The scheme was not suitable, however, for the purposes of the company.

In brief, this plant consists of one or more standard nitric acid retorts, a condensing tower, a coil pipe acid cooler, a pump and the necessary tanks. Nitrate of soda and 60 deg. Bé. sulphuric acid are introduced into the retorts and heated by a coal fire to produce nitric acid vapor. This vapor is conducted into the base of a small masonry tower, over which is continuously circulated a definite charge of cool 60 deg. Bé. sulphuric acid. The nitric acid is condensed and the warm mixture of sulphuric and nitric acids issuing from the tower is passed through the cooler, pumped up and reintroduced into the tower. When the nitrate of soda has been completely decomposed, a mixed acid of definite composition has been made. This mixed acid is introduced as needed into the Glover towers of the chamber and packed cell plants.

Advantages of This Method Over Usual Practice

This arrangement presents several advantages over any of the others enumerated above. In the ordinary potting plant the vicinity of the pots is usually a mess, difficult to keep tidy and shipshape. There are, too, certain things wrong in theory about potting. The introduction of the charges is usually accompanied by an inrush of air which dilutes the gas. The evolution of the nitric acid is irregular, a fresh charge giving it off rapidly then slowing down to almost nothing. In starting up or in case of irregular running, just when it is desired to get in an abnormal amount of niter, the flue is cold and one must wait, sometimes a day or two, to establish a process, or else tap out incompletely decomposed charges. Potting must be done at rather frequent intervals. Except in very small plants, at least one man must be on duty all the time to charge and tap.

In the mixed acid scheme under discussion a clean little independent plant does the work. The nitric acid is introduced into the chamber process at an absolutely uniform rate which can be perfectly controlled. No false air is admitted. Starting up the chambers is accomplished in a few hours and irregularities in the flow of SO_2 are easily kept pace with. One man in one shift can make mixed acid corresponding to 4,000 to 5,000 lb. of niter.

The chief advantage over fuel-fired pots discharging into the flue is in the lower labor requirements. The advantages over the straight nitric acid plant lie in the simplicity and rugged character of the mixed acid plant and in the fact that this mixed acid can be handled in ordinary lead and iron pipes, pumps and tanks, just about as 60 deg. Bé. sulphuric acid can be handled.

An installation which has been in use for the past 4 years and which has given entire satisfaction is shown in plan and elevation in Figs. 1 and 2.

Retort Details and Setting

The retorts, Fig. 3, are of the usual design and are 6 ft. inside diameter and 6 ft. inside depth. They were cast at the local foundry and the metal mixture used was steel scrap 35 per cent, No. 1 pig 32.5 per cent, No. 2 pig 32.5 per cent. These retorts have a very long life, certainly more than 1,500 charges.

The construction of the brick setting is perhaps a little different from that ordinarily used. The tapping

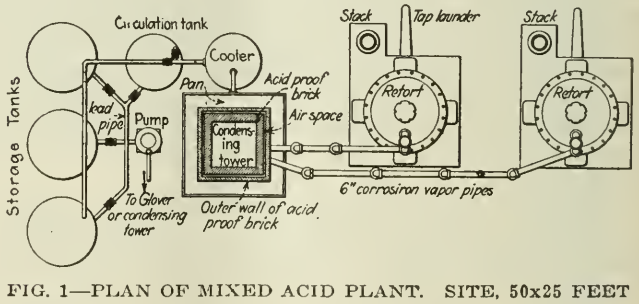

FIG. 1—PLAN OF MIXED ACID PLANT. SITE, 50x25 FEET

spout is on the opposite side from the fire and ash doors, an arrangement which is more convenient than having them on the same side. The fire gases are directed around the pots by corbeling in the walls as shown in Fig. 4. A solid 9-in. arch of firebrick covers the firebox, and the spout is protected from direct action of the flame by a small brick pier. The retort cover con-

tains the usual openings for charging and carrying away vapor, and is covered with brick.

The connections between the retorts and the condensing tower are of 6-in. Corrosiron pipe with horizontal bell joints. These pipes are apparently unaffected by 4 years service.

The Condensing Tower

The condensing tower serving these two retorts is of acid-proof brick laid in silica-silicate of soda mortar. The walls consist of 9-in. main wall with a 4-in. veneer

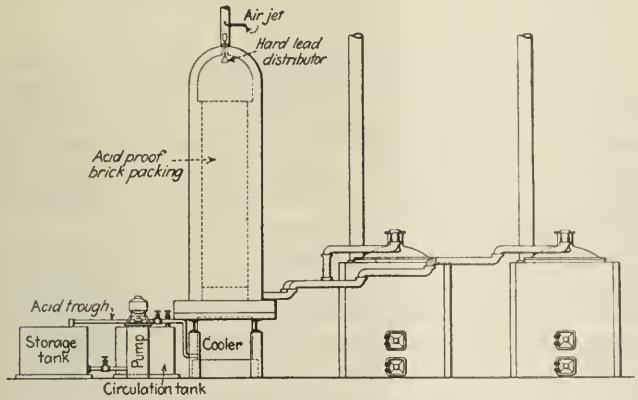

FIG. 2—ELEVATION OF MIXED ACID PLANT

course separated 2 in. from the main wall, but bonded to it in places. This construction makes the outside of the tower entirely clean and dry, as any acid which leaks through the main wall cannot cross the 2-in. space between the walls. The top of the tower is a hemispherical brick dome.

This tower is 20 ft. high and 4 x 4 ft. inside. The packing is of standard dimension acid-proof brick laid on edge and the column is 12 ft. high. The gross packed volume is therefore 192 cu.ft. The tower is built in a

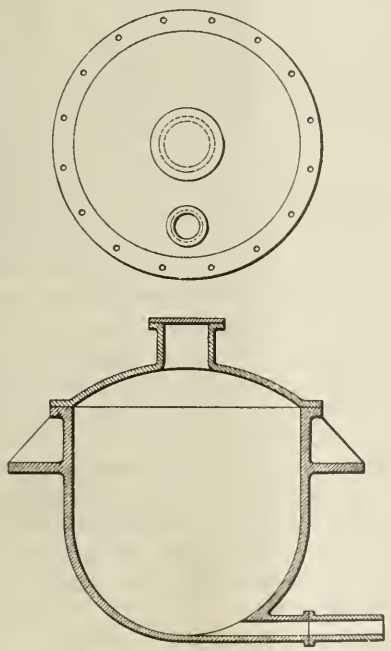

FIG. 3—TYPE OF NITRIC ACID RETORT USED

pan of 24 lb. lead with the upper part of the pan sides of Corrosiron plates. The sides of the pan are about 12 in. from the walls of the tower. This pan was originally of lead throughout, but it was found that the side walls from the acid level to the top were quickly corroded away. The lead was therefore cut down to a line a few inches below the acid level and Corrosiron plates were put in. This corrected the trouble. Beyond this no changes or repairs whatever have been necessary on this tower and it will probably require none for many years to come.

Acid is fed into the tower and distributed through a hard lead splash plate. A 6-in. Corrosiron pipe containing an air jet leads from the top of the tower to a point just above the roof. The air to this jet is so controlled as to maintain 0.25 to 0.50 in. of water suction at the retorts.

The acid issues from the tower pan into a circular lead tank 5 ft. in diameter and 3 ft. deep, containing two concentric coils of 1½-in. lead pipe through which cold water is circulated. This cooler is covered, and in operation is always full of acid. It discharges into either a circulation tank or a storage tank as desired. The tanks are connected to the boot of a cast-iron Lewis vertical centrifugal pump, which pumps to the top of the condensing tower or to the top of the Glover tower of the chamber plant. The performance of this pump has

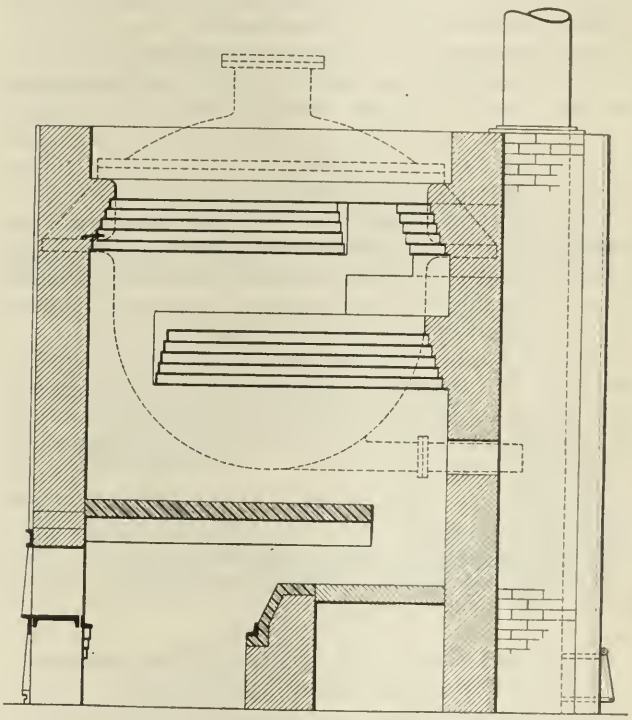

FIG. 4—RETORT SETTING

been rather remarkable. It has operated about 8 hours almost every day for over 2 years and not a cent has been expended upon it in the way of repairs.

Operation of Plant

Ordinarily the operation of this plant is conducted with the following routine. The operator comes on at 7:30 a.m. and with the help of one laborer puts 2,000 lb. of nitrate of soda into each retort, with 2,500 lb. of 60 deg. Bé. sulphuric acid. This occupies 30 to 40 minutes. The laborer is then released and the remainder of the run is conducted by one man alone.

Fire is started under the retorts and a charge of 60 deg. Bé. sulphuric acid for the condensing tower is drawn. For 4,000 lb. of nitrate of soda this acid charge amounts to 165 cu.ft., or about 8.8 tons. This acid is put into circulation over the tower, through the cooler and circulating tank and back to the pump. Once this

circulation is properly set it requires no further attention. The rate of acid flow is about 3 to 4 tons per hour.

Hourly temperatures are taken at the vapor exit of each retort and of the acid entering and leaving the condensing tower. The firing is conducted largely with these as a guide. A typical set of these temperatures is given in the following table.

TABLE I

Time	Temperature of Retort, Deg. F.	Temperature of Acid Entering Tower, Deg. F.	Temperature of Acid Leaving Tower, Deg. F.
8:00 a. m.	...	70	70
9:00 a. m.	230	70	78
10:00 a. m.	248	78	110
11:00 a. m.	256	85	122
12:00 m.	278	95	134
1:00 p. m.	290	95	150
2:00 p. m.	290	85	142
3:00 p. m.	240	82	118
3:15 p. m.	Retort tapped		

After tapping the retort the mixed acid is run to one of the storage tanks or to the tank at the top of the Glover tower. The niter cake is sampled as it runs out and the mixed acid is measured and sampled, the samples being tested in a nitrometer.

The niter cake almost invariably shows clean. The volume of mixed acid made is 220 cu.ft. It contains nitric acid and lower nitrogen oxides equivalent to 16.5 to 16.7 lb. $NaNO_3$ per cu.ft. The recovery is therefore about 96 per cent. Coal used amounts to 700 to 800 lb. per ton of niter decomposed.

The mixed acid is fed into the Glover towers through small gage boxes. Its flow is controlled by an ordinary small acid valve. The volume used is such that control is very convenient. For example, a 100-ton chamber unit will require about half a gallon per minute.

The installation described can handle up to 3,000 lb. per retort by taking an additional hour or two per run. That is, it can decompose up to 12,000 lb. of nitrate of soda per day of 24 hours, by working two 10-hour shifts or three 8-hour shifts.

The tower exit stack normally shows a very faint red. Any large air leakage into the retorts or at pipe joints is quickly indicated by more color at the stack.

The installation here described can be built for about $8,000 to $10,000.

Extraction of Corn Oil Treated in New Bulletin of Department of Agriculture

Because of the great increase in the manufacture of corn products, such as hominy, starch, glucose and sirup, the production of oil from the germ, which is removed in these various processes, has become a well-established industry. Up to the present the oil has been removed from the germs by pressure, a method that is used in this country in obtaining most kinds of vegetable oils. In European countries a good deal of vegetable oil extraction has been done with organic solvents, and recently the United States Department of Agriculture has made some trials with this method of extracting corn oil. The results have just been published in Department Bulletin 1,054, "Comparison of Corn Oils Obtained by Expeller and Benzol Extraction Methods," a professional paper by A. F. Sievers, chemical biologist.

The bulletin contains detailed comparisons of processes and of oils produced by pressure and by solvent extraction from the germ cake, a residue from the first process, and by solvent extraction from the germs themselves.

Determining Coefficient of Expansion With a Metallurgical Microscope

By Horace C. Knerr
Metallurgist, Naval Aircraft Factory, Philadelphia

THE METHOD of measuring thermal expansion herein described was developed in the course of an investigation of the physical properties of a small piece of a light alloy at the Naval Aircraft Factory. The sample, which was all that was available, was in the form of a bar approximately 3 $\frac{3}{16}$ in. long, $\frac{7}{16}$ in. wide and $\frac{5}{32}$ in. thick.

It was desired to determine as many of the properties of the material as possible, including chemical composition, specific gravity, tensile properties, hardness, resistance to corrosion, microstructure and coefficient of expansion. The expansion determination was the most difficult, but was performed with equipment available in almost any metallurgical laboratory.

As metallurgists and others may frequently have occasion to measure expansion coefficients of small samples within moderate temperature ranges without recourse to the more elaborate methods, a detailed description of this simple method may be of some service.

Method of Measurement

The determination was made with the aid of an inverted metallurgical microscope, by measuring the difference in expansion between the sample and pieces of steel and of duralumin, placed on each side, the temperature being regulated by a water bath. Observations were taken through glass windows in the bottom of the bath. Preliminary readings were taken at intervals, until a number of consecutive readings were identical, showing that the temperature of the specimen had become constant.

Accuracy

Since tensile tests had to be made on the same piece afterward, the temperature range was held to within normal atmospheric variations to insure that the physical properties of the material would not by any chance be affected. The lowest temperature conveniently obtainable in the laboratory was that of melting ice, 0 deg. C., and the total temperature range available was therefore about 40 deg. C. To determine the thermal expansion of a sample 3 in. long within a temperature range of 40 deg. C. necessitates measurements of a fairly high degree of accuracy. Take, for example, soft steel. A coefficient of linear expansion of 0.0000121 per deg. C. is given in the Smithsonian Physical Tables. Total expansion in 3 in. for 40 deg. C. is $0.0000121 \times 3 \text{ in.} \times 40° = 0.00145$ in. Likewise, duralumin (coefficient of expansion 0.0000226, according to Vickers) would expand 0.00271 in. The difference in total expansion between two 3-in. samples of steel and duralumin would be 0.00126 in., and the accuracy of the result of a method such as described above would depend upon the accuracy to which such a length could be measured.

The metallurgical microscope was provided with a micrometer eyepiece which was calibrated by means of a micrometer stage ruled to 0.1 and 0.01 mm. One division on the graduated head, using a 16-mm. objective, represented 0.0000330 in., or about 2½ per cent of the probable length (0.00126 in.) to be measured. It was possible to repeat readings to within plus or minus one

scale division. This, therefore, came well within the desired accuracy of plus or minus 5 per cent.

Preparation of the Specimen

A strip of annealed mild steel and a strip of duralumin were attached to opposite sides of the specimen, as shown in Fig. 1, the three pieces being pinned together at one end by a tight fitting pin and left free at the other end. Small spring clips were placed at the free end and at the middle, permitting longitudinal expansion or contraction of all the pieces, but preventing the strips from bowing out.

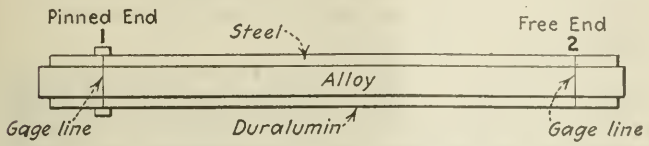

FIG. 1—ASSEMBLED BARS

The lower edges of the strips were made flush with the lower edge of the specimen, and this surface was polished smooth by emery cloth and paper laid on plate glass, finishing with No. 0000 Hubert paper.

Using the jaws of a vernier caliper for guides, gage lines were scribed upon the polished surface, one above the center line of the pin and the other 2½ in. away, both running transversely across the three strips. It was necessary to draw very fine lines, a feat which is perhaps the most difficult part of the entire experiment. A piece of microscope cover glass was shattered and a small sharp splinter selected with the aid of a magnifying glass. This was attached by means of a speck of beeswax to the end of a fairly stiff bristle about 2 in. long taken from a dust brush. This "scriber" was drawn across the polished surface of the three strips as gently as possible, using the vernier jaws as guides. These gage lines were barely visible to the naked eye, but were clear and definite under the microscope, and appeared in the image about three times as wide as the hairline of the micrometer eyepiece. It was easy to read to the center of this line. Heavier "marker lines" scribed near the gage lines facilitated determinations of direction under the microscope, which is otherwise very confusing.

The lines were ruled at room temperature, 24 deg. C. After ruling, a very thin coating of transparent varnish was applied so as to retard corrosion.

Temperature Control

A small watertight wooden box, open at the top, was constructed, as shown in Fig. 2. This was arranged to fit on the movable stage of the microscope. Holes cut in the bottom of this box were covered with microscope cover glass through which the gage lines on the specimen could be observed from below. To avoid cracking the cover glasses by unequal expansion, they were separated from the wood by means of rubber washers, the glass being attached to the rubber with Canada balsam.

For convenience, water was used as a heating and cooling medium. A 5-gal. can was placed on a high shelf above the microscope, and connected to the inlet tube of the bath with rubber hose. Overflow drained to a bucket on the floor. Flow was adjusted with a pinch-cock so as to cause a complete displacement of the liquid in the bath every 30 seconds. This insured excellent circulation about the specimen and permitted a continuous flow for about 1 hour and 20 minutes, which was ample time for the specimen to reach the temperature of the bath and for readings to be taken. The water in the 5-gal. reservoir was permitted to come to room temperature for the first set of readings, at approximately 24 deg. C. For the second readings, cracked ice was placed in the reservoir to cool the water to 0 deg. C., and for the third readings a small electric heater was arranged to warm the water to 40 deg. C. To insure uniform temperature in the reservoir, a motor-driven agitator was used.

The specimen was placed in the bath with the gage lines over the windows; it was raised slightly upon narrow strips of glass to permit circulation of water beneath it. With the water circulating, the temperature of the bath was measured with a thermometer at various places and was found uniform within about 0.2 deg. C.

Using the metallurgical microscope and micrometer eyepiece, readings were taken through the window at the pinned end of the relative positions of the gage line on the strip at both sides of the sample. The microscope stage, carrying the bath, was then moved so as to bring the other end of the specimen in position over the objective, and a reading taken of the relative position of the gage lines through the window at that end. The readings at the pinned end were for the purpose of taking care of any possible motion between the strips at this end, but it was found that none occurred.

Results

The necessary formulas and the results of the determination are given further below. Satisfactory readings were not obtained at 40 deg. C., as the water attacked the specimen very rapidly at this temperature in spite of the varnish, so that the gage lines were obliterated. The results obtained between 0 and 24 deg. C. showed the coefficient of expansion to be approximately that of magnesium. Other characteristics of the sample, determined later, disclosed that it was composed largely of magnesium.

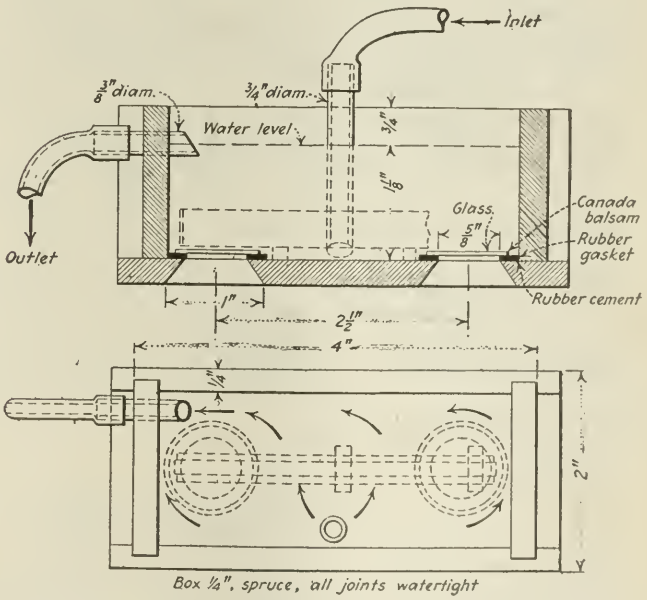

FIG. 2—THERMOSTAT FOR EXPANSION MEASUREMENTS

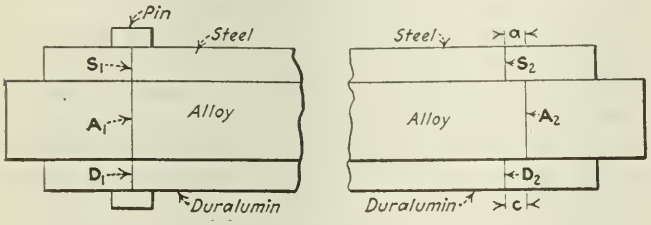
It will be noted that there was a considerable difference in the result determined by comparison with the steel strip and that determined by comparison with the duralumin strip. This inconsistency may be largely due to inaccuracy of the coefficients given for those metals

in the best available sources. There was no check upon the coefficient 0.0000226 given for duralumin from the Vickers' Bulletin, and the value 0.0000121 for steel was practically an average or approximation from several widely differing values given for steels and irons in the texts. In order to obtain accurate results by this method, it is essential to have for comparison a standard piece whose temperature coefficient is known to a



FIGS. 3 AND 4

Fig. 3 (at left)—Pinned end at normal temperature.
Fig. 4 (at right)—Free end at higher temperature.

greater accuracy than that required in the test. This is true of most methods of measurement—in fact, practically all measurements of length depend upon comparison with a previously measured standard.

As the standards of this experiment were not known to be correct, the results are of value chiefly for the sake of example.

Formulas

See Figs. 3 and 4

A movement of A_2 from S_2, to the right is plus a.
A movement of A_1 from S_1, to the right is plus b.
A movement of A_2 from D_2, to the right is plus c.
A movement of A_1 from D_1, to the right is plus d.
Difference in total expansion of alloy and steel $= a - b$.
Difference in total expansion of alloy and duralumin $= c - d$.

Let coefficient of expansion of alloy $= K_A$ (required)
coefficient of expansion of steel $= K_S$ (known)
coefficient of expansion of duralumin $= K_D$ (known)
$(T - t)$ = Temperature change
L = Gage length.

Then, total expansion of alloy $= K_A(T - t)L$
total expansion of steel $= K_S(T - t)L$
total expansion of duralumin $= K_D(T - t)L$
and $(a - b) = K_A(T - t)L - K_S(T - t)L$

therefore, $K_A = \dfrac{a - b}{(T - t)\,L} + K_S$

also, $K_A = \dfrac{c - d}{(T - t)\,L} + K_D$

Experimental Readings

Initial temperature	24.0 deg. C.
Temperature of bath	0.5 deg. C.
$T - t$	$= -$ 23.5 deg. C.

Microscope Readings
Pinned end still in line, b and $d = 0.00$
Free end,

Position of A_2	4.22
Position of S_2	4.39
$a =$	$-$ 0.17 change from steel
$=$	$-$ 0.000561 in.
Position of A_1	4.16
Position of D_2	4.22
$c =$	$-$ 0.06 change from duralumin
$=$	$-$ 0.000198 in.

$$K_A = \frac{0.000561}{23.5 \times 2.50} + 0.0000121 = 0.0000216 \text{ per deg. C.}$$

(compared with steel).

$$K_A = \frac{0.000198}{23.5 \times 2.50} + 0.0000226 = 0.0000260 \text{ per deg. C.}$$

(compared with duralumin).

Average 0.0000238 per deg. C.

This first test was hastily prepared and rather crudely performed, and the writer has not had an opportunity to repeat it with greater care. It is believed that the method has demonstrated its practicability, and improvements in detail can easily be introduced.

Some improvements which suggest themselves are:

(*a*) Use of a ruling machine or construction of a jig to facilitate the scribing of the fine gage lines. Tremors of the hand in the present method tended to cause irregular gage lines.

(*b*) Use of a light transparent oil as a heating and cooling medium, to avoid corrosion of the specimen (where this is likely to occur with water) and permit greater temperature ranges.

(*c*) Using greater ranges of temperature when possible, so as to reduce the percentage error introduced by inaccuracies in measurement.

(*d*) Use of two similar strips of a single metal or other substance of a known and preferably a low coefficient of thermal expansion as the standard of comparison. These would serve as a check against each other, and in case of warping or bending of the sample, the mean of the readings on the two sides would give the correct value. Invar would be an excellent material for this purpose.

Advantages of the Method

(*a*) The equipment is available in nearly any metallurgical laboratory.

(*b*) Results do not depend upon the accurate measurement of small changes in a relatively large quantity, but upon measuring a small *difference* between two quantities, one of which is known. A fairly accurate measurement of this small difference gives a relatively high percentage accuracy in the result.

(*c*) The determination may be made upon a small sample, the preparation of which is simple and requires no accurate machine work or grinding.

(*d*) Determinations may be made within ordinary atmospheric ranges or within any range which can be obtained with a fairly transparent liquid bath.

(*e*) The standard of comparison is subject to the same conditions of temperature, etc., as the specimen.

(*f*) The unit of length measurement (micrometer eyepiece) is entirely out of range and unaffected by variations of temperature in the heating medium.

(*g*) Displacements in various parts of the measuring apparatus do not affect the accuracy of the results.

(*h*) The length of the specimen between gage marks does not need to be measured with great accuracy. A good vernier caliper is suitable.

(*i*) The measurements are optical, avoiding the inaccuracies due to touch or to uncertain contacts, characteristic of micrometer or electric contact methods.

Japanese Experiment on Bread From Soya Bean Flour

Japanese food chemists are at work to produce a palatable bread from soya bean flour, and according to a report in the *Bulletin of the Japan Society*, tests thus far indicate that it is both palatable and digestible. It is also established that soya bean bread can be placed on the market at a price below that made from any other kind of flour. With the heavy protein content of the beans and a little butter or other fat, a ripe orange and a dish of boiled greens, it would seem that a very cheap ration—with vitamines included—was available from it. The soya bean cheese should also furnish an abundance of protein.

It is, of course, a question as to how the bread will take with the public. If it does find favor, however, it will worry the wheat grower.

Contributions to the Study of Ammonia Catalysts—IV

Discussion of the Behavior of a Type of Iron Catalyst Under Varying Conditions of Pressure, Temperature and Gas Velocity in Experiments on the Synthesis of Ammonia at the Fixed Nitrogen Research Laboratory*

By A. T. LARSON and R. S. TOUR

THE preceding articles of this series have described three types of apparatus for testing the activity of substances in catalyzing the synthesis of ammonia from nitrogen and hydrogen. The particular functions of each of these testing plants have been indicated in the separate articles. The purpose of the present article is to present data obtained by all of these methods of testing, on certain selected catalysts which have come to be regarded as typical, and to show to what extent correlation exists between the results of low, intermediate and high pressure testing, and between small and moderate scale operation.

It should be pointed out that the most important function of each of the three testing plants has been the determination of the comparative merits of a large number of catalysts rather than a logical study of the complicated phenomena involved in ammonia synthesis. Each plant has had a more or less distinct place in the general research program and has followed lines of investigation frequently differing from that adopted by the others. There are certain difficulties inherent in the problem which render almost impossible a complete identity of conditions in tests carried out upon different scales. Thus the reaction evolves a considerable amount of heat, and the heat evolution and distribution in a given volume of catalyst may vary greatly with the rate of flow of the gases and with the temperature and pressure, since these affect the reaction rate as well as the equilibrium concentration of ammonia. This means that it is inevitable that a certain temperature gradient must exist within the catalyst and although this is kept at a minimum by devices previously indicated, it is impossible to be certain that the recorded temperatures of the different testing plants operating under widely different conditions actually correspond to identical temperature conditions within the catalyst.

Again, although the catalysts are always tested upon a 1:3 nitrogen:hydrogen mixture of a high degree of purity, except when poisons are intentionally introduced, the methods employed for gas purification have not been identical and it is therefore impossible to be certain that the quality of the gas is always the same. There is reason to believe, however, that the variation in purity has been small enough to be of but minor importance and further, although the catalysts are fairly reproducible, still minor variations in activity or characteristics may appear in different batches of what is presumably the same catalyst.

It is therefore not to be expected that absolute concordance of results should have been achieved in studying substances so sensitive to conditions as contact catalysts are apt to be, nor that all results should be strictly comparable. Nevertheless, sufficient data have been obtained to warrant the statement of certain important generalizations concerning the behavior of characteristic ammonia catalysts under varying conditions of pressure, temperature, rate of flow of gases, purity of gases and other factors.

Nomenclature

Certain terms appearing in this paper are occasionally given a different meaning from that employed herein and it seems desirable, therefore, to define them.

Per Cent Ammonia. The per cent by volume of NH_3 in the gas, measured under standard conditions.

Ammonia Conversion. The *increase* in NH_3 per cent in the gas produced by catalysis.

Yield of Ammonia. The weight of ammonia produced by catalysis. When expressed in grams of NH_3 per liter of catalyst per hour, it becomes the *"space-time-yield"* ("S-T-Y").

Equilibrium or Theoretical. (Applied to per cent NH_3, conversion or yield.) This refers to the maximum theoretically possible for specified conditions of temperature, pressure, etc., assuming the correctness of Haber's measurements and calculations of the equilibrium constant for the ammonia synthesis.

Efficiency. The ratio of the actual per cent NH_3 in the gas to that theoretically possible under the conditions in question.

Space Velocity. The number of liters of gas passing over the catalyst per liter of catalyst per hour. The gas volume is measured under standard conditions regardless of the actual conditions of operation ("S.V.").

Time of Contact. The time in seconds for 1 liter of gas, measured under operating conditions, to pass over 1 liter of catalyst.

$$\text{"}t.c.\text{"} = \frac{3600}{S.V.} \times \frac{P \times 273}{T}$$

Here, P = operating pressure in atmospheres and T = absolute temperature, deg. C.

Optimum Temperature. The temperature at which (at constant pressure and space velocity) the gas after passing over a given catalyst contains the highest per cent of ammonia.

Nature of the Catalyst

The catalysts of the type selected for discussion consist essentially of metallic iron containing small amounts of a substance which influences very greatly the behavior of the iron and which is known as a "promoter." The amount of promoter in the particular catalysts used for illustration, which will be referred to as Nos. A, B, C and D, is from 2.5 to 3.5 per cent of the total weight, the remainder being metallic iron. These catalysts have been selected as a basis for discussion for various reasons. They are reasonably active, capable of

continued operation without marked deterioration, and sufficiently sensitive to poisons and overheating to permit their use in discussing these problems. Although they are not the most active catalysts which have been prepared by the Fixed Nitrogen Research Laboratory, they are nevertheless high-grade catalysts, more active than those which have usually been employed in commercial operation.

While the experimental data presented will be from the actual tests of these particular catalysts, certain generalizations will be made based upon more extensive results obtained with similar catalysts.

Preparation of Catalysts and Methods of Testing

These catalysts are first prepared as mixed oxides and are then heated in a current of nitrogen:hydrogen mixture, which reduces the iron oxide to metallic iron. The samples of catalysts employed for the small-scale apparatus, both for low- and high-pressure operation, are reduced at atmospheric pressure by placing them, usually in the form of 8 to 14 mesh granules, in a furnace and slowly heating them in a current of pure nitrogen:hydrogen mixture until reduction begins, as evidenced by the appearance of water in the outlet gas. The temperature is maintained at this point until the evolution of water ceases (usually several hours) and is then raised somewhat until water reappears. This process of heating at gradually increasing temperature is continued until practically complete reduction is effected, the final temperature being 400 to 450 deg. C.

In the moderate-scale testing plant the catalysts are prepared by reducing the oxide granules (6 to 8 mesh) *in situ* in the catalyst bomb by means of nitrogen: hydrogen mixture at 100 atmospheres pressure, with gradually increasing temperature.

After reduction the sample of catalyst is usually tested under varying conditions of temperature and space velocity, and with pure and poisoned gas.

Influence of Mesh Size of Catalyst

Since the size of the catalyst granules in the three testing plants varies from 8 to 14 mesh at the lower pressures to 6 to 8 mesh at high pressure, it is important to determine the effect of mesh size upon the catalytic activity. Tests carried out at 100 atmospheres and confirmed by data obtained at lower pressures indicate that the activity of the catalyst is independent of the size of granule, within fairly wide limits. These data are given in Table I.

TABLE I—INFLUENCE OF MESH SIZE OF CATALYST.

Catalyst	Pressure, Atm.	Temp., Deg. C.	Space Velocity	4 to 8 Mesh Eff.	8 to 10 Mesh Eff.	12 to 14 Mesh Eff.
C	100	475	5,000	0.950	0.980	0.940
C	100	475	10,000	0.878	0.891	0.880
C	100	475	20,000	0.683	0.717	0.727
C	100	475	40,000	0.514	0.547	0.550
D	100	475	5,000	0.904	0.900	0.897
D	100	475	10,000	0.742	0.730	0.700
D	100	475	20,000	0.567	0.590	0.540
D	100	475	40,000	0.408	0.460	0.380

The individual differences are scarcely greater than the limits of reproducibility of the catalysts. Furthermore, experiments have been carried out on the influence of the shape of the catalyst chamber and no evidence has been found of such influence. Apparently the yield of NH_3 is dependent only upon the amount of catalyst, other conditions being constant, and not upon the size of particle or shape of the container. These facts make possible the direct comparison of the results obtained at the different testing plants, in so far as these effects are concerned.

Influence of Previous History on Catalytic Activity

Chemical composition alone does not, of course, determine catalytic activity. Catalysts of identical composition but different previous history may exhibit widely differing behavior. Whereas the catalysts selected for discussion in this article have in general been subjected to similar treatment, occasional variations, intentional or otherwise, in the routine may have produced certain differences which are especially apparent at low temperatures, where catalytic activity is just beginning. Nevertheless sufficient data are available to enable the drawing of definite conclusions in most cases.

With proper attention to composition of materials and experimental technique, the catalysts selected as typical can be reproduced within reasonable limits. Their characteristics, therefore, may be taken as representing a certain class of catalysts rather than as individual preparations.

Basis of Comparison

In comparing the behavior of catalysts under different conditions of temperature and pressure it is a little difficult to decide upon a satisfactory basis of comparison. From a commercial standpoint either the per cent of NH_3 produced or the yield of NH_3 per hour is most important. On the other hand, in considering the actual activity of the catalyst it must be remembered that the per cent of NH_3 can never exceed that existing at equilibrium and this changes with both pressure and temperature. Comparisons of catalytic activity based upon per cent of NH_3 are therefore apt to be misleading unless conditions of pressure and temperature are identical. Therefore for the purpose of an analysis of catalytic activity under varying conditions of temperature and pressure it seems more logical to select the efficiency (as defined above) as a basis of comparison, although it must be kept in mind that the efficiency may also be a function of the variable conditions and a true comparison of catalytic activity of different catalysts is possible only when conditions are identical. In order to aid in an understanding of the factors which play a part in determining the suitability of a catalyst for commercial ammonia synthesis, the data have been also analyzed upon a basis of the per cent of NH_3 formed and the yield of NH_3.

The efficiency, the per cent of NH_3 and the yield of NH_3 are influenced by four separate variables—pressure, temperature, rate of flow of gases, and concentration of catalyst poisons. The methods used in analyzing the data is in general to plot the efficiency or the per cent of NH_3 as ordinate and one variable factor as abscissa, holding two factors constant. A family of curves is then drawn, each curve corresponding to a different value of one of the constant factors. It would, of course, be possible to construct many additional families of curves from the available data, but it is believed that those selected for illustration serve to indicate sufficiently the general nature of the principles involved.

It is understood, of course, that many other factors besides pressure, temperature, rate of flow and concentration of poison may impose necessary restrictions on the actual conditions of commercial operation. Among these factors are heat losses, ammonia removal, gas

purification, mechanical construction, etc., and no attempt is made to include them in the discussion. It should be emphasized, however, that the determination of the most favorable conditions for commercial operation is a problem of considerable complexity and cannot be intelligently decided upon without a careful consideration of such factors as are discussed in this paper.

Since the "equilibrium values" are referred to frequently, it seems worth while to include for reference a table of these values calculated from the data of Haber by means of the nomograph recently devised by Tour.[1]

TABLE II—EQUILIBRIUM PER CENT OF NH_3, BY VOLUME

Temp., Deg. C.	Pressure, Atmospheres 1	10	31.6	100
400	0.457	4.25	11.45	25.4
420	0.347	3.27	9.10	21.5
450	0.236	2.24	6.45	16.45
475	0.170	1.66	4.93	13.00
500	0.128	1.26	3.77	10.40
550	0.076	0.755	2.32	6.66

Experimental Data

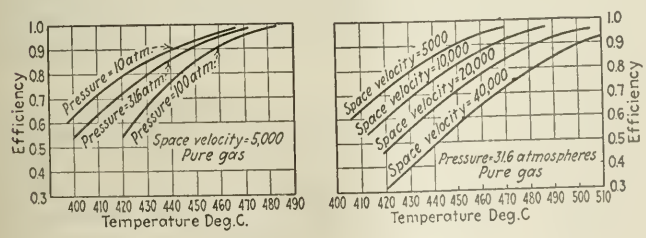
The experimental data which have been selected for analysis in this paper are given in condensed form in Table III. In some cases they represent the average of a considerable number of determinations, in others only a single observation. In any case they represent the best data available at the present time and although further experiment may result in some changes, it is not believed that such changes will necessitate any material alterations in the general conclusions drawn herein.

The Efficiency of Ammonia Formation

The Effect of Temperature at Different Pressures

Every catalyst, in general, requires a certain time at the beginning of a test, and to a lesser extent in changing from one temperature to another, before reaching a steady condition as to ammonia production. This time is naturally greatest at the lower temperatures, when many hours may be required, and much less at high temperatures. The steady condition may be maintained indefinitely if pure gas is being tested. Unless otherwise stated, all results given in this paper will be those obtained after the steady condition has been reached.

Catalytic activity for the type of catalyst in question begins at 400 deg. C. or less and increases with increasing temperature until the condition of equilibrium is approximated (for space velocities around 5,000) at 450 to 475 deg. C. and above, if pure gas is tested. At low



FIGS. 1 AND 2

Fig. 1—Effect of temperature on conversion at different pressures.

Fig. 2—Effect of temperature on conversion at different space velocities.

temperature, and especially at low pressure, the results obtained are apparently so dependent upon the previous history of the particular sample of catalyst that reproducible results are difficult to obtain. Nevertheless, reasonably certain conclusions can be drawn as to rate of change of the efficiency with changing temperature at pressures from 1 to 100 atmospheres. In general, the efficiency always increases with increasing temperature, the rate of change being almost independent of the pressure (Fig. 1). Between efficiencies of 0.4 and 0.85 the increase in efficiency with increasing temperature is nearly linear and the slope is not materially different at different pressures. At efficiencies of about 0.90 the rate of increase with increasing temperature diminishes somewhat, and the efficiency-temperature curves approach the value 1.0 rather slowly. The nature of the curves for low efficiencies is uncertain, owing to the irregularity of the results, but it is probable that a point of inflexion is shown and that the efficiency of zero is also approached slowly at low temperatures.

TABLE III—DATA ON TEST RUNS

Catalyst	Temp., Deg. C.	Pressure, Atmospheres	Space Velocity (× 1,000)	Per Cent NH_3 by Vol.	Efficiency	Composition of Gas

Effect of Temperature at Different Space Velocities

Curves illustrating the effect of temperature upon the efficiency at constant pressure but different space velocities are shown in Fig. 2. From these it appears that between space velocities of 5,000 and 40,000 the general nature of the curves is the same, the effect of an in-

[1] *J. Ind. Eng. Chem.*, vol. 13, p. 298 (1921).

crease in space velocity being largely to displace the curves along the temperature axis.

Effect of Temperature With Poisoned Gas

In Fig. 3, data are plotted illustrating the temperature coefficient of the efficiency at constant pressure and and space velocity, with pure gas and with gas poisoned with carbon monoxide and water vapor. The data are not altogether conclusive, but they indicate that the effect of poison is largely to displace the curves along the temperature axis.

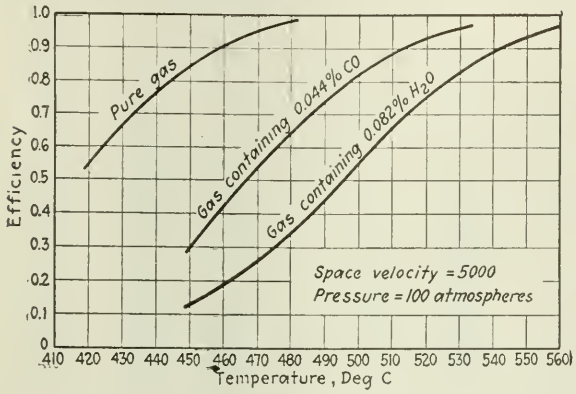

FIG. 3—EFFECT OF TEMPERATURE ON CONVERSION WITH POISONED GAS

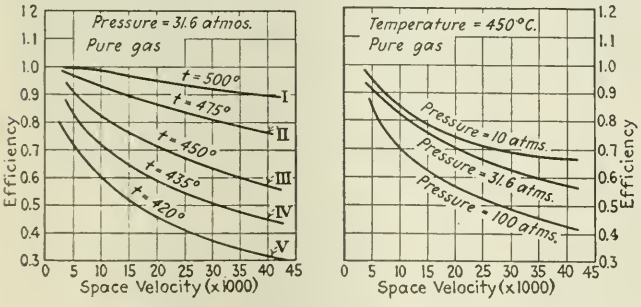
Although the data are not sufficiently concordant or complete to permit a mathematical formulation, it is apparently true that the curves expressing the change of efficiency with temperature are always of the same type, showing a point of inflexion and slowly approaching the efficiency unity at high temperatures and zero at low temperatures. The effect of a change in pressure or space velocity or the introduction of poison is largely that of displacing the efficiency-temperature curves along the temperature axis.

Effect of Rate of Flow on Efficiency at Different Temperatures

The effect of the rate of flow of gas upon the efficiency can be predicted to a certain extent from *a priori* consideration. Thus at zero space velocity the efficiency

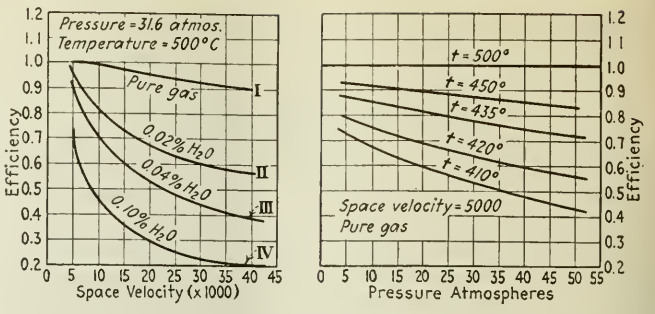


FIGS. 4 AND 5

Fig. 4—Effect of rate of flow of gases on conversion at different temperatures.

Fig. 5—Effect of rate of flow of gases on conversion at different pressures.

must be unity under any conditions and (excluding the possibility of complications arising from lack of turbulent flow at extremely low space velocities) as the space velocity becomes finite, the efficiency will in general remain approximately unity for a range of space velocities which will be greater the higher the temperature, the more active the catalyst and the purer



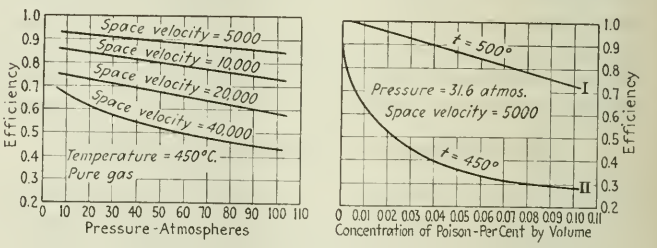
FIGS. 6 AND 7

Fig. 6—Effect of rate of flow of gases on conversion with poisoned gas.

Fig. 7—Effect of pressure on conversion at different temperatures.

the gas. Also, at very high space velocities the efficiency may be expected to approach zero asymptotically. Between these two extremes the nature of the efficiency-space velocity curves cannot be predicted, except that a point of inflexion must occur somewhere.

These considerations are in general borne out by the result of experiment. Thus data obtained at constant pressure (31.6 atm.) and different temperatures are expressed graphically in Fig. 4. It will be observed that at 500 deg. C. the efficiency is practically unity at space velocities up to 10,000, while at 420 deg. the efficiency



FIGS. 8 AND 9

Fig. 8—Effect of pressure on conversion at different rates of flow.

Fig. 9—Effect of poisons on conversion at different temperatures.

is far below unity even at 5,000 space velocity and begins to decrease much less rapidly at a space velocity of 40,000.

Effect of Rate of Flow at Different Pressures

Very little data are available on the effect of space velocity on the efficiency at atmospheric pressure, due to the fact that the increase of frictional resistance of the catalyst mass and the apparatus at high space velocities makes the exact pressure within the catalyst a matter of some doubt, and the rapid variation of the equilibrium with the pressure makes estimates of the efficiency uncertain.

Data obtained at 10, 31.6 and 100 atmospheres, however (Fig. 5), indicate that the effect of changing rate of flow of gases upon the efficiency follows the same general principles at all pressures. At any given temperature, however, the slope of the efficiency-space velocity curves increases somewhat with increasing pressure.

Effect of Rate of Flow With Poisoned Gas

Relatively little data are available upon the effect of rate of flow of gases with gas containing poisons. Characteristic data are illustrated by the curves plotted in Fig. 6. It is apparent that the general nature of the efficiency-space velocity curves is the same for pure and

for poisoned gas, the effect of poison being similar to that of a reduction of temperature (compare Fig. 4, curves I and V, with Fig. 6, curves I and III).

The Effect of Pressure at Different Temperatures

A great deal of catalyst testing has been done at low pressures, especially atmospheric, because of the ease with which such tests can be carried out, and for this reason it is a matter of great practical importance to determine to what extent results obtained at one pressure may be used to predict results at other pressures.

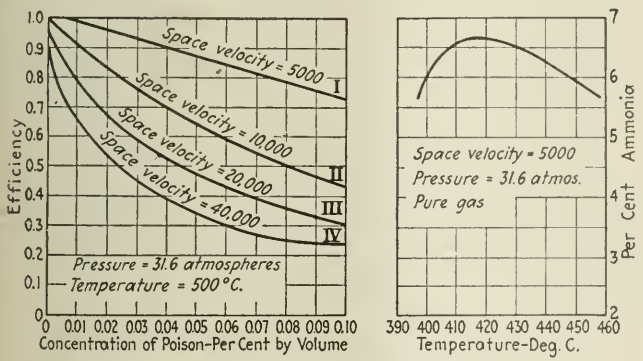
From the data plotted in Fig. 7 it appears that at constant temperature and space velocity the efficiency always decreases slowly with increasing pressure, the effect being greater the lower the temperature selected for test.

Effect of Pressure at Different Rates of Flow

Since, as indicated above, the decrease in efficiency with increasing rates of flow of gases is somewhat greater at high than at low pressures, it follows that the decrease in efficiency produced by increasing pressure must also increase with increasing space velocity. That is $\left(-\frac{dE}{dP}\right) S.V.$ increases with increasing space velocity within the range of space velocities for which data are available—up to 40,000. This is illustrated by the curves in Fig. 8.

Effect of Pressure With Gas Containing Poisons

The data on poisoned gas are somewhat irregular and inconclusive, their interpretation being made more difficult by the progressive permanent deterioration of the catalyst (discussed below) which may occur especially



FIGS. 10 AND 11

Fig. 10—Effect of poisons on conversion at different rates of flow.

Fig. 11—Effect of temperatures on ammonia content at constant space velocity and pressure.

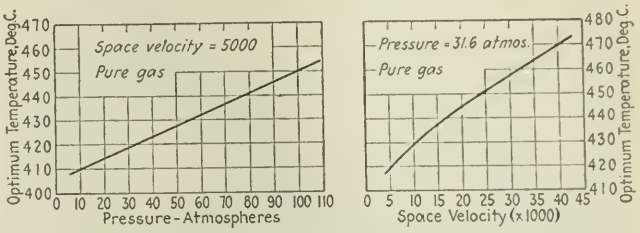
in long-continued tests. However, all of the available data point to the conclusion that the decrease in efficiency produced by increasing pressure is greater for poisoned gas than for pure gas.

In general it appears to be true that if the catalyst is operating under such conditions that the efficiency is close to unity $-\frac{dE}{dP}$ will be relatively small. For conditions under which the efficiency is somewhat lower, whether produced by low temperature, high space velocity or poisons, $-\frac{dE}{dP}$ will be greater. However, if the conditions are such that the efficiency is very low (approaching 0) the value of $-\frac{dE}{dP}$ will again become small.

All of these facts must be borne in mind in comparing results obtained at different pressures and in attempting to predict the behavior of a catalyst at one pressure from data obtained at other pressures. In particular, attention may also be called at this time to the fact that the decrease in efficiency with pressure has been found to be much greater for some catalysts than for those described in this paper. Hence tests which show a catalyst to be very active at 1 atmosphere pressure cannot in general be taken as indicating that the catalyst will be active under conditions suitable for commercial operation.

The Effect of Poisons at Different Temperatures

The only two catalyst poisons studied in any quantitative way are carbon monoxide and water vapor, these being the two impurities most difficult to remove from commercial nitrogen : hydrogen mixtures. Most of the



FIGS. 12 AND 13

Fig. 12—Effect of pressure on optimum temperature.

Fig. 13—Effect of space velocity on optimum temperature.

experimental data have been obtained with only one or two concentrations of poison and even these results are less reproducible than the data obtained when pure gas is used. The conclusions as to the variation of the efficiency with the concentration of poison are therefore more tentative than is the case with the data on pure gas. Nevertheless, certain generalizations seem reasonably certain.

In general, it may be noted that as far as the data are available, no difference can be detected between the effect of carbon monoxide and that of water vapor, if equivalent volume percentages of either gas are considered. This is perhaps to be expected, as at the temperatures in question carbon monoxide is readily converted into water vapor by the catalyst, according to the reaction

$$CO + 3H_2 = H_2O + CH_4$$

In the discussion, therefore, data obtained with either poison will be plotted upon the same curves and treated as though only one poison were being considered.

In general, either poison produces a lowering in the efficiency, this lowering always increasing with increasing concentration of poison. Comparing the results at different temperatures, it will be seen from the curves in Fig. 9 that the lowering in efficiency produced by any given concentration of poison is greatest at low temperatures and decreases with increasing temperature, so that at 500 to 550 deg. C. for low space velocities and low concentrations of poison the efficiency may be unity, as it is on pure gas.

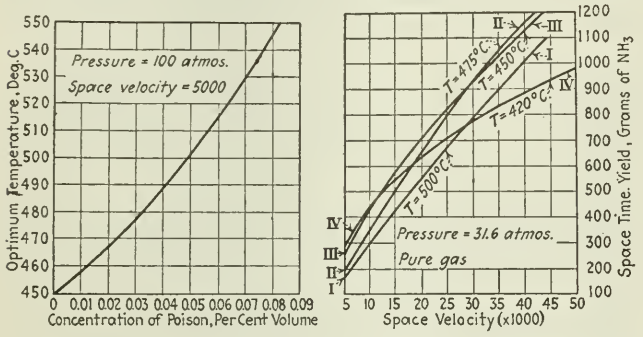
The rate of change in the efficiency with increasing concentration of poisons $\left(-\frac{dE}{dC}\right)$ is itself a function

of the temperature. Thus at high temperatures the efficiency decreases nearly linearly with increasing concentration of poison, while at low temperatures a large initial decrease in efficiency is followed by a much more gradual decrease (compare curves I and II, Fig. 9).

It should be noted that complete recovery of the catalyst occurs when again tested upon pure gas after treatment with poisoned gas, provided the time of treatment with poisoned gas was short. After more extensive tests on poisoned gas and especially at high pressures, permanent injury to the catalyst results. This is discussed further below.

The Effect of Poisons at Different Rates of Flow of Gases

The decrease in efficiency produced by a given concentration of poison in the gas alters greatly with the rate of flow of gases. A comparison of the curves in Fig. 10 with those in Fig. 9 shows that the effect of an increase in the space velocity is very much the same



FIGS. 14 AND 15

Fig. 14—Effect of concentration of poison on the optimum pressure.

Fig. 15—Effect of space velocity on space-time-yield.

as that of a decrease in temperature. At high space velocities the initial drop produced by a low concentration of poison becomes greater, while further increase in the concentration of poison produces less and less effect as the efficiency approaches zero.

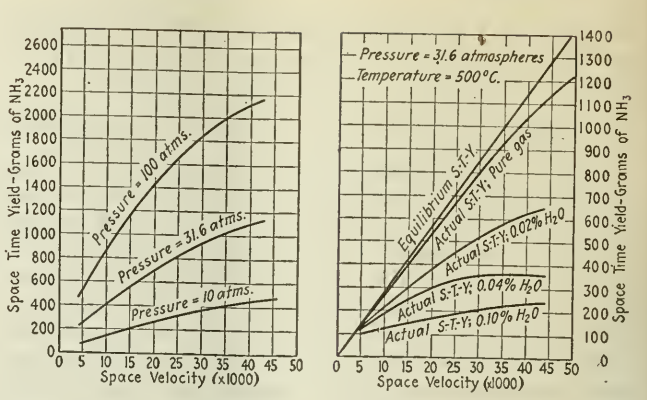
The Effect of Poisons at Different Pressures

The data obtained at different pressures with poisoned gas are scarcely sufficiently uniform to allow definite conclusions to be drawn, but all available data point to the conclusion that the decrease in efficiency produced by a given concentration of poison increases somewhat with increasing pressure. Whether this is true for all temperatures and space velocities cannot be determined from existing data, but it seems probable that the decrease in efficiency with increasing pressure is itself a function of both temperature and space velocity, or more probably, of the efficiency itself.

The Per Cent of Ammonia

The Effect of Temperature at Different Pressures

As pointed out above, the efficiency of NH_3 conversion always increases with increasing temperature, but since the equilibrium percentage of NH_3 decreases with increasing temperature the actual per cent of NH_3 in the gas does not always thus increase. In general, under conditions in which the efficiency is low and increase in temperature produces an increase in the per cent of NH_3, the increase in efficiency more than balances the decrease in the equilibrium value. As the efficiency



FIGS. 16 AND 17

Fig. 16—Effect of rate of flow on space-time-yield with pure gas.

Fig. 17—Effect of rates of flow on space-time-yield with poisoned gas.

approaches unity, however, its increase with increasing temperature is slower than the decrease in the equilibrium value, with the result that a decrease in the per cent of NH_3 results. For any given pressure, space velocity and concentration of poison there will be an optimum temperature, at which the maximum per cent of NH_3 will be obtained from the catalyst under consideration. This optimum temperature is of the greatest importance from an industrial standpoint, as it is an important factor in determining the most economical condition for commercial operation. This optimum (see Fig. 11) is affected by the pressure, the space velocity and the concentration of poison which may be present.

If we compare determinations of the optimum temperature made at different pressures, it appears that the optimum temperature is slowly increased by increasing

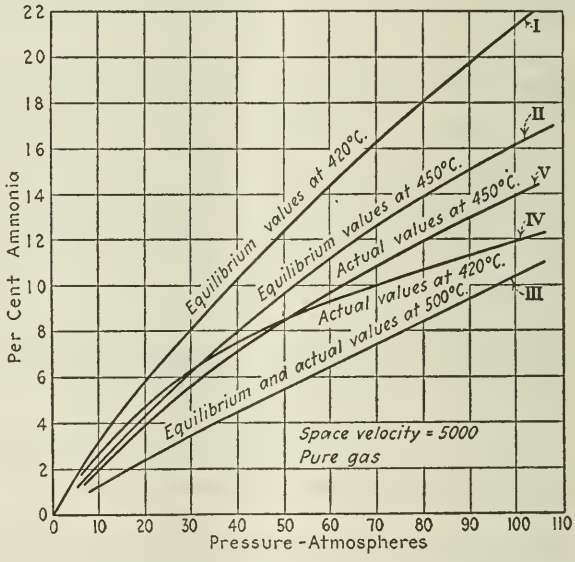


FIG. 18—EFFECT OF PRESSURE ON PER CENT OF AMMONIA AT DIFFERENT TEMPERATURES

pressure. This is illustrated in Fig. 12. Thus in order to obtain the maximum per cent of NH_3 with a given catalyst at a given pressure, the temperature of operation must be somewhat higher at high pressures than at low.

Effect of Temperature at Different Space Velocities

Determinations of the optimum temperature made at different space velocities show that in general at constant pressure the optimum temperature is increased

by increasing the space velocity. This fact is illustrated by the curve in Fig. 13. It follows therefore that the higher space velocity selected for operation the higher the temperature which must be selected in order that the catalyst may give its maximum percentage of NH_3.

Effect of Temperature With Gas Containing Poisons

Since the presence of water vapor or carbon monoxide produces a lowering in efficiency, it is to be expected that the optimum temperature will be higher with gas containing poisons than with pure gas. That this is

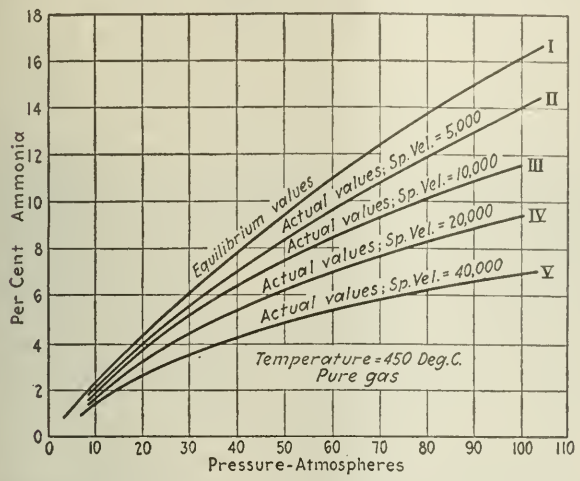

FIG. 19—EFFECT OF PRESSURE ON PER CENT OF AMMONIA AT DIFFERENT SPACE VELOCITIES

the case is shown by the data expressed graphically in Fig. 14, in which it appears that the optimum temperature rises rather rapidly with the concentration of poison in the gas. Thus if the gas contains poisons, it will be desirable to operate at a higher temperature to obtain the maximum output of ammonia than would be the case if pure gas were being used.

The Effect of Rate of Flow of Gas at Different Temperatures

Since an increase in the rate of flow of gas produces in general a decrease in the efficiency (see Fig. 4), at constant temperature and pressure, and since the equilibrium percentage of ammonia is constant under these conditions, it follows that the per cent of ammonia must likewise decrease similarly with increasing rate of flow of gas.

However, if the gas, after removal of the ammonia, is to be recirculated over the catalyst, as will be the case in commercial operation, the fact that the per cent of ammonia does not decrease as rapidly as the space velocity increases becomes of importance. Thus if we consider the space-time-yield (the weight of NH_3 per liter of catalyst per hour) we find that in general this increases with increasing space velocity. Data illustrating the increase in space-time-yield with increasing space velocity, at several temperatures, are expressed graphically in Fig. 15.

Consideration of the curves in Fig. 15 shows that at high space velocities, say 40,000, the yield of NH_3 is greater at 475 deg. C. than at any other of the temperatures investigated, while at 20,000 space velocity 450 deg. C. shows the greater yield, and at 5,000 space velocity the yield is greater at 420 deg. C.

It would appear at first sight that economical commercial operation would require the use of high space velocities, since the weight of ammonia produced per hour by a given mass of catalyst is highest under these conditions. This would undoubtedly be the case if high rates of flow of gas did not entail difficulty and expense. As higher rates of flow are considered, a point will be reached when the increased yield of NH_3 is more than offset by the increased cost of operation. It should be possible by experiment to determine the optimum rate of flow for any given installation.

Effect of Rate of Flow of Gas at Different Pressures

Data showing the increase of the space-time-yield with increasing space velocity at constant temperature and at different pressures are expressed graphically in Fig. 16. The effect of pressure upon the equilibrium values is so great that it masks any other effect, so that the space-time-yields at higher pressures are invariably greater than those at the lower pressures. This is better shown in Fig. 20 and discussed below.

Effect of Rate of Flow of Gas With Gas Containing Poisons

Since, as has been previously shown (see Figs. 9 and 10), the efficiency of NH_3 conversion is lowered at any space velocity by the presence of poisons in the gas and since the equilibrium values are not changed, it follows that the per cent of NH_3 will be correspondingly lowered by the poison, and no further discussion seems necessary. It seems desirable, however, to consider the effect of poison upon the space-time-yield, and data illustrating this effect are expressed graphically in Fig. 17. These data show that the rate of increase of the space-time-yield with increasing space velocity is much greater

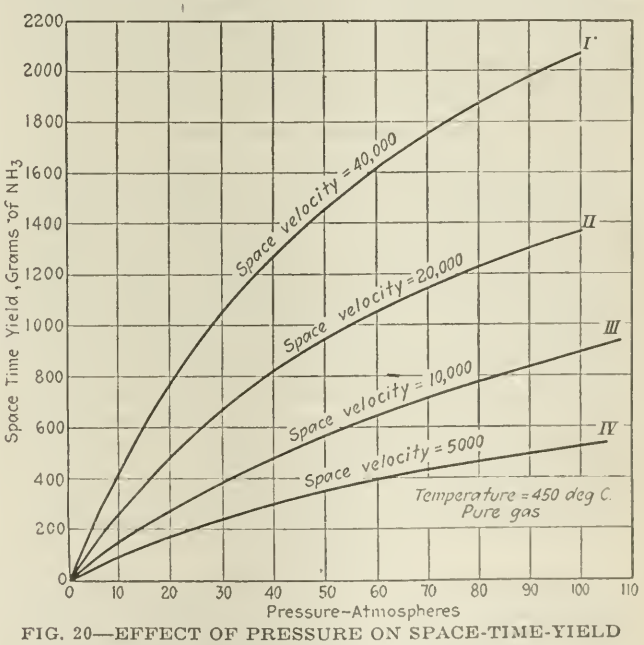

FIG. 20—EFFECT OF PRESSURE ON SPACE-TIME-YIELD AT DIFFERENT SPACE VELOCITIES

with pure than with poisoned gas, so that if high space velocities, say 40,000, are to be employed, thorough purification of the gas becomes more important.

The Effect of Pressure

As indicated above, the effect of pressure upon the equilibrium per cent of NH_3 is so great that an increase in pressure invariably produces an increase in the actual

per cent of NH_3. Figs. 18, 19 and 20 illustrate (*a*) the effect of pressure upon the per cent of NH_3 at different temperatures, (*b*) the effect of pressure upon the per cent of NH_3 at different space velocities, and (*c*) the effect of pressure upon the space-time-yield. Discussion of the curves seems unnecessary. Data on the effect of pressure with poisoned gas are insufficient to permit more detailed conclusions than that the rate of increase of the per cent of ammonia, or of the yield, with increasing pressure is in general much less for poisoned gas than for pure gas.

The Effect of Poisons

Since the presence of poisons does not affect the equilibrium values in any way, the per cent of NH_3 will decrease with increasing concentration of poison in exactly the same way that the efficiency decreases. Since this is illustrated above (Figs. 9 and 10), further discussion seems scarcely necessary.

The Change in the Behavior of the Catalyst With Time

At Different Temperatures

When pure gas is being tested the activity of the catalyst is apparently unaffected by prolonged treatment at temperatures not exceeding 550 deg. C. The tests at 1, 10 and 31.6 atmospheres are usually of only a few days duration at most, and are therefore inconclusive; but the tests at 100 atmospheres are frequently extended over 6 weeks or more, and it is characteristic of the type of catalyst under discussion that its activity is unimpaired at the end of that time, provided the temperature has not exceeded 550 deg. Temperatures above 550 deg. are apt to injure the activity of the catalyst, especially its activity at quite low temperatures. Thus a catalyst which has been injured by high temperature treatment may not show the injury at 500 deg., but may show a distinct loss of activity at 400 deg.

At Different Pressures

As mentioned above, the tests at low pressures carried out in this series of tests have not been continued over sufficient periods of time to be of value in considering the depreciation of catalytic activity with time. Tests carried out on other catalysts, however, which deteriorate more rapidly, have led to the tentative conclusion that deterioration is more rapid at high than at low pressures. This seems the more reasonable because of the fact that at high pressures the "work done by the catalyst" in synthesizing ammonia is much greater than at low pressures. The data, however, are scarcely sufficient to show the point conclusively.

The Effect of Poisoned Gas on the Behavior of the Catalyst

When gas containing carbon monoxide or water vapor is being tested, a slow permanent deterioration in the activity of the catalyst occurs—that is, the catalyst does not regain its original activity when again tested with pure gas. This is illustrated by the data in Table IV.

TABLE IV—RECUPERATIVE POWER OF CATALYST

Pressure, Atm.	Temperature, Deg. C.	Per Cent NH_3	Efficiency	Gas
100	450	14.31	0.878	Pure
100	450	6.04	0.309	0.05 per cent CO
100	450	12.26	0.708	Pure gas after CO treatment for 20 days
100	450	2.13	0.130	0.1 per cent H_2O
100	450	11.00	0.600	Pure gas after CO and H_2O treatment for 31 days.

The permanent deterioration produced by the poison is probably greater the higher the concentration of poison, the longer the time of treatment, the higher the temperature and the higher the pressure. At low pressures (10 to 31.6 atm.) complete recovery of the catalyst may follow several days treatment with poisoned gas, but at 100 atmospheres the original activity is scarcely ever regained.

The available data do not enable us to determine whether or not the progressive deterioration would continue indefinitely or whether it would approach some limiting value with continued testing. Indications favor the latter presumption, since the catalyst will usually give a constant per cent of NH_3 when treated with poisoned gas, even though it may be suffering deterioration—that is, the deterioration is shown by a failure to return to the original activity when tested on pure gas, and not by a gradual decrease in the activity toward poisoned gas.

In conclusion, it may be well to emphasize again that these data have been collected from tests on the three types of apparatus described in the preceding articles of this series. An analysis of the data has been made and tentative generalizations have been drawn, the conclusions being tentative because of the fact that the data are not always complete, and because of the uncertainty that an exact identity of conditions exists in the three plants in all cases.

A New Drop Frame Factory Truck

In handling barrels, bales, bags or heavy rolls, there has been a demand for an especially low loading platform electric truck. The Elwell-Parker Electric Co., of Cleveland, Ohio, has produced, and has had in operation for some time, a truck built up of 95 per cent standard

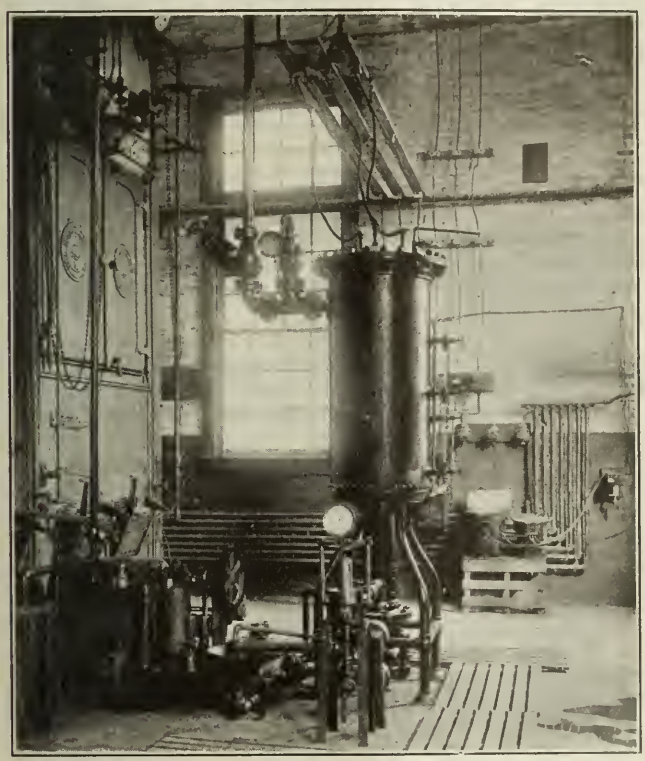
DROP FRAME FACTORY TRUCK WHICH SOLVES MANY PROBLEMS

parts on special frame. This equipment offers the solution to many annoying trucking problems, where hauls are so long that a man with a hand truck is too slow and expensive a means for the movement of materials. This truck carries a storage battery on the upper deck with motor and worm drive axle beneath. All four wheels steer. The "kick-up" on platform houses the rear wheels. Drive wheels are fitted with 21½ x 3½-in. rubber tires and the trailing wheels with 10½ x 5-in. tires. The truck will operate 15 to 20 miles on a single battery charge.

Electric Steam-Generator

AN ELECTRIC steam-generator utilizing the principle of heating produced by resistance to flow of electric current through water has recently been placed on the market by the Electric Furnace Construction Co., Philadelphia, Pa. In this apparatus steam is generated by high-tension alternating current led through the water to be evaporated by means of electrodes, placed in a vertical tank. The quantity of steam produced, the pressure at which it is generated and the consumption of current are governed by the height of the water in this tank, control being obtained through standard valves. Due to the elimination of the firebox and boiler setting, a great reduction in space required per boiler-horsepower is effected.

Any water that is suitable for the ordinary boiler is satisfactory and it is not necessary to install water-softening apparatus, as the salts in the water settle out as a sludge at the bottom of the tank instead of forming a scale, as in the ordinary type of boiler. This is because no part of the boiler is at a higher temperature than that of the steam. Corrosion is also eliminated for the same reason. The only part subjected to much wear is the electrode, which may be easily and cheaply renewed.



ELECTRIC STEAM-GENERATOR INSTALLED AT PLANT OF CANADIAN ELECTRO PRODUCTS CO.

The most important application of the electric steam-generator[1] is in industries located within the range of hydro-electric power plants, where use may be made of surplus power or "spillway" power. It is also possible in some cases to use the excess power at off-peak loads for generating steam and to store this supply of heat or utilize it when available, as a parallel to coal- or oil-fired boilers, thus reducing the fuel consumption. Conditions such as this occur at many paper and pulp mills, and in many other industries. In some districts where fuel is expensive and water power is available the complete substitution of electric steam-generators for boilers heated by other means should prove economical. Under such conditions similar electric steam-generators have already had wide and successful application in Italy, France, Switzerland, Norway and Sweden.

[1]Readers interested in the subject of electric steam-generation may find the following recent journal articles of value: *Engineering*, Feb. 6, 1920 (Revel and Brown-Bouveri type); *Power*, Oct. 12, 1920 (Swiss practice), March 8, 1921 (French practice—Revel type), May 10, 1921 (Swedish installation at Wärgon); *Electrical World*, Aug. 20, 1921 (Brown-Bouveri type), Nov. 19, 1921 (Swedish Forssblad type), Feb. 12, 1921 (Swiss practice—Revel type); *Power Plant Engineering*, Feb. 15, 1921 (Swiss practice—Revel type); *General Electric Review*, June, 1920 (general report); *Can. Synopsis of Recent Chemical & Metallurgical Literature

Crystal Structure of Solid Solutions.—Using the X-ray spectrometer in the manner described in CHEMICAL & METALLURGICAL ENGINEERING, vol. 25, p. 657 (Oct. 5, 1921), and vol. 26, p. 82 (Jan. 11, 1922), Edgar C. Bain reported the results of studies on the "Crystal Structure of Solid Solutions" before the February meeting of the American Institute of Mining and Metallurgical Engineers.

The binary system Cu:Ni is of uninterrupted solid solutions. Since both these metals, when pure, crystallize in the face-centered cubic arrangement and have very similar dimensions (3.60 and 3.54 Angstroms respectively), the space lattices of the intermediate alloys should show the minimum distortion. Investigation of annealed specimens bears this out. All the alloys are face-centered cubes; the size decreases gradually with increasing nickel, an effect exactly similar to the change in a crystal space lattice with temperature.

Gold-copper alloys behave similarly, despite the great difference in size of their crystalline units (face-centered cubes of 4.08 and 3.60 Angstroms respectively). All the alloys are true face-centered cubes; the change in size is mostly confined to the middle half of the range. Thoroughly annealed 75:25 alloys in both of these systems gave some faint lines in the X-ray crystallogram which were identified with a cubic system just twice the size of the dominant one. Evidently this is what should occur in a 3 to 1 alloy if it were homogeneous—i.e., the atoms of the solute equally distributed among the atoms of the solvent.

Metals which crystallize in different crystalline types and yet form uninterrupted solid solutions act differently. The dominant partner or solvent absorbs a certain amount of the other with no measurable distortion of its space lattice. For instance nickel (face-centered cubic; 3.54 Ang.) will absorb 65 per cent of chromium (body-centered cubic; 2.90 Ang.) without distorting its space lattice. Alloys containing from 65 to 95 per cent Cr show space lattices of *both* constituents; chromium appears to be able to absorb only 5 per cent Ni into its normal structure. Copper and manganese act similarly. There is an overlap (where both crystallograms are produced in one alloy) between 60 and 90 per cent manganese. This series has a minimum melting point at 870 deg. C., at 30 per cent manganese.

Bain thinks that this "overlap" denotes the presence of crystals of both types (either pure metal or conjugate solutions) in the metal, despite the fact that microscopic examination shows only one phase. Annealed samples show a very coarse grain, and the dominant partner gives a "dashed" crystallogram characteristic of large crystals. The other metal simultaneously prints a finely penciled set of lines characteristic of a fine-grained sample,[1] and possibly exists in sub-microscopic particles.

Iron-nickel alloys exhibit the effect of allotropy. Alpha iron is body-centered cubic (2.86 Ang.) whereas gamma iron is almost exactly like nickel (face-centered cubic, 3.54 Ang.).

[1]"Mixed Orientation Developed in Crystals of Ductile Metals by Plastic Deformation," by Bain and Jeffries, CHEM. & MET. ENG., vol. 25, p. 775 (Oct. 26, 1921).

Alloys up to 25 per cent nickel, even if annealed, show only the crystallogram of alpha iron. However, if the gamma state in iron is preserved by quenching, the pattern due to nickel is exhibited nearly to pure iron.

Soft Spots After Case-Hardening.—H. W. McQuaid and E. W. Ehn; metallurgists for the Timken Roller Bearing Co., presented an important paper before the February meeting of the American Institute of Mining and Metallurgical Engineers on "Effect of Quality of Steel on Case-Carbonizing." In the manufacture of roller bearings, the parts, made of low-carbon steel, are carburized and heat-treated with the utmost care and under strictest control, so as to produce greatest uniformity in the product. Yet often whole heats would show nearly 100 per cent rejections on account of soft spots discovered when testing the hardened pieces with a file. Chemical analysis failed to show any differences from other heats which acted properly, nor was the carbon in the case materially lower. Special attention to the cementation and hardening did not remove the trouble, nor did recarburization or change in the cement help any. Samples of this "off" steel, when packed in the same box with other steel known to be normal as far as carburization was concerned, would still be soft at final inspection, although the comparison pieces hardened perfectly.

It was found that the behavior on hardening could be predicted by microscopic examination of the carburized pieces, as indicated in Table I. A good case is shown in Fig. 4, while a bad one is shown in Fig. 1.

Zone	Good Steel	Bad Steel
Hypereutectoid case	Large uniform pearlite grains	Small pearlite grains
	Uniform thin Fe_3C network	Massive Fe_3C films
Eutectoid zone	Deeper and thicker than in bad steel	Surrounded by ferrite Shallower and thinner than in good steel
Hypoeutectoid zone	Coarse crystalline	Isolated fine ferrite areas
	Continuous bold ferrite network	
Core	Normal angular pearlite areas	Banded ferrite and with ghost lines

Pieces from each stage of manufacture were carburized, and a defective steel proved a poor carburizer back to the ingot. It was therefore concluded that the trouble originated in the furnace. It has been Messrs. McQuaid and Ehn's practice, therefore, to pour a small ingot at the middle of each cast, forge it down to a bar, and heavily carburize this bar. If the cementite near the surface appeared in divorced masses, the heat would not be accepted. Co-operation on the part of the steelmakers was obtained after the Timken company had demonstrated that this test was able to segregate a group of samples submitted by the steel company with secret marks and from heats some known to be bad, others known to be correctly made with great care.

While the exact mechanism of the pearlite divorce is unknown, it is thought by the authors to be a characteristic of oxide included in the metal. For instance, fairly good steel may have a ghost line here and there, and this ghost line will persist throughout carburization and be the locus of divorced cementite. No phosphorus bandings are developed in such steel by cupric reagents—indeed, 24 hours at 925 deg. C. in the carburizing pot should give ample time for equalization of soluble phosphides. If the surface of a small ladle of molten electric steel—a steel which carburized perfectly—is blown slightly with oxygen gas, that sample when carburized shows a complete breakdown of pearlite into massive ferrite and cementite. Figs. 1 to 4 show samples taken from an electric furnace at various times during the heat—it is evident that the microstructure of the case is not correct until after the charge has been deoxidized with ferrosilicon. Brearley thinks that soft spots on case-hardened work are due to low manganese in the stock, an idea which the authors harmonize by saying that low manganese means excessive loss of the ferro or spiegel added, and consequently an overoxidized heat of metal.

The Importance of Low Handling Costs.—In a paper on this subject in *Chemical Age* of London for Feb. 25, 1922, Herbert Blyth states that if the chemical industry is going to perform all the great things that are expected of it for the benefit of mankind, it will have to be invigorated by the sweeping away of inefficiencies and the employment of modern methods. He states that in nearly all chemical works the want of efficient unloading and conveying equipment is one of the chief causes of the high cost of production, it being an established fact that the cost of the product is almost directly proportional to the cost of simply moving the material into the works, through the plant, and out of the works again. Another factor is the speed of handling the material. If production is kept at full capacity by proper feeding of materials, cost will naturally be much less than with restricted delivery of material.

In the matter of unloading bulk materials from car or barge notice is taken of the convenience and economy obtained through the utilization of pneumatic methods. The advantage of this method lies in the continuous nature of the duty performed and the elimination of hand labor in trimming; but the method can be used only for a practically dry and fairly fine material. For coarse or moist materials the crane and bucket unloader is recommended.

For handling from the unloading point the belt conveyor is recommended when the route is straight, unobstructed, and not too long. For heavy material, or material discharged into a pit by bottom dump cars, which involves a lift as well as a horizontal movement, the monorail carrier is recommended. The final choice of the handling method used must rest on a study by the chemical engineer, the mechanical engineer and the financial man of the material to be handled, its tonnage, and the route over which the handling is to be done, together with the cost of the various methods available.

In conclusion, it is stated that the chemical industry has not hitherto properly investigated its handling problems or taken serious notice of the improved equipment available. The objects of every industry are to cut production costs, increase output and improve plant conditions, and a great deal can be done toward the achievement of these objects by the adoption of suitable methods of handling the raw materials and products.

Book Reviews

STEEL MILL BUILDINGS. Fourth Edition. By *Milo S. Ketchum.* New York: McGraw-Hill Book Co., Inc. Price $6.

In this book is found an old friend in a new flexible cloth binding well suited to constant and hard usage. The author has re-written much of the book and added a considerable amount of subject matter and many instructive drawings and diagrams, including very valuable data on a number of proved building materials developed since the earlier editions of this book, and a large variety of the newer type of building construction. In the preparation of drawings and diagrams, the work has been carried out in an exceptionally neat, orderly and well-arranged manner, using plain lettering of nearly uniform character throughout the book and offering a very excellent example to the student during his habit-forming years.

It is doubtful if some of the tables, those also found in the handbooks published by various steel companies, will prove of much value to or be often used by the experienced engineer, but since the work is also offered as a text book for students, they may well serve a useful purpose.

Special credit is due the author for putting in concise form the analysis of stresses in statically indeterminate structures of a wide variety, a subject hitherto involving so much sifting of chaff from the wheat that the busy engineer has shown a marked tendency to avoid many useful forms of structures entailing such calculations. L. W. EMERSON.

CONDENSED DESCRIPTION OF THE MANUFACTURE OF BEET SUGAR. By *Franz Murke, Ph.D., A.M.* 5 x 8½, v + 175 pages. New York: John Wiley and Sons, Inc., 1921. Price $2.50 net.

Dr. Murke's book directs more attention to the principal operations of beet-sugar factories than to the equipment used. This is an excellent feature. Another good feature is the running commentary on the mistakes and difficulties commonly encountered, including methods of avoiding or overcoming them. In this latter the author gives us a liberal helping from his own store of wisdom accumulated through years of experience and comparative study of the operations of several factories. The style is very concise and usually clear, but the brevity has been carried to the extremity of omitting illustrations, diagrams and even tables of analytical data showing the successive changes in the products as they advance through the process. The book therefore is addressed (in the preface) especially to readers who already have a respectable knowledge of the process. But since there is very little about the relations of the various operations one to another or to the process as a whole, one of its greatest potential values has not been developed. Treatment of the operations in flow-sheet sequence was perhaps thought sufficient.

Although the book was mainly written several years ago, it has been brought generally up to date. Some exceptions to this are the omission of modern devices applied to the cleaning and handling of beets, the recommendation of daneks for thin juice filtration (p. 50) and the treatment of reactions from the standpoint of the old chemistry rather than of modern colloidal and physical chemistry. The discussions of such obsolete practices as the bluing of sugar (p. 91) and the osmose process take up space that could have been given to more valuable features.

There is little to stimulate new thinking, or to indicate lines of probable future development. The style is usually one-sided and conservative. Some poorly constructed sentences and numerous awkward or half-Anglicized expressions such as "after-purification," "healthy juices," "maishing," "wagons . . . carried on rails" (for "dump-cars"), etc., mar the usual perspicuity. The frequent allusions to European practice would be more valuable if they were complete enough to give the reader a clear idea of what is most general there and how it differs from American practice.

The absence of an index will discourage the use of the book as a handbook. There is no bibliography or other guide to the literature of the subject of beet-sugar manufacture or of the individual operations used, and Claassen is the only other authority cited. The six tables and two or three formulas making up the last chapter are useful, but it would seem desirable to have included also some equally useful but less readily available data.

The book is very readable and should prove valuable to chief chemists, foremen and others who are in the stage of secondary training in the subject and interested especially in the operation rather than in the engineering side of it. In fact, it is surprising on the whole how much useful information of this type is included in the 155 pages of text proper. In some respects the treatment is often better than in most other books on the same subject. For example: (1) Without saying so, the author shows that the diffusion process is ordinarily one of continuous extraction with intermittent charging of fresh beets and discharging of exhausted pulp and that it is not intermittent counter-current extraction as some books would lead one to believe. (2) The saving in steam and condenser-water by the application of vapor-heating is shown. (3) The starting, operation and closing down of a limekiln is described so simply and yet so definitely that anyone who has read it would probably not make such blunders as we sometimes hear about in connection with this station.

Aside from the texts prepared by some of the sugar manufacturers for the instruction of their employees, which, however, are not readily available, it is the best book on American practice. M. J. PROFFITT.

JOURNAL OF THE INSTITUTE OF METALS, vol. 26. Edited by *G. Shaw Scott.* 8vo. 760 pages. London: The Institute, 36 Victoria St., S.W.1. Price 31s. 6d.

Again the British Institute of Metals is to be congratulated upon a very attractive and useful book, published and in the hands of their members within 5 months after the autumn meeting. It contains not only the technical papers presented at that time, and 120 pages of discussion thereto, but the May lecture on "Casting of Metals," by Prof. Thomas Turner, 200 pages of abstracts from current metallurgical periodicals, and a considerable mass of society news. Indeed, the bulk of the volume is growing apace. However, in the opinion of the reviewer, the present volume could be compressed by 100 pages, partly by elimination of matter of purely temporary interest and which, on this side at least, would be placed in the hands of the membership through bulletins or circulars, and the remainder through a typographical rearrangement of the index.

A continuation of the notable papers on light alloys is noted in an extended discussion of constitution and age-hardening of Al:Mg:Si alloys by D. Hanson and Marie Gayler. Most of the other papers deal with the properties of worked metal (pure copper and zinc) cold drawing of bronze, and extrusion. G. D. Bengough also adds a summary of the findings of the Corrosion Committee, having special reference to methods which may be adopted to minimize corrosion of brass condenser tubes. Laboratory men will be interested in the papers on electro-etching and scleroscope tests on thin specimens. New copper alloys of promise with up to 8 per cent nickel and 10 per cent aluminum are discussed by A. A. Read and R. H. Greaves. Foundry practice is touched upon in papers on the effect of lead in Admiralty mixture, and the density of brasses. In this vein, R. Genders presented a very interesting note on the casting of brass ingots, wherein he notes that rejections due to pipe and inclusions in hollow drawn 70:30 brass articles were reduced from 25 per cent to nearly zero by using best steel-teeming practice. Long narrow ingots, 1½ in. square, 6 or 7 ft. long, were replaced by others 30 in. long, tapering from 3½ to 3 in. square. These were set big end up, the top surmounted by a hot fireclay top, a "dozzle," and the teeming slowed down so that when cast the ingot was solidified and much colder at the bottom than at the top. E. E. THUM.

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Week's Testimony in Dye Investigation Brings No Substantiation or New Developments

The sensational developments which rumor had promised would be disclosed when the testimony of dye importers was heard before the Senate sub-committee have apparently fallen as flat as Senator King's original charges. The testimony of Herman A. Metz, importer and manufacturer, disclosed nothing more startling than a personal animosity between himself and Francis P. Garvan, former Alien Property Custodian.

For the rest, the King charges have been somewhat lost in the shuffle of witnesses entering an eleventh hour agitation for tariff protection. Charges and counter-charges which have characterized the entire investigation promise to pass into the record without substantiation. Senator Shortridge's comment on some of Mr. Metz's statements to the effect that his statement was "argument and inference" drew from the latter a reply which seems to summarize the situation. "That's all we've had from either side," said Mr. Metz.

Metz Continues Reading of Testimony

The testimony of Mr. Metz occupied four days of the hearing. He began the reading of his lengthy statement on March 23 and concluded March 29. In his testimony, Mr. Metz went into the details of his troubles with the Alien Property Custodian and attempted to defend his stand in opposition to the dye embargo. He seemed very bitter in his resentment of the action brought against him during the war by F. P. Garvan, declaring that the latter "sought to ruin me in the interest of those in whom he was interested."

"I was evidently German when it suited his purpose," he stated, "but was 100 per cent American when I took stock in his Chemical Foundation or was granted licenses by the Foundation under patents they claimed to own."

He had refused to surrender the stock of H. A. Metz & Co., and the H. A. Metz Laboratories, Inc., upon demand of the Alien Property Custodian, Mr. Metz said, and had obtained a temporary injunction in New York enjoining the Custodian from taking any action on the stock of those companies. Metz had instituted proceedings to recover the stock of the Farbwerke-Hoechst Company.

He had consulted Charles E. Hughes, now Secretary of State, he said. "Pending a hearing on the temporary injunction, Garvan tried to arrange by stipulation just under what conditions I was to deposit the stock, because I told Judge Hughes I positively refused under any condition to allow Garvan to put his directors into my salvarsan plant and if he did, I would close the plant and take every man out.

"Various stipulations were suggested but I refused them, all of them, even when Judge Hughes told me I was running risk of being indicted, as under the Alien Property Custodian law his determination was sufficient, and I had redress under section 9. I realized there was no redress after once my property had been taken. I had been damaged enormously by the reports of Garvan's seizure and the stories circulated by my competitors about being German, all of which was enough to condemn anyone in those days."

Criticizes Institute and Foundation

The witness brought Judge J. Harry Covington, a former member of Congress from Maryland, and now counsel for the American Dyes Institute, into his testimony, declaring that he had been active before Congress in support of embargo legislation for American dye manufacturers.

Mr. Metz went into much detail concerning his relations to the American Dyes Institute and the Chemical Foundation. He charged that the principal activities of the first had been in obtaining legislation and said that the second "posed as a quasi-public organization, whereas there is nothing public about it."

Mr. Metz told in detail of his manufacture of salvarsan, declaring that the service he had rendered in this connection would have been rendered if the Chemical Foundation, which holds a patent for its manufacture, had never been heard of, as he manufactures under a patent from the Federal Trade Commission.

In answer to questions from Chairman Shortridge, the witness declared himself in favor of protecting the domestic manufacture of salvarsan by an ad valorem rate of 50 or 60 per cent plus a specific duty.

"A specific rate of 7 to 10 cents a pound would protect us on dyes, but not on salvarsan," he said.

Touching on the value of the patents taken over by the Chemical Foundation, Mr. Metz declared that the salvarsan patent was "worth a million dollars to anybody"; that the indigo patent was very valuable and that the patents of the Bayer Co., seized and sold during the war, were worth several millions. Mr. Garvan, as Alien Property Custodian, knew that they were worth "a great deal more" than the $250,000 paid by the Chemical Foundation, he added.

The witness attacked the policy of the Dermatological Research Institute of Philadelphia. Although not run for profit, he said, the Institute sells its product in the open market in competition with those manufacturing for profit. The difference is, according to the witness, that he had to pay taxes to the government on his profits while the Institute did not. He declared that the Institute had made $500,000 in profits from its manufacture and had "presented" this to itself, not for profit, but for further research work.

No Dye Monopoly, Says Metz

"There is today no monopoly in the American dye and organic chemical industry, but the strongest kind of competition; everybody is trying to turn stocks into cash," Mr. Metz declared. "Banks are calling loans on stocks of dye companies," he continued, "prices are falling and you know when that is going on there is no monopoly."

He estimated that about twenty of more than eighty plants making dyes and chemicals in this country have been forced to close because of decreased consumption and competition. He declared that he had done everything possible to help the American industry, as he wished to see it prosper.

Tariff Would Protect Manufacturers

In answer to questions from the chairman, Mr. Metz said that a tariff can be written which would protect adequately 75 per cent of the dye products made here. The protection should be 50 per cent ad valorem and from 7 to 10 cents a pound specific duty on dyes and the same duties on intermediates. "With that protection, I'll guarantee that my plants will run and make all the products they make today," he added.

Mr. Metz said he had no criticism to make of the men in charge of the licensing system and that it had been administered fairly and well, but he objected to the system as inconvenient and costly to consumers of dyes. He said he was speaking solely in the interests of the consumers.

Textile Man Favors Embargo

Franklin W. Hobbs of Boston, president of the Arlington Mills, Lawrence, Mass., was the first witness following Mr.

Metz. Mr. Hobbs explained that his mills manufacture worsteds used in men's and women's wear and dye 350,000 yards a week. He announced that he would discuss the question of what is needed for adequate protection of the American dye and organic chemical industry as an American citizen and as a large consumer of dyes.

The substance of his testimony was an expression of confidence in the ability of American dye manufacturers to meet the needs of the textile trades if given proper protection. "We have no complaint to make whatever of American dyes. We use a few foreign dyes, for fancy shades, but I believe these shades will soon be made in this country," he said.

Mr. Hobbs expressed himself in favor of the licensing system, saying: "If we want to be absolutely sure about protection, we're going to get results with the licensing system. You may get it with a tariff, but we are sure of getting it with the licensing system."

H. J. Conn of the Agricultural Experimental Station at Geneva, N. Y., said the American scientific men are interested in the maintenance of the American dye and chemical industry, regarding it as necessary to proper research work. He said about ten American manufacturers have standardized their colors for biological research work. This witness had no opinion to offer as to the best means of protecting the American industry.

Schamberg Defends Dermatological Institute

Dr. Jay Frank Schamberg, director of the Dermatological Research Institute, Philadelphia, commented vigorously on testimony relative to his institution, given by Mr. Metz. Dr. Schamberg said he was at a loss to understand just what Mr. Metz meant by his statement. He said that if Mr. Metz meant that Dr. Schamberg and his associates turned over to an institute incorporated for philanthropic and scientific purposes money which they could legally have retained for themselves, Mr. Metz was correct, but that if he meant that one penny was retained for the personal profit of Dr. Schamberg or his associates, the statement was "a miserable and damnable calumny."

The witness explained that the Dermatological Research Laboratories were established in Philadelphia in 1912, through the generosity of P. A. B. Widener of Philadelphia, who financed their scientific work for four years. After his death further support from this source stopped. These laboratories, the witness explained, were engaged during this period in research work to develop new chemical compounds to combat germs causing infectious diseases.

Continuing, he went into the relations of the Laboratories with Mr. Metz during the war when there arose an urgent need for salvarsan. The primary purpose of his organization in manufacturing salvarsan was to meet this shortage, lower the price to the poor and supply physicians and hospitals. He believed, he said, that these purposes have been fulfilled, as the American product is selling today at about one-fifth the price the Germans received here for their product before the war, and the American product today is the superior, he declared.

"If the German product were allowed to come in, I believe the Germans would be able to close most of our laboratories by price competition," said Dr. Schamberg.

The witness explained that the production of salvarsan is only one of the activities of the Institute, which, he said, is constantly carrying on research work to discover drugs to cure infectious disease and has done so. All profits must be, he said, devoted to the research work.

Helium Research to Continue Despite Opposition

During consideration of the army appropriation bill by the House, Representative Green of Iowa sought to terminate experiments on helium. He took the position that it is not necessary to recover helium, as dirigibles are going out of use. Representative Lanham of Texas defended appropriations for conservation of helium. An amendment by Mr. Green to discontinue the investigation by striking from the bill authorization to acquire land to explore, procure or reserve helium gas as carried by the bill on committee recommendation was rejected, however.

Utilization of Water Power at Muscle Shoals by Haber Process Is Proposed

The Secretary of War has received a proposal for the purchase and operation of some of the Muscle Shoals property from Dr. Charles L. Parsons, representing a group which will organize a company called the Southern Nitrate Corporation. The company will be organized, if the proposal is accepted, and will in turn organize a corporation, the securities of which will be offered to the public.

Details of the Proposal

The company proposes to purchase the first 100,000 kw. of secondary horsepower developed at the Muscle Shoals Dam at a price of 0.75 of a mill.

It offers to purchase Plant No. 1 for $600,000, the purchase price to include everything except the designs acquired from the General Chemical Co. over which the government has jurisdiction. As a condition of the purchase the company will demand the option to lease the carbide plant, part of Plant No. 2, for $50,000 per annum and the option to purchase the Waco quarry property for $200,000 or to lease it for $20,000 per annum.

The company will agree to operate Plant No. 1 as an air nitrogen fixation plant, using as much of the power as is necessary to produce hydrogen for the ammonia process by electrolysis. It further agrees to produce calcium carbide or phosphoric acid and potash by electrothermal methods in the carbide plant. It will maintain a research laboratory and keep all leased property in good condition for the use of the government in case of emergency. It will also agree, in case the government leases the rest of the cyanamide plant, to supply the lessee with calcium carbide at 6 per cent profit as well as nitrogen and power at cost.

Advantages of the Haber Process

In presenting the proposal Dr. Parsons pointed out that the decreasing importance of the cyanamide process for nitrogen fixation was due to the rapidly increasing success of the Haber process. Already the General Chemical Co. has a very successful plant in operation at Syracuse, N. Y. A large plant for producing 100 tons of fixed nitrogen per day is under construction at Billingham, England. Prof. Claude has constructed a remarkable plant in France which operates on the same principle but under much higher pressures. In Italy and Japan similar plants are under construction. Finally, a large cyanamide plant in Odda, Norway, almost half as large as Muscle Shoals, was sold for the equivalent of $10,000, which is scrap value. This Norwegian company plans to install a Haber process plant. All of these data were presented with a view to substantiating the claim that the Haber process is more desirable than the cyanamide process—a better commercial possibility. This particular point has been the subject of a very important controversy which originated in the discussion of the Henry Ford offer.

The company which will be organized by Dr. Parsons is in no way connected with any of the other parties who have made proposals on the Muscle Shoals project. It is not primarily interested in the "philanthropic production of fertilizer," but claims to be a business organization organized to develop a profitable industry.

Such a plant, it is claimed, will be able to produce enough nitrogenous fertilizer at a relatively low cost to stabilize the price of the commodity in this country and lower the cost to the consumer. In addition to fertilizer it is planned to produce calcium carbide and acetylene for autogenous welding. Finally, if development work indicates that the process will be successful, phosphoric acid and potash will be produced by electrothermic methods in some of the carbide furnaces.

Date of N. J. Society Meeting Changed

The April meeting of the New Jersey Chemical Society will be held on the 17th, instead of on the second Monday as usual. The speaker will be Prof. W. D. Harkins of the University of Chicago, who will talk on "Isotopes and the Building of Atoms."

Revival of Patent Convention With Germany Delayed—Working Clause Proposed

The President is understood to be satisfied that it would be unwise to revive the patent convention of 1909 with Germany. The Senate recently authorized the President to revive this patent convention, but it is believed that the Senate action was taken without a thorough understanding on the part of most members that it would exempt German patents taken out in this country from any working clause that might be enacted. The convention also exempts American patents registered in Germany from any working clause which might be adopted in that country. There are certain American industries which are very anxious to have that safeguard, but the arrangement would be particularly harmful to the chemical industry.

The whole matter of a patent working clause is to be threshed out at once. Senator Stanley of Kentucky has introduced a bill which has been approved by the War Department. Public hearings on the bill have been called for April 5. The salient feature of the Stanley bill provides that "any patent or patents issued to any person or persons under the provisions of this act shall contain a proviso to the effect that if such patent so granted is not worked or put in operation so as to result in actual production in the United States of the article embodied in such patent in reasonable quantities within a reasonable time from the date of its issue, which in no case shall be less than 2 years nor more than 5 years, the United States reserves the right to license any person or persons for purposes of manufacture in the United States, and to use and sell the subject matter thereof subject to the conditions hereinafter provided."

In all probability the definition of a reasonable time will be altered so as to leave it to the discretion of the administrative officer.

Societies Co-operate in Work on Corrosion Under Committee of National Research Council

The National Research Council recently appointed a committee connected with its Division of Research Extension with the following membership:

W. M. Corse, chairman, Monel Metal Products Corporation, Bayonne, N. J.; Wilder D. Bancroft, Cornell University, Ithaca, N. Y.; John Johnston, Yale University, New Haven, Conn.; G. K. Burgess, Bureau of Standards, Washington, D. C.; D. M. Buck, American Tin Sheet & Tin Plate Co., Pittsburgh, Pa.; William H. Bassett, American Brass Co., Waterbury, Conn.; E. M. Chamot, Cornell University, Ithaca, N. Y., and Colin G. Fink, 101 Park Ave., New York City, secretary.

The purpose of this committee is to serve as a general clearing house and to devote its attention essentially to fundamental scientific study of corrosion. This committee desires to get in touch with all the work that is being done on corrosion whether through societies, associations, institutes, universities or private or industrial laboratories.

Various Societies Have Corrosion Committees

The American Society for Testing Materials has had a committee on corrosion of iron and steel for a number of years, known as Committee A-5. J. H. Gibboney, chemist of the Norfolk & Western R.R., Roanoke, Va., was designated as acting chairman of the committee, following the death of Dr. S. S. Vorhees of the Bureau of Standards, and the secretary is J. A. Aupperle, chief chemist of the American Rolling Mill Co., Middletown, Ohio. The committee is representative of both non-producers and producers of iron and steel, with four sub-committees, one an advisory committee, another a committee on preserving metallic coatings of metals, another a committee on inspection and the last a committee on total immersion tests. It has been decided to establish a further committee (Committee B-3) on corrosion of non-ferrous metals and alloys, representing non-producers and producers.

The American Committee on Electrolysis was organized in 1913 through the activity of some members of the American Institute of Electrical Engineers, representing, in addition to the Institute and the Bureau of Standards, the following organizations: American Electric Railway Association, American Gas Association, American Railway Engineering Association, American Telephone & Telegraph Co., American Water Works Association, National Electric Light Association, National Gas Association of America. This committee is made up of twenty-seven engineers, three from each of the organizations named. This general committee appointed a special research sub-committee of which H. S. Warren, 195 Broadway, New York City, is chairman, and H. C. Sutton, 1401 Arch St., Philadelphia, Pa., is secretary. The Bureau of Standards undertook the investigation of certain phases of the electrolysis problem in 1910 and has since then made important contributions to the subject. At the beginning of the co-operative work between the bureau and the research sub-committee a policy was agreed upon to the effect that the investigations are solely concerned with the accumulation of facts leading to the establishment of principles upon which conclusions and recommendations may ultimately be based. Burton McCollum, of the bureau, has recently proposed an extended series of tests of samples of many kinds of pipe buried in the soils of known special character in selected localities in many parts of our country.

The Engineering Foundation is giving preliminary consideration to a study of that form of corrosion of iron which has been called "graphitic corrosion."

The American Electrochemical Society at its recent meeting named Dr. Colin G. Fink as head of the committee on corrosion investigations.

The Bureau of Mines at its Pittsburgh station is investigating the corrosion of mine waters on metals.

The American Society of Civil Engineers has recently appointed a research committee of which Prof. A. M. Talbot at the University of Illinois, Urbana, Ill., is chairman, and F. E. Schmitt, Associate Editor, *Engineering News-Record*, 10th Ave. at 36th St., New York City, is secretary. The matter of corrosion has not yet been considered by the committee, but undoubtedly will be.

Problems in Corrosion Pointed Out by Colin G. Fink

In a statement designed to co-ordinate the corrosion problems of immediate importance, Colin G. Fink, secretary of the National Research Council committee, calls attention to the widespread importance of work on this subject.

"In spite of the general relaxation in chemical and metallurgical research throughout the country," says Dr. Fink, "a number of the corrosion problems are so very important and their solutions involve such large savings in capital and labor that a number of concerns and government laboratories felt the urgent need of furthering corrosion research during the past year.

"The corrosion problems have been attacked from two more or less different angles. In the one case every effort is being made to arrest the corrosion of the materials now in use; in the second case, new materials are substituted and tried out. There are today a series of distinct corrosion problems, in each instance centered about some specific material or article of manufacture. There is, for example, the problem of the corrosion of food containers and the problem of the corrosion of buried conduits and cables. Besides these specific problems, there are the general investigations on the causes of corrosion under varying conditions and of various materials.

"We cite below a few of the corrosion problems covering specific materials or products; and secondly, a few of the general topics, closely allied to the corrosion problem, which require further study and research:

"Condenser tubes, underground cables, buried iron pipes, posts, etc., fence wire, flues, stacks, stovepipes, steel ships and ship fittings, roofing materials, mine pumps and other mine equipment, atmospheric corrosion of brass, atmospheric corrosion of bronzes, alloys resistant to high temperatures, corrosion of zinc cathodes, contact metals or alloys, catalyzer metals or alloys, cutlery steels, acid tank linings, corrosion of nickel-plated ware, boiler tubes and fireboxes, automobile radiators, insoluble anodes and the

corrosion of iron as effected by the presence of small amounts of other elements.

"General problems include the velocity of corrosion as effected by (*a*) temperature fluctuations, (*b*) alternate dry and moist surface, (*c*) presence of foreign materials, (*d*) presence of oxide or carbonate of one or the other constituent of the alloy, (*e*) crystal structure and intercrystalline cement; the properties of the surface film, (*a*) coefficient of expansion as compared with that of the underlying metal, (*b*) its chemical composition, (*c*) porosity, (*d*) flexibility or ductility, (*e*) coefficient of adhesion, (*f*) speed of renewal of 'healing,' (*g*) relative hardness, (*h*) how affected during mechanical working and finally the general problem of corrosion and bacteria.

Suggests Lines of Endeavor

"A more complete micrographic investigation of the changes taking place in the film and the metal underneath, during the process of corrosion, is very desirable. Furthermore, we shall be able to progress more rapidly the sooner we agree upon standard tests used to determine the relative corrodibility of two samples. At present it is almost impossible to compare the results of one author with those of another, even when both have used the same materials in their tests.

"Within the last year decided progress has been made in cutlery steels, in metals and alloys for mine equipment, in cable sheath, in insoluble anodes and in alloys resistant to high temperatures and the corrosive action of molten metals such as zinc, tin, etc. But the corrosion problem, as a whole, in spite of its long past history, is still in its 'infancy' and it is only through co-operative effort and a free discussion of results (those suitable for advertising purposes as well as those usually suppressed) that consistent forward strides are possible."

Trade Associations Invited to Co-operate

Some associations, like the National Canners' Association, and certain corporations, like the New Jersey Zinc Co. and National Tube Co., have been making studies in corrosion. The committee of the National Research Council will be very glad to be informed of any work on corrosion that is going on or that is in contemplation. Communications should be sent to Paul Moore, secretary, Division of Research Extension, National Research Council, 1701 Massachusetts Ave., Washington, D. C.

Ratification of Gas Treaty Brings Forth Views of Senators on Its Effectiveness

While no vote was cast against the ratification of the submarine and noxious gas treaty, the futility of such an agreement was pointed out with great clearness by Senator Wadsworth of New York. Senator Lodge, in his effort to justify the treaty, said among other things:

"Undoubtedly the number of deaths in this war arising from poisoned wells was very small. Is that a reason for restoring to general use the poisoning of wells which has been driven out of use simply by the effect of public opinion?

"This clause in this treaty is not expected to prevent the use of poison gases at present. It is expected to do something toward crystallizing the public opinion of the world against it, and trying to make that public opinion more effective. I am aware that the losses of life in this war from poison gases were less than those from high explosives and other weapons, but it hardly seems to me an argument to say that because you kill more men with shells, it is well to add another method of killing them.

"It was obvious to the conference that it is impossible to make regulations for the production or the use of these poison gases because they are made in the production of dyes and in all sorts of chemical materials.

"If the world is cursed with another such war, I dare say poison gases will be used again, but there is always the hope that the opinion of the world may be so crystallized that it will prevent it, as public opinion alone practically has prevented the poisoning of wells and the giving of no quarter to prisoners."

Senator Wadsworth declared that "no nation in its senses will dare refrain from developing gases in research." In the debate attention was called to the fact that Great Britain intends to experiment actively with gases, not with the idea of precipitating their use, but with the idea of being in readiness in case another country should use them. Senator Wadsworth pointed out that we are doing the same thing. In that connection he said:

"We cannot stop the development of gases. It will go on inevitably, to the end of time, in my humble judgment. I will not be surprised if chemical warfare, developed to its highest point of perfection, will make war infinitely more merciful than it is today. It is quite within the realm of possibility that gases will be developed which will put an entire opposing force out of action and yet not injure permanently a man in that force. Not only will development go on inevitably in industry—we could not stop it if we were to try—but every nation will endeavor, in the open or behind closed doors, to continue its research under governmental auspices. No nation will dare take a chance. Poison gases have proved too effective a weapon to be ignored. I should be much discouraged if the army of the United States ceases to experiment in the perfection of gas masks on account of this treaty. The only way to perfect a mask is to experiment with the gases, so the entire research cycle is involved.

"I know I am speaking in contradiction of a very well-defined public sentiment, but nevertheless I think I am justified in making these observations. Can any weapon which in a great war accounts for one-third of all the casualties be definitely and finally barred from use in the wars of the future? It is easy to declare prohibitions against the use of weapons in warfare. The same protest was made against gunpowder many generations ago. I am not enthusiastic about entering into declarations concerning which there is a very strong probability of violation."

Senator Hitchcock of Nebraska made this observation: "While I rather sympathize with the argument of the Senator from New York, I suggest that after all the use of poisonous gases is only in its infancy. If we permit the cultivation and development of the poison gas science, it may be a much more terrific and destructive element in the next war."

Fate of Chemical Warfare Service in Balance—General Staff Favors Continuation as Unit

Decision as to the War Department's policy in the matter of chemical warfare has been vested in a committee of the General Staff. General Fries has made an extended presentation of his views before the committee. In addition, documentary evidence has been submitted. It is believed that it has been established to the satisfaction of the committee that the Chemical Warfare Service should be maintained as a separate entity within the War Department.

The General Staff at one time was very averse to the establishment of a separate Chemical Warfare Service. There was a tendency to minimize the importance of gas in warfare. It is believed, however, that changing personnel, as well as actual developments, has resulted in a very different attitude. A recent poll of officers of the General Staff showed that twenty-two favor the continuance of Chemical Warfare as a separate service, while only two voted to fuse it with Ordnance.

The attention of the Senate Appropriations Committee has been called to the reduction from $1,500,000 to $500,000 in the appropriation for the Chemical Warfare Service during the next fiscal year. It is understood that the Senate committee will make a careful study of the situation. There is reason to entertain hope that the Senate will increase the item.

Consider Calcium Chloride as Dust Preventive

At a meeting in Washington on March 24 of a committee of the American Society for Testing Materials with officials of the Bureau of Public Roads of the Department of Agriculture, to revise specifications for highway materials, a sub-committee was appointed which considered specifications for the use of calcium chloride as a dust preventive on gravel roads.

Large Attendance Expected at New York Convention of Paper Associations

The forty-fifth annual convention of the American Paper and Pulp Association will take place at the Waldorf-Astoria, New York, the week beginning April 10. Several of the meetings of the affiliated associations have been tentatively scheduled, and there is every prospect of a record-breaking attendance.

The dates for the meeting of the American Paper and Pulp Association have been definitely fixed, while the meetings scheduled by the affiliated associations are tentative, but will probably be unchanged in most cases. The list as at present announced follows:

Tuesday, April 11—10 a.m., Glassine and Greaseproof Manufacturers; 10 a.m., Book Paper Manufacturers; 10:30 a.m., Salesmen's Association; 2 p.m., Vegetable Parchment Manufacturers; 2 p.m., Salesmen's Association; 7 p.m., annual banquet of the Salesmen's Association.

Wednesday, April 12—10 a.m., Waxed Paper Manufacturers; 10 a.m., Writing Paper Manufacturers; 2 p.m., Sulphite Bond Division.

Thursday, April 13—10:30 a.m., annual meeting, American Paper and Pulp Association; 7 p.m., annual banquet.

Friday, April 14—11 a.m., Toilet Paper Converters; 2:30 p.m., Tissue Paper Manufacturers; 6 p.m., Tissue Paper Manufacturers and Toilet Paper Converters Association annual dinner. The meetings on Friday are scheduled to take place at the Hotel Astor.

T.A.P.P.I. Program

The seventh annual meeting of the Technical Association will be held in conjunction with the meetings of the American Paper and Pulp Association. The contemplated arrangements are as follows:

Monday, April 10—Meetings of executive committee and standing committees.

Tuesday, April 11—First general session. Reports of officers and committees.

Wednesday, April 12—Second general session. Discussion of committee reports and special papers. Election of officers. Continuation of papers and discussions.

Thursday, April 13—General business meeting, American Paper and Pulp Association. Completion of T.A.P.P.I. program.

Progress of Molding Sand Research Work—Universities and Industries Co-operate

The committee on Molding Sand Research under the guidance of Division of Engineering, National Research Council and American Foundrymen's Association, has made progress in its program of research. The U. S. Geological Survey and the various State Geological Surveys have promised to co-operate with the sub-committee dealing with this phase of the work under the chairmanship of Professor H. Ries, of Cornell University. This sub-committee has prepared a letter of instructions to the State Geological Surveys, which will standardize methods of making the surveys of molding sand resources.

Work on standardization of tests is well under way. Questionnaires have been sent out to gather information on the present methods of testing physical properties of sand. A digest or replies to these questionnaires is expected to be available shortly.

Many firms and universities have offered to co-operate in the research work. Every endeavor will be made to maintain their interest and to assign problems to those universities and industrial laboratories offering to co-operate, due regard being given to the facilities and talent available. A list of research subjects has been compiled, which is given in part below.

1.—Recovery of used molding sand through restoring bond to the sand by subjecting it to contact with water vapor under high pressure.

2.—The effects of additions of certain chemical reagents upon the physical properties of clays and clayey materials, such as molding sand.

3.—Effects of water content on the bond and permeability of a molding sand.

4.—Effects of different water per cents in molding sand on the milling and drilling speeds of light gray iron castings.

5.—Research on fusion quality of facings (function of "peeler").

6.—Tests of various kinds of clays for restoring bond to molding sand.

7.—Comparison of lives of different molding sands.

8.—Effects on plasticity of bond in molding sand and reduction of water content when using oil.

9.—Effects of wet and dry storing of sand on bonding quality.

International Chemical Societies Plan Summer Meetings in France

The third international chemical conference will be held at Lyon, France, June 27 to July 2. At the second congress of the International Association of Pure and Applied Chemistry, the arrangements for the 1922 conference were delegated to the National Federated Chemical Societies of France. The committee of this organization in charge of the plans includes prominent city officials, business men and educators. The general program includes a reception to the delegates by the city of Lyon at the city hall, a number of general meetings, council and committee meetings and a banquet to the delegates given by the Chamber of Commerce of Lyon. A boat trip down the Rhone is also planned. Visits will be made to the silk mills and tanneries in the vicinity of Lyon and to the factories of Jonage.

The last excursions planned will bring the delegates to the vicinity of Marseilles in time to attend the second Congress of Industrial Chemistry to be held in that city July 2 to 7, in the headquarters of the Technical Institute. The arrangements for this meeting are in charge of a committee of prominent business men and industrial chemists of southern France. Among the subjects scheduled for discussion are studies of the mineral resources of the French colonies and studies of fatty acids, soaps, etc. A series of visits to industrial establishments near Marseilles will conclude the program.

International Engineering Conference to Be Held in Rio de Janeiro in September

Plans are being laid for an international engineering congress to be held in Rio de Janeiro in September, 1922, the occasion of the centenary of independence of Brazil.

It is understood that representative engineers from all the American countries will attend the congress and that the principal subjects of discussion will be:

1. The utilization of fuel resources.
2. The best utilization of water power.
3. Recent advances in irrigation methods.
4. The elimination of waste through the standardization of supplies for agricultural and industrial purposes.
5. Coal as a factor in industrial development.
6. Essentials of a national railroad policy.
7. Intercontinental engineering co-operation.
8. Port developments.
9. Terminal facilities.
10. The iron and steel industry.

Exhibition of Technical and Industrial Photography Proposed

A conference for a proposed exhibition of industrial and technical photography will be held in Room 109 of the Waldorf-Astoria Hotel, New York City, April 10, 1922. The meeting is being held during the convention of the American Pulp and Paper Association, as many of the members of that organization are interested in the subject in connection with photomicrographic studies of pulp and paper fibers.

No Interstate Commerce Commission Decision on Reduction of Rates Before April 15

The decision of the Interstate Commerce Commission in the matter of a general reduction in rates, it now appears, will not be forthcoming before April 15. At present the case is being studied by the commissioners individually. If they should find themselves in substantial accord, the decision probably could be handed down as early as April 15, but should there be important differences between them, the time required for the consideration of the case would obviously be extended.

Senate Finance Committee Votes to Extend Dye Embargo

By a vote of 6 to 4 the Senate Finance Committee decided to extend the dye embargo and licensing system for a period of 1 year from the date on which the tariff bill becomes a law. The dye embargo is now authorized under the emergency tariff bill enacted at the last session and continues in effect until a revised tariff bill is passed. At the end of the 1-year period the duties provided in the tariff bill will take effect unless the dyestuff and organic chemical producers are able to convince Congress that the embargo should be continued.

The bill at present provides for 7c. a pound and 50 per cent ad valorem on unfinished dyes and 7c. a pound and 60 per cent ad valorem on finished dyes.

In this connection, however, an emphatic protest has been lodged with the Senate Finance Committee by about 200 smaller manufacturers of synthetic organic chemicals against the extension of the embargo for 1 year only. Their position as communicated to the committee by Dr. S. Isermann is that while 1 year's extension might be helpful to companies with large capital, as they can afford to gamble on future protection, 1 year's extension does not place the smaller manufacturer in a position where he can procure capital to keep his business going.

Russian Engineers Request Technical Publications

The Engineering Section of the Society for Technical Aid to Soviet Russia has been requested by the Russian Scientific and Engineering Societies for contributions of books, bulletins, pamphlets and current literature on the scientific and industrial progress in the United States, particularly since 1914. Individual members of the Society have donated toward a fund created by the engineering group in order to send such literature to Russia. The demand, however, is so great and the needs for the latest available scientific and technical publications are so urgent for Russia's industrial rehabilitation that they cannot be filled by the Engineering Section of the S.T.A.S.R. It is requested that literature of this nature be forwarded to the Engineering Section of the Society for Technical Aid to Soviet Russia, at 110 West 40th St., New York City.

New Chemical Laboratory Is Planned for Tufts College

Bids have been taken for the erection of a new chemical laboratory building at Tufts College, Mass., and work will be commenced on the structure at an early date. The estimated cost has not as yet been announced. Rockwell & Wright, Tufts College, are architects.

Personal

Dr. F. W. Aston of Cambridge University, England, delivered an address on "Isotopes and the Structure of the Atom" before the joint meeting of the Washington Academy of Sciences, Philosophical Society of Washington and the Chemical Society of Washington, March 29, 1922.

William H. Bassett, technical superintendent and metallurgist of the American Brass Co., Waterbury, Conn., a subsidiary of the Anaconda Copper Mining Co., is making a tour of inspection with other officials of the company at the last-named company's properties at Butte, Anaconda and Great Falls, Mont.

A. P. Blackstead, formerly chief engineer of the Camden Iron Works (R. D. Wood & Co.), Camden, N. J., and prior to that hydraulic engineer with the Henry R. Worthington Co., New York, has joined the engineering staff of the Dayton Dowd Co., Quincy, Ill. Mr. Blackstead has recently returned from Europe, where he spent 6 months studying conditions and investigating recent developments in hydraulic engineering.

Dr. Robert P. Calvert addressed the Southern California Section of the American Chemical Society on March 30. He spoke on "The Manufacture of Celluloid and Motion Picture Films."

L. B. Kruse has been elected treasurer and assistant secretary of the Empire Iron Co., Philadelphia, Pa., operated under lease by the Cambria Steel Co., Widener Building, Philadelphia, Pa. P. B. Burtis has been elected secretary and assistant treasurer, succeeding D. B. Gehly, resigned.

Dr. Charles Skeele Palmer, consulting chemical engineer, of Pittsburgh, Pa., and formerly connected with the Mellon Institute, addressed the engineering students of the Carnegie Institute of Technology of Pittsburgh, on March 29, on "Faith in the Order of Nature—Invention Is a Part of It."

O. A. Pickett of the Hercules Powder Co. spoke on "Colloids and Some of Their Applications" before the senior class of the Cooper Union Night School on March 23.

Frederick W. Sperr, Jr., chief chemist of the Koppers Co., Pittsburgh, Pa., has been awarded the Beal medal by the American Gas Association, in recognition of his work and paper, presented at the convention of the organization last November, entitled "The Seaboard Liquid Process of Gas Purification."

A. A. Stevenson, vice-president in charge of manufacture of the Standard Steel Works Co., which is a subsidiary of the Baldwin Locomotive Works, has, at the request of Herbert C. Hoover, been designated a special representative of the American Engineering Standards Committee, to work with the Department of Commerce in the co-operation between the Department's Division of Simplified Practice and the American Engineering Standards Committee.

Dr. E. W. Washburn of the department of ceramics, University of Illinois, will lecture before the Franklin Institute, Philadelphia, on April 6, on the subject "Physical Chemistry and Ceramics."

Obituary

Dr. Theodor Liebisch, late professor of mineralogy at the University of Berlin, died at his home in Berlin, on Feb. 9 after a protracted illness. He was born on April 29, 1852, and from about 1890 to 1900 he was professor of mineralogy at the University of Göttingen. During this period there were very many Americans studying for their degrees in chemistry who took mineralogy under Prof. Liebisch. It is scarcely too much to say that he was one of the most highly respected and best loved professors in the university. He perhaps did more in a personal nature for the American students in those days than any other professor. All Americans respected and admired him for his deep learning, his ability as a teacher, his inspiration for research work and his extremely kind and ever thoughtful nature. About the year 1900 he was called to the University of Berlin, and served there until about 1920, when he retired from active work. He was the author of many books, his most important being "Grundriss der Physikalischen Krystallographie."

Market Conditions

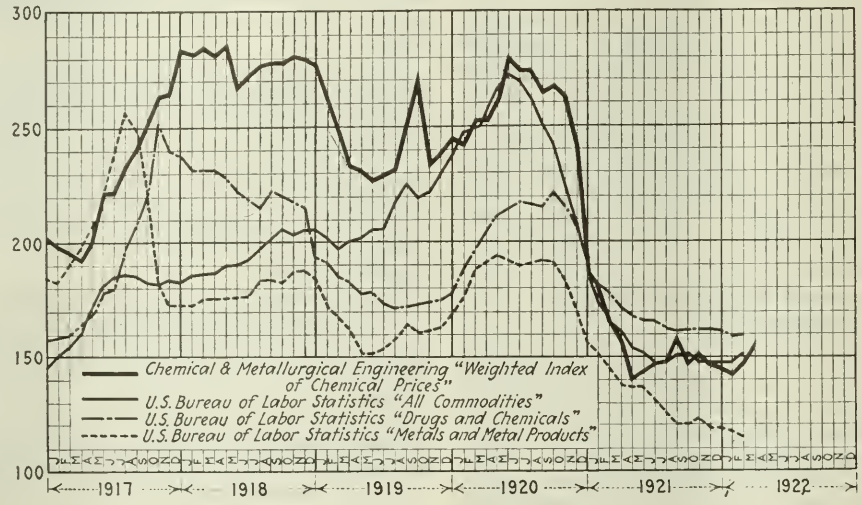
IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Business Progress During March

It is often said that the trend of business during the first 3 months of the calendar year affords a reliable index of conditions to be expected in the remaining three quarters. If this be the case, certainly there is much to justify the restoration of industrial confidence. The worst of the period of business readjustment is now so definitely behind us that current historians are already beginning to refer to the "memorable depression of 1921."

Many of the factors of improvement noted in the underlying business conditions in the early months of the year are becoming better defined and their influence on business is now more apparent. Among these factors, or the conditions directly attributable to them, are included the following: (1) The upward turn in certain commodity prices, notably farm products and foodstuffs, has not only increased the purchasing power of the farmer but has helped to close up the unduly wide spread between producer and consumer prices. (2) The larger volume of production, particularly in the iron and steel industry, but also noted in the manufacture of paper, petroleum, and other basic commodities, has materially lessened unemployment. (3) The strengthening advance in the stock market and the coincident easing up of money rates are signs of returning confidence in the future of business. (4) The recent increase in car loadings are indicative of greater industrial activity, especially as regards consumption and distribution. (5) The progress being made toward lower costs and increased efficiency promises a healthier form of competition.



COMPARISON OF WHOLESALE PRICES, 1917-1922

The only clouds on the business horizon are the difficult problems now being solved in the coal mines of the country and in the New England textile mills. The textile strike, although in progress for over 10 weeks, is still at a deadlock. The mill owners are meeting serious obstacles in their attempts to lower costs and to get their industry on a basis to compete with the Southern mills, where wage reductions have already been accepted. The coal strike, involving 600,000 men in both hard and soft coal mines, has not as yet caused a great deal of anxiety among our industrial leaders—in fact, many feel that if the general walkout had to come, there could have been no more appropriate time. The Geological Survey has announced that on March 1 the general industrial consumers had on hand an average coal reserve of 56 days, electric utilities 54 days, steel plants 48 days, railroads 42 days and byproduct coke ovens 39 days. It was officially estimated that the reserve on April 1 was 63 million tons and that production at the non-union bituminous mines of the country would continue at the rate of 4,700,000 tons per week.

Of the favorable factors listed in a previous paragraph, perhaps the one most welcomed by the manufacturer has been the gain in wholesale prices. That the chemical and related industries have participated in this upward movement is clearly shown in the accompanying chart. During the last 2 months the CHEM. & MET. index number has risen approximately 14 points and during the month of March has averaged 156.19, the highest quotation since August, 1921.

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

This week	156.75
Last week	157.65
April, 1917	207
April, 1918 (high)	286
April, 1920	261
April, 1921 (low)	140

This index number is based on the wholesale prices in the New York market for acetic acid, citric acid, hydrochloric acid, nitric acid, sulphuric acid, ethyl alcohol, methanol, anhydrous ammonia, ammonium sulphate, barium chloride, bleaching powder, borax, caustic potash, caustic soda, copper sulphate, formaldehyde, glycerine, potassium carbonate, saltcake, soda ash, crude sulphur, benzene, aniline oil, cottonseed oil and linseed oil.

The Financial Situation

In the face of the adverse financial statements and the losses or lowered earnings noted in the annual reports of many companies, the stock market has maintained an unusually strong position. Since August of last year the *Annalist's* average for twenty-five industrials has shown an advance of 18 points. A similar average based on the stocks of twenty chemically controlled industries has also gained considerably during this period. From 46.1 on Aug. 1, 1921, this average rose to 59.0 on March 1. The ascent during the past month has continued, although at a somewhat slower rate. The increased activity in stocks can be attributed largely to the comparative ease in the money market. Call money in New York on March 18 got down to 2½ per cent, the lowest figure reached in recent years. Since then there has been a reaction, to be sure, and by the end of the month the rate was up to 4½@5 per cent. It is also interesting to record that on March 18 more separate stock issues were sold on the New York Stock Exchange during the day's business than on any other day in its history. For several days the number of shares handled exceeded a million.

A discussion of the financial market, however, is not complete without a reference to developments in the foreign exchanges. As the month started, sterling stood at the highest level since 1918. The quotation on March 1 was $4.44⅜. Toward the middle of the month and coincident with our demands on the Reparations Commission and the cessation of gold exports from London, the rate fell to $4.34. Since then there has been a slight recovery, bringing the value of the pound back to $4.37 on March 31. The sensation of the foreign exchange market, however, has been the sudden break in the German mark, which on March 27 had fallen to $0.0028⅝. This is the lowest quotation ever recorded for this currency and is generally believed to have resulted from the announcement of more stringent reparation policies on the part of the Allies.

The Chemical Market During the First Quarter of 1922

Developments of the first months of the current year have done much to encourage the growing feeling of optimism among the large producers and consumers of chemicals. The readjustments made throughout January were largely responsible for the general upward turn in prices which began in February and continued during the past month. The return to normal has not been entirely completed, but the process has left the chemical market in a much healthier condition than at any time in the past 2 years.

One of the outstanding features of the market during the last few months has been the recovery in the price of caustic soda—long regarded as the barometer of trading in the chemical industries. Domestic consumers, together with the foreign buyers, have forced the price of caustic from $3.25 per 100 lb. in February to $3.70 for 100 lb. in March. This has given an added impetus to the rest of the list, as may be noted from the accompanying tabulation of chemical prices. Large producers of caustic have been sold up until June, and in all probability the market will reach 4c. per lb. in the very near future. Other features have been the remarkable rise in barium chloride, prussiates of soda and potash, and sulphate of ammonia. Barium chloride opened the year at $52 per ton, recorded a decline in January to the extent of $4 per ton, but has steadily advanced since February from $50 to the present high level of $82 per ton for available spot material. Domestic producers are strongly of the belief that the market will reach $100 per ton before the summer months. Prussiate of soda has followed practically the same lines as barium chloride. Opening 1922 at 16½c. per lb., it recorded a steady advance throughout January and February. The first 2 weeks of March brought this commodity to a new high level of 18½c. per lb., but during the latter part of March the market declined slightly to 17c. per lb. Yellow prussiate of potash recorded a noteworthy advance since the beginning of the year. Opening at 23c. per lb., it continued to rise throughout the quarter and on March 31 was quoted at 26c. per lb. Stocks have gradually diminished on spot and imported goods have been difficult to locate. Domestic manufacturers report a sold-up condition for the next few months. It remained for the red prussiate, however, to show the greatest advance in the entire list. Prices quoted during the month of January were around 30c. per lb., but it has since become practically nominal, with only a barrel noted here and there at 70c. per lb. Dealers in sulphate of ammonia profited by large tonnage orders from Europe and Japan. The rise in this commodity did not take place until the latter part of February. It has since continued to advance, with quotations for limited supplies around $3.50 per 100 lb. Producers claim that the present market prices are not sufficient to net any substantial profits. There is no doubt that a higher market will be seen for this commodity in the near future. On the other hand, the quarter recorded a number of declines. Among them were formaldehyde, oxalic acid, glaubers salt, bleaching powder and cyanide of soda. In most cases these declines followed readjustments of costs, although some were the result of competition between domestic producers and importers. Bleaching powder manufacturers have also been hard pressed by importers, who have brought in large shipments of this material at extremely low figures. The result was that domestic bleach has declined since January to almost pre-war prices. The lower quotations for oxalic acid were the result of price-cutting among the domestic producers. This has caused a drop of 3c. per lb. since Jan. 1. Formaldehyde, cyanide of soda, fusel oil, granular zinc chloride, lead acetate, acetic acid and methanol were reduced by domestic manufacturers either to attract new business or to meet quotations on foreign materials.

A QUARTERLY REVIEW OF THE PRICES OF 45 IMPORTANT CHEMICALS, JANUARY–APRIL, 1922

Article	Unit	Price on Jan. 1	Average for Month of Jan.	Feb.	March	Price on April 1
Acetic acid, glacial	Lb.	$0.10	$0.10	$0.09	$0.09	$0.09
Muriatic acid, 20 deg.	100 lb.	1.25	1.25	1.15	1.15	1.10
Nitric acid, 40 deg.	Lb.	.06½	.06¼	.06¼	.06¼	.06
Oxalic acid	Lb.	.14½	.14	.14	.11¾	.11½
Sulphuric acid, 66 deg.	Ton	17.00	16.50	16.00	16.00	17.00
Acetate of lead	Lb.	.10⅝	.10⅝	.10⅝	.09⅝	.09⅝
Ammonia alum, lump	Lb.	.03½	.03½	.03½	.03½	.03½
Aluminum sulphate, iron free	Lb.	.02½	.02½	.02½	.02½	.02½
Sal ammoniac, white gran	Lb.	.07	.06¾	.06¾	.07	.07¼
Ammonium sulphate	Lb.	.02⅝	.02⅝	.02½	.03¼	.03½
Amyl acetate	Gal.	2.40	2.00	2.00	2.00	2.00
Arsenic, white powd.	Lb.	.06	.07	.07¼	.07¼	.07
Barium chloride	Ton	52.00	50.00	56.00	75.00	80.00
Bleaching powder	100 lb.	2.50	2.25	2.10	1.75	1.60
Calcium acetate	100 lb.	1.75	1.75	1.75	1.75	1.75
Camphor	Lb.	.91	.90	.92	.90	.89
Copperas	Ton	15.00	15.00	15.00	15.00	15.00
Copper sulphate, crystals	100 lb.	5.65	5.65	5.60	5.55	5.55
Epsom salts, U.S.P.	100 lb.	2.65	2.65	2.65	2.60	2.50
Formaldehyde, 40%	Lb.	.10½	.10½	.10	.08½	.08½
Fusel oil, refined	Gal.	2.50	2.50	2.50	2.50	2.50
Glaubers salt	100 lb.	1.30	1.25	1.15	1.00	.95
Glycerine, c.p.	Lb.	.16	.16½	.16½	.16	.15½
Methanol, 95%	Gal.	.62	.61	.59	.58	.58
Nickel salt, single	Lb.	.14	.12	.11	.11	.11
Phosphorus, red	Lb.	.45	.45	.45	.45	.45
Potassium bichromate	Lb.	.10½	.10½	.10⅝	.10⅝	.10⅝
Potassium bromide, gran.	Lb.	.15	.14	.13½	.18	.17
Carbonate of potash, 80-85%	Lb.	.04½	.04½	.04½	.04½	.04½
Chlorate potash, crystals	Lb.	.06	.05½	.05½	.05¾	.06½
Caustic potash, 88-92%	100 lb.	5.50	6.00	5.75	6.00	6.00
Permanganate of potash, U.S.P.	Lb.	.16	.14	.13½	.15	.15
Prussiate of potash, yellow	Lb.	.23	.25	.25	.26	.26
Salt cake, bulk	Ton	18.00	17.00	17.00	17.00	17.00
Soda ash, light, 58%	100 lb.	1.80	1.75	1.70	1.80	1.80
Bichromate of soda	Lb.	.07⅝	.07½	.07¾	.07½	.07½
Fluoride of soda	Lb.	.11	.10½	.09½	.09½	.09½
Cyanide of soda	Lb.	.27	.26	.23½	.23½	.22½
Caustic soda, solid	100 lb.	3.75	3.70	3.35	3.65	3.65

The New York Market

NEW YORK, April 2, 1922.

The general condition of the chemical market during the past week was fairly steady, although several dealers reported a slight improvement in the volume of business. Both advances and declines were noted in some of the more important items. Consumers have found some difficulty in obtaining certain chemicals, while for other commodities the market seemed oversupplied. The markets for barium chloride, caustic soda, sulphide of soda and sulphate of ammonia continued their recent activity and remained exceptionally strong. Caustic soda has attracted considerable attention. Consumers in Germany, Italy and Japan are sending inquiries for this material, and leading producers are quite firm in the belief that a much higher market will be seen in the very near future. Bleaching powder, on the other hand, has been somewhat notably weak. Barium chloride is maintaining its recent rise, with spot offerings relatively light.

General Chemicals

Barium Chloride.—Sellers quote the market exceedingly firm at $82 per ton on spot and $70 to arrive. Spot material is very scarce and dealers are not free in their offerings. Cables from abroad have been an important factor in the recent sharp advance.

Bichromate of Soda.—The market has shown very little signs of real live trading. Quotations are heard at 7½@7¾c. per lb., according to quantity.

Caustic Potash.—The market for this product showed considerable strength early in the week, but later slackened because of lack of interest on the part of the consumers. Although most quotations were around 6c. per lb., odd lots were recorded down to $5.65 per 100 lb.

Caustic Soda.—No real change of any importance was heard in this item during the week and the general condition of the market was reported fair. Resale lots were quoted at $3.65 per 100 lb. f.a.s. N. Y., for March-April shipment. Some producers reported their entire output sold until June. Quotations at the works are unchanged at 2½c. per lb., basis 60 per cent, on contracts in carload lots.

Chlorate of Potash.—Imported goods were quoted somewhat higher by leading sellers and late in the week 6½c. per lb. was named as the general quotation. Some sales were recorded a fraction below this figure. Domestic chlorate remained unchanged at 8c. per lb., f.o.b. works.

Chlorate of Soda.—Imported material is held firm at 6½@6¾c. per lb. Surplus stocks have disappeared to a noticeable extent and sellers are not eager to quote below these figures. Domestic quotations remain unchanged at 7c. per lb., f.o.b. works.

Bleaching Powder.—Another reduction was recorded in this item at producing quarters and first hands are quoting down to $1.60 per 100 lb., f.o.b. works, in large drums. Imported bleach is quoted at $1.85 per lb., ex-dock N. Y. The demand has not been active since large consumers covered their contract requirements.

Hydrochloric Acid.—A fair movement of this material into consuming channels is reported. Offerings, however, have been quite free of late. The best prices heard for the 18 deg. goods is $1.10 per 100 lb.

Sulphuric Acid.—There has been a decided change in this material among leading sellers and prices have been advanced to $17@$17.50 per ton for the 66 deg. goods in tank cars. The 60 deg. test is quoted at $11@$12 per ton. Contract requirements can be obtained at about $1 per ton under the regular quotations.

Linseed Oil

Linseed Oil.—Following a decline in Argentine flaxseed, the market on linseed oil was easier. Crushers lowered prices to a basis of 78c. per gal. in carload lots. The inquiry for shipment oil over the next 3 months has improved, but buyers were unwilling to pay any high figures and little business was transacted. The tariff situation attracted a good deal of attention. It is believed that the new duty will be 3c. per lb., equal to 22c. per gal. Imported oil was offered at 71c. per gal. for English material, April shipment, duty paid.

The St. Louis Market

ST. LOUIS, March 30, 1922.

While some of the present activities in the heavy industrial chemical market could be traced directly to the fear of the impending coal strike, we do not believe this to be entirely responsible, but that depleted stocks, resumption of industrial activities, firmness of prices and restoration of confidence are primarily the influencing factors. Statistics indicate that all industries have made an appreciable increase in their operations, some to the extent of 25 to 50 per cent. Price changes have been very few, with declines in the minority, and in general prices are much firmer than they have been for many months. Further, the market is practically devoid of any depressing selling pressure. Heavy importations are still reported, but at greatly enhanced prices, due to the continued rise in exchange, thus showing no demoralizing effect upon the market.

Alkalis

Caustic soda maintains the same price of 2 weeks ago and is moving in good volume to small buyers. Very little carload business being done. *Soda ash* is firm at $2.50 per 100 lb. in barrels and $2.30@$2.40 per 100 lb. in bags—this for less than carload lots. Carloads can be had for ¾c. under these prices. *Sodium bicarbonate* is moving slowly with no price variations. *Sal soda* is steady and in good demand at the prevailing price of last week.

General and Special Chemicals

The *heavy mineral acid* market is no longer being disturbed by the weak holders, who some time ago were willing to unload at very little or nothing, consequently there has been better interest and firmer prices. Furthermore, the acid market has been greatly benefited by the increased operations of the steel mills and many other large industrial plants where acids are required. *Citric acid* has shown more life during the past few weeks with a firm market. *White arsenic* is now on the easier side and spot lots are quoted at 6@7½c. per lb., f.o.b. producer's works. *Benzene* is moving in good volume with the market in producers' hands. Ruling prices are 37@40c. per gal. *Bromides* are very firm with a good demand. *Carbon bisulphide* has been rather quiet, prices remaining the same. There has been no change in price of *carbon tetrachloride*, and trading did not deviate from the routine. While the *copperas* demand is still beyond production, conditions have eased to some extent owing to the fact that during the past 60 days the steel mills have been operating more extensively. Prices quoted by one manufacturer for granular in bulk are 90c. per 100 lb. by the carload, and for the *flour copperas* $1.80 per 100 lb. in carload lots and $1.90 per 100 lb. in less than carload lots, all prices f.o.b. producer's works. *Epsom salts* has firmed up considerably, prices ranging from $2.70@$2.87½ per 100 lb. for less than carload lots, supplier's warehouse. *Glycerine* has not changed in price, though the demand has slackened a bit and 16c. is being asked by all producers, but one or two transactions have been made recently at 15½c. *Sulphur* is moving in good volume and maintaining a good steady price. *Zinc sulphate technical* has been rather quiet since our last report, prices, however, prevailing the same.

Vegetable Oils and Naval Stores

Castor oil retains its standing in the price list at 13¼c. in drums, and a commission of 1c. is being made to customers purchasing quantities of 200 gal. or more. *Linseed oil* is quoted today at 84c. basis raw oil, a decline of 3c. since our last report. *Turpentine* is quoted at 89½c., a variation of ½c. since last report.

Paint Materials

Red oxides remain stable and in fairly good demand. *Whiting* ranges in price from $11@$15 per ton, depending on quality and brand. Domestic *lithopone* is moving in fair volume at 6½c. in preference to imported goods at 6c.

The *barytes* market is about $23 per ton for high-grade material.

The Iron and Steel Market

PITTSBURGH, March 31, 1922.

There is an upward swing in prices in the iron and steel industry, manifested by actual advances in market prices for some commodities and by a stiffening in others. The disposition among sellers to advance prices is general and the opportunity is embraced as rapidly as it presents itself. Among buyers a disposition to buy seems equally manifest.

Bars and shapes are now fairly quotable at 1.50c., against 1.40c. a week ago and 1.35c. about 3 weeks ago. A price of 1.50c. is not rigidly maintained, as some particularly desirable orders have been going at less, while small orders have brought 1.55c. and in occasional instances 1.60c.

Hoops and hot-rolled strips are up $2 a ton, being quite firm at 1.90c. Wire nails continue very firm at $2.40, while price concessions in tubular goods are less extensive.

Many of the sheet mills have in the past 10 days announced that on April 1 their prices would be advanced $3 a ton, to 3.15c. for black sheets, 4.15c. for galvanized and 4.50c. for automobile sheets. There seems to be no doubt that within a few days all makers will have advanced prices.

There is no uncertainty as to the amount of buying that has occurred, the rate of production, the prices, the volume of shipments or payment for the shipments made. The buying has been heavy, production of ingots has increased from a rate under 18,000,000 tons a year at the end of December to a rate of about 29,000,000 tons at the end of February and to a rate of probably 31,000,000 or 32,000,000 tons at the present time. Substantially all the steel made has been shipped. Prices have been firming up, with some advances, and more advances are probable.

UNCERTAINTY AS TO ACTUAL CONSUMPTION

These things are well established, yet there is uncertainty as to the future, whether demand and production will continue to increase or will soon begin to decrease. The uncertainty lies in the relation between steel received by buyers and steel passing into actual consumption. Experienced observers are a unit in declaring that ultimate consumption is well below the rate of producing and shipping. Perhaps the condition resembles that which has obtained at certain times in the past, when demand exceeded consumption through buyers replenishing stocks and afterward consumption rose so as to balance production, the increase in stocks having been necessary to provide facilities for jobbers and manufacturing consumers to conduct their business in an orderly and efficient manner.

A particular element of uncertainty is injected into the situation by the fact that at midnight tonight begins the coal-mining suspension. The suspension promises to be a very serious affair, yet the current estimates are that consumers of coal have well fortified themselves. If one assumes that buyers of steel have been influenced by the prospective mining suspension to lay in stocks of steel, then there is a possibility of demand decreasing once the suspension has begun.

Producers of steel are particularly keen to make the most of their limited opportunites in advancing prices. Before the war it was held that steel prices were unlikely to advance except with the steel industry operating at 80 or 85 per cent of its capacity. At 32,000,000 tons of ingots a year the nominal operating rate would be a trifle over 60 per cent, but counting out some capacity that cannot be reckoned when prices are so extremely low, the practical operating rate is probably nearer 70 per cent.

COKE AND PIG IRON

Connellsville coke has weakened somewhat, it being possible to pick up odd lots of spot furnace coke at $3.25, though for regular shipment over a week or two last week's price of $3.50 would probably have to be paid. Connellsville coal has gone to remarkably low levels, well below cost of production with the Frick scale. A number of operators have been paying less than the scale, and it is far from impossible that strikes will occur at such mines.

Pig iron shows a stronger tone, but with prices still quotable at $19.50 for bessemer, $18 for basic and $19 for foundry, f.o.b. valley furnaces, freight to Pittsburgh being $1.96.

Sodium prussiate, yellow	lb.	.17 – .17¼	.17½ – .17¾
Sodium silicate, solution (40 deg.)	100 lb.	.85 – 1.00	1.05 – 1.15
Sodium silicate, solution (60 deg.)	100 lb.	2.50 – 2.60	2.65 – 3.00
Sodium sulphate, crystals (glaubers salt)	100 lbs.	.95 – 1.10	1.15 – 1.50
Sodium sulphide, fused, 60-62 per cent (conc.)	lb.	.04¾ – .04½	.04¾ – .05½
Sodium sulphite, crystals	lb.	.03½ – .03⅝	.03¾ – .04¼
Strontium nitrate, powdered	lb.	.10 – .11	.11½ – .15
Sulphur chloride, yellow	lb.	.04½ – .05	.05¼ – .06
Sulphur, crude	ton	18 00 –20.00	..... – .....
Sulphur dioxide, liquid, cylinders extra	lb.	.08 – .08½	.09 – .10
Sulphur (sublimed), flour	100 lb.	..... –	2.25 – 3.10
Sulphur, roll (brimstone)	100 lb.	..... –	2.00 – 2.75
Talc—imported	ton	30 00 –40 00	..... – .....
Talc—domestic powdered	ton	18 00 –25 00	..... – .....
Tin bichloride	lb.	.09 – .09¼	.09½ – .10
Tin oxide	lb.	..... –	.37 – .38
Zinc carbonate	lb.	.14 – .14½	.14¾ – .15½
Zinc chloride, gran.	lb.	.05½ – .06	.06¼ – .06¾
Zinc cyanide	lb.	.42 – .44	.45 – .47
Zinc oxide, XX	lb.	.07½ – .08	.08¼ – .08½
Zinc sulphate	100 lb.	2 75 – 3.00	3.05 – 3.30

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.30 — .31
Aniline oil, drums extra	lb.	.16½ — .17
Aniline salts	lb.	.24 — .26
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.25 — 1.30
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.75 — .85
Benzoic acid, U.S.P.	lb.	.60 — .65
Benzoate of soda, U.S.P.	lb.	.55 — .57
Benzene, pure, water-white, in drums (100 gal.)	gal.	.29 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.27 — .32
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech.	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.60 — .65
Beta-naphthol, tech	lb.	.28 — .30
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97–99%, straw color, in drums	gal.	.50 — .52
Cresylic acid, 95-97%, dark, in drums	gal.	.45 — .47
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	1.15 — 1.20
Dimethylaniline	lb.	.38 — .40
Dinitrobenzene	lb.	.23 — .25
Dinitroclorbenzene	lb.	.23 — .25
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.33 — .35
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Diphenylamine	lb.	.59 — .70
H-acid	lb.	.85 — 1.00
Meta-phenylenediamine	lb.	.90 — 1.00
Monochlorbenzene	lb.	.14 — .15
Monoethylaniline	lb.	1.20 — 1.25
Naphthalene crushed, in bbls.	lb.	.06 — .06½
Naphthalene, flake	lb.	.06½ — .07
Naphthalene, balls	lb.	.08 — .08½
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17½
Ortho-amidophenol	lb.	2.75 — 2.80
Ortho-dichlor-benzene	lb.	.15 — .20
Ortho-nitro-phenol	lb.	.75 — .80
Ortho-nitro-toluene	lb.	.12 — .15
Ortho-toluidine	lb.	.16 — .20
Para-amidophenol, base	lb.	1.25 — 1.30
Para-amidophenol, HCl	lb.	1.30 — 1.35
Para-dichlorbenzene	lb.	.15 — 18
Paranitroaniline	lb.	.75 — .77
Para-nitrotoluene	lb.	.70 — 75
Para-phenylenediamine	lb.	1.50 — 1.55
Para-toluidine	lb.	1.10 — 1.15
Phthalic anhydride	lb.	.35 — .38
Phenol, U. S. P., drums	lb.	.11½ — 15
Pyridine	gal.	1.75 — 2.75
Resorcinol, technical	lb.	1.30 — 1.35
Resorcinol, pure	lb.	1.75 — 1.80
Salicylic acid, tech., in bbls.	lb.	.23 — .24
Salicylic acid, U. S. P.	lb.	.25 — .26
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.25 — .28
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.10 — .12
Sulphanilic acid, crude	lb.	.25 — .27
Tolidine	lb.	1.20 — 1.30
Toluidine, mixed	lb.	.32 — .38
Toluene, in tank cars	gal.	.25 — 28
Toluene, in drums	gal.	.30 — .35
Xylidines, drums, 100 gal.	lb.	.40 — .45
Xylene, pure, in drums	gal.	.40 — .45
Xylene, pure, in tank cars	gal.	.45 — .....
Xylene, commercial, in drums, 100 gal.	gal.	.33 — .35
Xylene, commercial, in tank cars	gal.	.30 — .....

Waxes

Prices based on original packages in large quantities.

Bayberry Wax	lb.	$0.20 — $0.21
Beeswax, refined, dark	lb.	.26 — .28
Beeswax, refined, light	lb.	.30 — .32
Beeswax, white pure	lb.	.35 — .40
Candellila, wax	lb.	.25 — .26
Carnauba, No. 1	lb.	.45 — .46
Carnauba No. 2, North Country	lb.	.25 — .25½
Carnauba, No. 3, North Country	lb.	.16 — .16½
Japan	lb.	.17½ — .18
Montan, crude	lb.	.04½ — .04½
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.04½ — .04½
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.02⅜ — .....
Paraffine waxes, refined, 118-120 m.p.	lb.	.03 — .03½
Paraffine waxes, refined, 125 m.p.	lb.	.03½ — .03¾
Paraffine waxes, refined, 128-130 m.p.	lb.	.04 — .04½
Paraffine waxes, refined, 133-135 m.p.	lb.	.04½ — .04¾
Paraffine waxes, refined, 135-137 m.p.	lb.	.05 — .05¼
Stearic acid, single pressed	lb.	.08¾ — .09
Stearic acid, double pressed	lb.	.09¼ — .09½
Stearic acid, triple pressed	lb.	.10¼ — .10½

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl.	280 lb.	$5.15 —	5.20
Rosin E-I	280 lb.	5.25 —	5.30
Rosin K-N	280 lb.	5.90 —	6.65
Rosin W. G.-W. W.	280 lb.	7.00 —	7.25
Wood rosin, bbl.	280 lb.	6.25 —	.....
Spirits of turpentine	gal.	.86½ —	.87
Wood turpentine, steam dist	gal.	.84 —	.....
Wood turpentine, dest. dist.	gal.	.68 —	.70
Pine tar pitch, bbl.	200 lb.	..... —	6.00
Tar, kiln burned, bbl. (500 lb.)	bbl.	..... —	9.50
Retort tar, bbl.	500 lb.	—	9.00
Rosin oil, first run	gal.	.36 —	.....
Rosin oil, second run	gal.	.38 —	.....
Rosin oil, third run	gal.	.46 —	.....
Pine oil, steam dist., sp.gr., 0.930-0.940	gal.		$1.90
Pine oil, pure, dest. dist.	gal.		1.50
Pine tar oil, ref., sp.gr. 1.025-1.035	gal.		.46
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.		.35
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.		.75
Pine tar, ref., thin, sp.gr., 1.080-1.960	gal.		.35
Turpentine, crude, sp. gr., 0.900-0.970	gal.		1.25
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990	gal.		.35
Pinewood creosote, ref.	gal.		.52

Fertilizers

Ammonium sulphate, f.a.s., N.Y.	100 lb.	3.50 —	3.75
Blood, dried, f.o.b., N. Y.	unit	4.00	
Bone, 3 and 50, ground, raw	ton	30.00 —	32.00
Fish scrap, dom., dried, f.o.b. works	unit	3.10 —	3.20
Nitrate soda	100 lb.	2.85 —	2.87½
Tankage, high grade, f.o.b. Chicago	unit	3.25 —	3.40
Phosphate rock, f.o.b. mines, Florida pebble, 68-72%	ton	5.50 —	7.00
Tennessee, 78-80%	ton	8.50 —	9.00
Potassium muriate, 80%	ton	33.50 —	35.00
Potassium sulphate	unit	1.00 —	.....

Crude Rubber

Para—Upriver fine	lb.	$0.17½ —	.17¾
Upriver coarse	lb.	.12 —	.13
Upriver caucho ball	lb.	.12½ —	.13
Plantation—First latex crepe	lb.	.14¾ —	.15
Ribbed smoked sheets	lb.	.14½ —	.15
Brown crepe, thin, clean	lb.	.13 —	...
Amber crepe No. 1	lb.	.15 —	....

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls.	lb.	$0.10 —	$0.10½
Castor oil, AA, in bbls.	lb.	.11½ —	.12
China wood oil, in bbls.	lb.	.14 —	.14½
Coconut oil, Ceylon grade, in bbls	lb.	.08½ —	.09
Coconut oil, Cochin grade, in bbls.	lb.	.09½ —	.09¾
Corn oil, crude, in bbls.	lb.	.11¼ —	.11½

Cottonseed oil, crude (f. o. b. mill)	lb.	09½ —	10
Cottonseed oil, summer yellow	lb.	11½ —	12
Cottonseed oil, winter yellow	lb.	13½ —	13¾
Linseed oil, raw, car lots (domestic)	gal.	78 —	79
Linseed oil, raw, tank cars (domestic)	gal.	74 —	75
Linseed oil, in 5-bbl lots (domestic)	gal.	81 —	82
Olive oil, denatured	gal.	1 12 —	1 15
Palm, Lagos	lb.	.08 —	.08¼
Palm, Niger	lb.	.06¾ —	06¾
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.10 —	.10¼
Peanut oil, refined, in bbls	lb.	.12 —	.13
Rapeseed oil, refined in bbls	gal.	.85 —	85
Rapeseed oil, blown, in bbls	gal.	.87 —	88
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.11 —	
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.09¼ —	

FISH

Light pressed menhaden	gal.	$0 54 —	
Yellow bleached menhaden	gal.	57 —	
White bleached menhaden	gal.	.56 —	
Brown menhaden	gal.	.61 —	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Asbestos, crude No. 1, f.o.b., Quebec, Canada	short ton	$800 00	$1,000.00
Asbestos, shingle stock, f.o.b., Quebec, Canada	short ton	70 00	—120 00
Asbestos, cement stock, f.o.b., Quebec, Canada	short ton	12 50	— 17 50
Barytes, ground, white, f.o.b. mills	net ton	17.00	— 23 00
Barytes, ground, off color f.o.b. mills	net ton	13.00	— 21 00
Barytes, floated, f.o.b. St. Louis	net ton	23.00	— 24 00
Barytes, crude f.o.b. mines	net ton	6.00	— 7.00
Casein	lb.	.10½	— .12
China clay (kaolin) crude, f.o.b. mines, Georgia	net ton	6.00	— 8.00
China clay (kaolin) washed, f.o.b. Georgia	net ton	8.00	— 10.00
China clay (kaolin) powdered, f.o.b. Georgia	net ton	12.00	— 20.00
China clay (kaolin) crude f.o.b. Virginia points	net ton	8.00	— 12.00
China clay (kaolin) ground, f.o.b. Virginia points	net ton	13 00	— 20.00
China clay (kaolin), imported, lump	net ton	14.00	— 20.00
China clay (kaolin), imported, powdered	net ton	30.00	— 35.00
Feldspar, No. 1 pottery grade	long ton	6.50	— 6.75
Feldspar, No. 2 pottery grade	long ton	5.75	— 5.90
Feldspar, No. 1 soap grade	long ton	7 25	— 7 50
Feldspar, No. 1 Canadian, for mill	long ton	22 00	— 22 50
Graphite, Ceylon lump, first quality	lb.	.04½	— 06½
Graphite, Ceylon chip	b.	.03½	— .05
Graphite, high grade amorphous crude	lb.	.00½	— .02½
Kieselguhr, f.o.b. mines, Cal.	per ton	40.00	—
Kieselguhr, f.o.b. N. Y.	per ton	55.00	— 60.00
Magnesite, calcined (crude)	per ton	12.00	— 15.00
Pumice stone, imported	lb.	.03	— .40
Pumice stone, domestic, lump	lb.	.05	— .05½
Pumice stone, domestic, ground	lb.	.06	— .07
Shellac, orange fine	lb.	86	— .87
Shellac, orange superfine	lb.	.88	— .89
Shellac, A. C. garnet	lb.	.68	— .69
Shellac, T. N.	lb.	.83	— .84
Silica, glass sand, f.o.b. Indiana	per ton	1.25	— 1.50
Silica, sand blast material, f.o.b. Indiana	per ton	2.25	— 4.50
Silica, amorphous, 250 mesh, f.o.b. Illinois	per ton	14.00	— 14.50
Silica, building sand, f.o b. Pa	per ton	2.25	— 3.00
Soapstone	ton	12.00	— 15.00
Talc, 200 mesh, f.o.b. Vermont	ton	7.00	— 12.00
Talc, 200 mesh, f.o.b. Georgia	ton	8.25	— 13.00
Talc, 200 mesh, f.o.b. Los Angeles	ton	16.00	— 20.00

Refractories

Bauxite brick, 56% Al, f.o.b. Pittsburgh	per 1,000	$130.00
Carborundum refractory brick, 9-in.	1,000	1100.00
Chrome brick, f.o.b. Eastern shipping points	net ton	41–44
Chrome cement, 40-50% Cr_2O_3	net ton	30–32
Chrome cement, 40-45% Cr_2O_3, sacks, in car lots, f.o.b. Eastern shipping points	net ton	30–32
Fireclay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works	1,000	32–37
Fireclay brick, 2nd quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works	1,000	27–30
Magnesite brick, 9-in. straight (f.o b. works)	net ton	53–55
Magnesite brick, 9-in. arches, wedges and keys	net ton	70
Magnesite brick, soaps and splits	net ton	90
Silica brick, 9-in. sizes, f.o.b. Chicago district	1,000	35–37
Silica brick, 9-in. sizes, f.o.b. Birmingham district	1,000	37–39
Silica brick, 9-in. sizes, f.o.b. Mt. Union, Pa.	1,000	27–30

Ferro-Alloys

All f.o.b. Works

Ferrocarbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200.00 —	$225.00
Ferrochromium, per lb. of Cr contained, 6–8% carbon, carlots	lb.	.11 —	
Ferrochromium, per lb. of Cr contained, 4-6% carbon, carlots	lb.	.11½ —	
Ferromanganese, 76-80% Mn, domestic	gross ton	62.50 —	
Ferromanganese, 78-82% Mn, English and German c. i.f. Atlantic seaport	gross ton	59 00 —	62.50
Spiegeleisen, 18-22% Mn	gross ton	30 00 —	32.00
Ferromolybdenum, 50-60% Mo, per lb. of Mo	lb.	2.00 —	2.25
Ferrosilicon, 10-15%	gross ton	38.00 —	40.00
Ferrosilicon, 50%	gross ton	54.00 —	55.00
Ferrosilicon, 75%	gross ton	115.00 —	120.00
Ferrotungsten, 70-80%, per lb. of contained W	lb.	.37 —	.50
Ferro-uranium, 35-50% of U, per lb. of U content	lb.	6.00 —	
Ferrovanadium, 30-40% per lb. of contained V.	lb.	3.55 —	3.75

Ores and Semi-finished Products

All f.o.b. New York, Unless Otherwise Stated

Bauxite, 52% Al content	net ton	$6 00 —	$12 00
Chrome ore, Calif concentrates, 50% min Cr_2O_3	t	19 00 —	20 00
Chrome ore, 50% Cr_2O_3, f.o.b. Atlantic seaboard	to	19 00 —	20 00
Coke, foundry, f.o.b. ovens	net ton	4 25 —	4 75
Coke, furnace, f.o.b. ovens	net ton	3 25 —	3.50
Fluorspar, gravel, f.o.b. mines, New Mexico	net ton	12.00 —	
Fluorspar, standard, domestic washed gravel Kentucky and Illinois mines	net ton	20.00 —	22 00
Ilmenite, 52% TiO_2, per lb. ore	lb	.01½ —	.01¾
Manganese ore, 50% Mn, c.i.f. Atlantic seaport	unit	.25 —	.25½
Manganese ore, chemical (MnO_2)	ne ton	55 00 —	60 00
Molybdenite, 85% MoS_2, per lb. of MoS_2, N. Y.	lb.	.40 —	.42
Monazite, per unit of ThO_2, c.i.f., Atlantic seaport	unit	27 00 —	
Pyrites, Spanish, fines, c.i.f., Atlantic seaport	unit	12 —	12
Pyrites, Spanish, furnace size, c.i.f. Atlantic seaport	unit	.13 —	.13
Pyrites, domestic, fines, f.o.b. mines, Ga.	unit	.11 —	.12
Rutile, 95% TiO_2 per lb. ore	lb.	.12 —	
Tungsten, scheelite, 60% WO_3 and over, per unit of WO_3 (nominal)	unit	2.25 —	2.50
Tungsten, wolframite, 60% WO_3 and over, per unit of WO_3, N. Y. C.	unit	2 50 —	2.75
Uranium ore (carnotite) per lb. of U_3O_8	lb.	1.25 —	1.75
Uranium oxide, 96% per lb. contained U_3O_8	lb.	2 25 —	2.50
Vanadium pentoxide, 99%	lb.	12.00 —	14.00
Vanadium ore, per lb. of V_2O_5 contained	lb.	1.00 —	
Zircon, washed, iron free, f.o.b. Pablo, Florida	lb.	.04½ —	.13½

Non-Ferrous Metals

New York Markets

	Cents per Lb.
Copper, electrolytic	12 75
Aluminum, 98 to 99 per cent	19 00
Antimony, wholesale lots, Chinese and Japanese	4 25
Nickel, ordinary (ingot)	41.00
Nickel, electrolytic	44.00
Nickel, electrolytic, resale	32.00
Monel metal, shot and blocks	35 00
Monel metal, ingots	38.00
Monel metal, sheet bars	40 00
Tin, 5-ton lots, Straits	29 125
Lead, New York, spot	4 75
Lead, E. St. Louis, spot	4.425–4.50
Zinc, spot, New York	5.15
Zinc, spot, E. St. Louis	4.625–4.65

OTHER METALS

Silver (commercial)	oz.	$0.65½
Cadmium	lb.	1.00–1.10
Bismuth (500 lb. lots)	lb	2.00@2.10
Cobalt	lb.	3.00@3.25
Magnesium	lb.	1.15
Platinum	oz.	85.00@ 90 00
Iridium	oz.	160.00@170.00
Palladium	oz.	55.00@ 60.00
Mercury	75 lb.	50.00

FINISHED METAL PRODUCTS

	Warehouse Price Cents per Lb.
Copper sheets, hot rolled	19.25
Copper bottoms	27.75
Copper rods	19.25
High brass wire	16.75
High brass rods	14.25
Low brass wire	18.25
Low brass rods	18.75
Brazed brass tubing	23.00
Brazed bronze tubing	28.00
Seamless copper tubing	20 75
Seamless high brass tubing	18.00

OLD METALS—The following are the dealers' purchasing prices in cents per pound:

	New York Current
Copper, heavy and crucible	10.25@10.50
Copper, heavy and wire	10.00@10.25
Copper, light and bottoms	7.75@ 8.25
Lead, heavy	3.60@ 3.85
Lead, tea	3.00@ 3.25
Brass, heavy	4.50@ 4.75
Brass, light	4.00@ 4.25
No. 1 yellow brass turnings	4.00@ 4.25
Zinc	2.25@ 2.50

Structural Material

The following base prices per 100 lb. are for structural shapes 3 in. by ¼ in. and arger, and plates ¼ in. and heavier, from jobbers' warehouses in the cities named:

	New York*	Chicago
Structural shapes	$2.63	$2.38
Soft steel bars	2.53	2.28
Soft steel bar shapes	2.53	2.28
Soft steel bands	3.13	2.88
Plates, ¼ to 1 in. thick	2.63	2.38

*Add 15c per 100 lb. for trucking to Jersey City and 10c for delivery in New York and Brooklyn.

Industrial

Financial, Construction and Manufacturers' News

Industrial Developments

Rubber.—The Electric Hose & Rubber Co., Wilmington, Del., has added a night shift at its plant, giving employment to about 100 additional men.

The Rubber Production Co., Morgantown, W. Va., has reopened the local plant of the Armorcord Rubber Co., recently acquired under lease. The plant has been closed for about a year past.

The Hood Rubber Co., Watertown, Mass., has adopted a capacity operating schedule in the tire department at its local plant.

The Allen Tire & Rubber Co., Allentown, Pa., has adopted a 20-hour day schedule at its plant at Rittersville, Pa., adding a 10-hour shift, with additional employees, to the former production basis.

Glass.—The Macbeth-Evans Glass Co., Elwood, Ind., is arranging for the early resumption of operations at its local plant, and preparatory to production is rebuilding the No. 1 furnace, adding a new battery of lehrs and making other improvements to cost about $25,000.

The Henryetta Glass Mfg. Co., Henryetta, Okla., has commenced manufacture at 24 shops of its local plant, primarily for the production of lamp chimneys. Other departments will resume at an early date for the manufacture of tableware, lantern globes, etc.

The Interstate Window Glass Co., Kane, Pa., is increasing production at its Wheeling, W. Va., and Lancaster, O., plants.

Ceramic.—Practically all of the sanitary ware potteries at Trenton, N. J., are operating on a full-capacity basis.

The Acme Brick Co., Denton, Tex., has resumed operations at its plant, following a shut-down for several months past. Initial production will be on a basis of about 40,000 bricks per day, with employment of about 100 men.

Leather.—The American Hide & Leather Co., New York, N. Y., has resumed operations at full capacity at a number of its tanneries.

The Deford Tanning Co., Luray, Va., has resumed operations at its local plant, following a shut-down of a number of months.

Iron and Steel.—With the blowing in of the No. 1 blast furnace at the Carrie furnaces of the Homestead Steel Works, Homestead, Pa., March 22, seven of the eight furnaces at the plant are now in operation.

The Carnegie Steel Co. has resumed production at its Farrell (Pa.) works, which have been idle for about a year past. Two blast furnaces will be blown in early in April, and 11 open-hearth furnaces placed in service. Employment will be given to about 1,500 men. The company has blown in another furnace at its Isabella plant, Etna, Pa., and another stack will soon be placed in service at this works.

The American Sheet & Tin Plate Co., Cambridge, O., has started operations at the four remaining mills at its local plant, placing the works on a full operating basis for the first time since last November.

The Wheeling Steel & Iron Co., a subsidiary of the Wheeling Steel Corp., has adopted a 100 per cent operating schedule at its Benwood, O., plant.

The Republic Steel Co., Youngstown, O., is running full in the open-hearth department at its plant, including the entire battery of 14 furnaces.

The Youngstown Sheet & Tube Co., Youngstown, O., has blown in a fifth blast furnace at its local works, making but one idle stack at the plant. This will be placed in service at an early date.

The United States Steel Corp. has placed its Aetna-Standard plant, Aetnaville, O., on a 100 per cent operating basis.

Coke.—The H. C. Frick Coke Co. has fired 200 additional ovens at its Leith plant, near Greensburg, Pa., following a shut-down of more than a year.

Metals.—The Bartlesville Zinc Co., Blackwell, Okla., has resumed production at its smelting plant.

The American Smelting & Refining Co., New York, N.Y., will soon resume operations on a large scale at its smelting plant at El Paso, Tex., for the smelting of lead ores from the mines of the Erupcion Mining Co. and the Ahumada Lead Co., both of Chihuahua, Mexico, with which contracts have been made.

The Michigan Copper & Brass Co., Detroit, Mich., has adopted a 100 per cent operating schedule at its local plant, giving employment to about 800 men. A night shift is being operated until 9 o'clock every evening during the work-week.

Miscellaneous.—The Wilmington Fiber Specialty Co., New Castle, Del., is operating on a full production basis, with incoming orders in excess of capacity.

The Corn Products Co. has commenced operations at its plant at North Kansas City, Mo., recently completed at a cost of about $7,000,000. Employment will be given to 600 persons.

Construction and Operation

Arizona

GLOBE—The Magma Copper Co. has preliminary plans under way for the erection of a new smelting plant and copper mill. A bond issue of $4,000,000 is being arranged, a portion of which will be used for the project.

California

OAKLAND—The California Pottery Co. is perfecting plans for the removal of its local plant to Merced, Cal., where another plant is now being operated by the company. The latter works will be extended to accommodate the equipment from the Oakland plant, and 16 new kilns will be constructed. A complete general line of manufacture will be carried on, including firebrick, face brick, tile, sewer pipe, etc. Frank A. Costello is president.

INGLEWOOD—The Smoot-Holman Co., Los Angeles, comprising a recent reorganization of the American Enameling & Stamping Works of the same city, has acquired a tract of land at Inglewood, totaling about 5 acres, and has preliminary plans under way for the erection of a new plant, to consist of a number of 1-story buildings.

SELMA—The Fresno Tire & Rubber Co., Fresno, Cal., is arranging plans for the immediate erection of its proposed new local plant for the manufacture of tires and other rubber products. It will be 3-story, 60 x 250 ft. John S. Bates, Rowell Bldg., Fresno, is engineer.

COLTON—The Bach Reduction Co., Los Angeles, has acquired property at Colton, and plans for the erection of a new 1-story plant for the manufacture of fertilizer products.

Connecticut

HARTFORD—Fire, March 16, destroyed a portion of the auxiliary plant of the Johns-Pratt Co., manufacturer of compounds, etc., Homestead Ave. and Burton St., with loss estimated at about $15,000. The fire was caused by overheating or short-circuiting in a large enameling oven.

Florida

TAMPA—The Pineapple Products Co., Curry Bldg., recently organized with a capital of $50,000, is planning for the construction of a plant for the manufacture of fertilizer products, in connection with a new local factory for the production of syrups, phosphate, vinegar and kindred specialties. Henry O. Page is president; and William B. Hill, general manager.

Illinois

MT. VERNON—The Mount Vernon Car Mfg. Co. has awarded a contract to the Hughes-Foulkrod Co., Pittsburgh, Pa., for the construction of a 1-story foundry for the production of iron and other metal castings, 132 x 550 ft., estimated to cost about $250,000, including equipment. W. C. Archer is president.

WAUKEGAN—The Board of Works is having plans completed for the construction of a new filtration plant at the city waterworks, estimated to cost about $600,000, including pumping station. Hoad, Decker & Drury, 303 South State St., Ann Arbor, Mich., are consulting engineers.

Kentucky

PAINTSVILLE—The Paintsville Oil & Refining Co. will commence immediately the erection of a new topping plant, with extensive tankage department. A site has been selected near the city. Ralph Stafford heads the company.

Maryland

BALTIMORE—The Liberty Yeast Corp., 4400 O'Donnell St., will build a 1-story addition, 30 x 65 ft., to its ferment department. Equipment will be installed for the production of industrial alcohol. W. A. Boykin, Jr., is manager.

BALTIMORE—The Public Improvement Commission, City Hall, has plans under consideration for the establishment of a plant for the production of alum for the filter beds at the city waterworks, estimated to cost about $12,000. Robert Garrett is chairman.

Massachusetts

MITTENEAGUE—The Strathmore Paper Co. has awarded a contract to the Ernest F. Carlson Co., Springfield, Mass., for the erection of a 4-story addition to its plant, 25 x 200 ft. Work will be commenced at an early date.

SALEM—The Park Leather Co., Mason and Grove Sts., has commenced the enlargement of its plant. Equipment will be installed for increased capacity.

ASSONET—The New England Oil Refining Co., Purchase St., Fall River, Mass., has acquired property at Assonet, to be used as a site for the erection of a new distributing plant.

Michigan

HOLLAND—The De Pree Chemical Co. has awarded a contract to the Frank Dyke Co., Holland, for the erection of a 3-story addition to its plant, estimated to cost about $500,000, including equipment.

CADILLAC—The Cadillac Malleable Iron Co. has broken ground for the erection of a new 1-story foundry, 120 x 200 ft., and annealing building, 90 x 224 ft., for the production of iron and other metal castings. Additional units will be constructed at a later date. The Indiana Bridge Co., Muncie, Ind., has the building contract.

KALAMAZOO—The City Commission, C. L. Miller, city manager, has preliminary plans under way for the erection of a new municipal gas plant, comprising six buildings, estimated to cost in excess of $1,250,000. Burns & McDonnell, 402 Interstate Bldg., Kansas City, Mo., are engineers.

MANISTEE—The Ruggles & Rademaker Co. is making rapid progress in the erection of its new local salt plant, and expects to have a portion of the works ready for service at an early date. The plant has been designed for a capacity of about 8,000 bbl. a day, or approximately 60 carloads, and will give employment to close to 300 men. It is estimated to cost approximately $2,000,000, complete. The company is an outgrowth of the Buckley & Douglas Lumber Co. salt plant, which was destroyed by fire about a year ago.

Missouri

JOPLIN—The Wilhoit Oil Co., Springfield, Mo., E. M. Wilhoit, president, is planning for extensions and improvements in its refinery at Joplin, estimated to cost about $100,000. The present plant will be remodeled.

New Jersey

ELIZABETH—Fire, March 22, destroyed a portion of the plant of the Atlantic Chemical Works, Bayway, near Elizabeth, with loss estimated at about $200,000, including equipment.

TRENTON—The Essential Oil Co., a subsidiary of the American Linseed Co., 297 4th Ave., New York, N. Y., has work under way on the remodeling of the local plant of the American Brass & Lamp Co., recently acquired, and plans to commence production early in June, giving employment to about 50 persons. The plant will be devoted to the manufacture of terpineol (synthetic lilac oil), camphor, terpin-hydrate and other volatile oils. Gustave Mahlck heads the company.

KEASBEY—Fire, March 21, destroyed a portion of the plant of the Carborundum Co., manufacturer of refractory products, saggers, etc., with loss estimated at about $50,000. The plant comprises the former works of the Didier-March Co. Headquarters of the company are at Niagara Falls, New York.

New York

BROOKLYN—Paul Uhlich & Co., 11 Cliff St., New York, N. Y., manufacturers of dry colors, etc., have filed plans for the rebuilding of the portion of their plant on Herkimer Place, Brooklyn, estimated to cost about $20,000.

ONEIDA—The Maxwell Steel Vault Co., 4 Warner St., has completed plans for the erection of the first unit of a new local plant, 1-story, 60 x 90 ft. Work will be commenced in April.

Oklahoma

COLLINSVILLE—The Collinsville Brick Co., has work under way for extensions and improvements in its plant. The capacity will be increased.

MUSKOGEE—The Muskogee Refining Co., South Cherokee St., is planning for extensions and improvements in its local refinery to cost about $200,000, including equipment.

Pennsylvania

PHILADELPHIA — The Continental Leather Co., 311 North 3rd St., recently organized under Delaware laws with a capital of $2,500,000, has acquired the former tanning plants of Janney & Burroughs, Inc., at a receiver's sale. The tanneries are located at Philadelphia, Augusta Springs and Elkton, Va., and will be placed in operation by the new owner at an early date. Perry E. Wurst, vice-president of the Alpena Leather Corp., Alpena, Mich., is president and general manager of the Continental company; Joseph Wayne, Jr., is vice-president and treasurer.

PHILADELPHIA — Montgomery Bros., Inc., 45 South 2nd St., manufacturer of rubber products, has filed plans for the erection of an addition to its plant at Packer and Penrose Sts.

PHILADELPHIA—The Wittman Moriarty Co., 4th and Vine Sts., manufacturer of leather, has taken title to property at B and Westmoreland Sts., 240 x 314 ft., for a consideration of about $30,000, and will commence the immediate erection of a new tanning plant on the site, 1- and 2-story, 77 x 105 ft., estimated to cost about $75,000.

WAYNESBORO—The Frick Co. will build a new foundry at its local agricultural implement plant, to be equipped for an output of about 60 tons of castings per day.

Tennessee

MEMPHIS—Fire, March 18, destroyed a portion of the oil plant of the Royal Refining Co., Hollywood, a suburb of Memphis. An official statement regarding the amount of estimated loss has not been made.

Texas

DALLAS—The Daniels' Chemical Proof Ink & Paper Co., 2212 Live Oak St., is planning for the erection of a new plant for the manufacture of chemical-proof ink products.

HOUSTON—The Humble Oil & Refining Co. is planning for the rebuilding of its tankage plant, destroyed by fire, March 21, with loss estimated at about $500,000

DALLAS—The Trinity Paper Mills Co., 3010 Williams St., has acquired a local site and plans to erect a new plant for the manufacture of waxed papers. J. Y. Webb is president.

Virginia

NORFOLK—The Robertson Chemical Corp., Board of Trade Bldg., is perfecting plans for the rebuilding of its plant in the Money Point section, recently destroyed by fire. It will be 1-story, 75 x 300 ft., and is estimated to cost about $60,000. W. H. Robertson is president.

CHATHAM—The City Council is planning for the installation of a filtration plant at the waterworks. A bond issue of $20,000 is being arranged.

West Virginia

HUNTINGTON—The Liberty Airless Tire Co., Parkersburg, W. Va., C. Lewis Wilson, president, is considering the erection of a new plant for the manufacture of automobile tires at Huntington. Negotiations are said to be under way for a local site.

GRAFTON—The City Council is planning for the installation of a filtration plant at the waterworks. Bonds for $100,000 will be voted.

Capital Increases, Etc.

THE OCEAN LEATHER CO., 40 Beaver St., New York, N. Y., has filed notice of increase in capital from $41,000,000 to $41,750,000.

THE COLAC CHEMICAL CO., Glens Falls, N. Y., has filed notice of increase in capital from $25,000 to $300,000.

THE CONTINUOUS CASTING CORP., Garwood, N. J., has filed an involuntary petition in bankruptcy.

THE MICHIGAN PORCELAIN INSULATOR CO., Hastings, Mich., has filed notice of dissolution under state laws.

WERBELOVSKY BROS., INC., 1160 Flushing Ave., Brooklyn, N. Y., manufacturer of glass products, has filed notice of increase in capital from $200,000 to $300,000.

THE STAR VARNISH WORKS, INC., Hamtramck, Mich., has filed notice of dissolution under state laws.

THE MINER EDGAR CO., Blanchard St., Newark, N. J., manufacturer of chemicals, refined clays, etc., has arranged for a bond issue of $1,000,000.

H. Snowden Marshall and Arthur J. Stevens have been appointed receivers in equity for the ISLAND OIL & TRANSPORT CORP., 55 Liberty St., New York, N. Y.

The General Oil Co., Houston, Tex., has been reorganized as the GENERAL PETROLEUM CO., with a capital of 11,000,000 shares of preferred stock and 1,000,000 shares of common stock, no par value.

THE E. I. DU PONT DE NEMOURS EXPORT CO., 120 Broadway, New York, N. Y., a subsidiary of E. I. du Pont de Nemours & Co., Wilmington, Del., has been dissolved, effective March 31.

New Companies

THE PULP PRODUCTS CO., 405 East Main St., Kalamazoo, Mich., has been incorporated with a capital of $100,000, to manufacture paper pulp and byproducts. The incorporators are Charles E. Taylor, Rossville, Ill.; George C. McCann, Danville, Ill.; and John E. Carey, Otsego, Mich.

THE CORAL CHEMICAL CO., Buffalo, N. Y., has been incorporated with a capital of $60,000, to manufacture chemicals and chemical byproducts. The incorporators are G. D. Fogarty, R. H. Robinson and J. T. Penfield. The company is represented by Stephen V. O'Gorman, Mutual Life Bldg., Buffalo.

THE MEDUSA CEMENT PAINT CO., Augusta, Me., has been incorporated with a capital of 1,000 shares of stock, no par value, to manufacture special cement paints and affiliated products. E. M. Leavitt is president and treasurer; Frank E. Southard, Augusta, represents the company.

THE BLUE GRASS REFINING & PRODUCING CO., Lexington, Ky, has been incorporated with a capital of $50,000, to manufacture refined petroleum products. The incorporators are A. V. Smith, Jr., Walter R. Powell and J. F. Whorton, all of Lexington.

THE SWEDISH CHARCOAL STEEL PRODUCERS, INC., New York, N. Y., has been incorporated with a capital of $50,000, to manufacture steel products. The incorporators are F. Sandelin, W. L. Batt and J. A. Vaughan, New York. The company is represented by F. J. Knorr, Albany, N. Y.

THE CAVE CITY OIL CO., 133 West Washington St., Chicago, Ill., has been incorporated with a capital of $30,000, to manufacture oil products. The incorporators are Edward M. Craig, Irl G. Hipsley and William H. Craig.

THE KONIKOW CHEMICAL LABORATORIES, Boston, Mass., have filed notice of organization to manufacture chemical products. The company is headed by William M. Kent, 52 Chamber St., Boston.

THE ARTCRAFT BRONZE CO., Detroit, Mich., has been incorporated with a capital of $20,000, to manufacture bronze and brass products. The incorporators are George B. Wood, George D. Ostergren and John M. Motschall, 1497 East Grand Boulevard, Detroit.

THE E. L. SMITH OIL CO., Wilmington, Del., has been incorporated under state laws with a capital of $5,000,000, to manufacture petroleum products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

LYNN & CO., INC., Syracuse, N. Y., has been incorporated with a capital of $10,000, to manufacture soaps and kindred products. The incorporators are J. Lindner, H. J. Wilson and A. V. Moliski. The company is represented by Gerber & Winkelstein, Syracuse.

THE HAMILTON OIL CO., Orange, Tex., has been incorporated with a capital of $5,000,000, to manufacture petroleum products. The company will succeed to the business of the Oil Issue Co. W. R. Hamilton is president; H. P. Ingles, first vice-president; and James N. Kincaid, secretary.

THE STATE FERTILIZER CO., Claremont Hotel, Union Stock Yards, Baltimore, Md., has been incorporated with a capital of $50,000, to manufacture fertilizer products. The incorporators are John W. Dasher, Robert S. Collier and J. Bradley Zepp.

THE AMERICAN INDUSTRIAL ALCOHOL CO., Jersey City, N. J., has been incorporated with a capital of $100,000, to manufacture industrial alcohol products and kindred specialties. The incorporators are William K. Faber and Francis Covner, 15 Exchange Pl., Jersey City.

THE FIDELITY RUBBER CO., New York, N. Y., has been incorporated under Delaware laws, with a capital of $250,000, to manufacture rubber products. The incorporators are E. E. and C. R. Allison, New York; and A. K. Dohrmann, Jersey City, N. J. The company is represented by the Capital Trust Co. of Delaware, Dover, Del.

THE HARBOR TANNING CO., Lynn, Mass., has been incorporated with a capital of $10,000, to manufacture leather products. Manuel Ross is president; and Arthur C. Stewart, Medford, Mass., is treasurer.

THE FLAXO CO., Saginaw, Mich., has been incorporated with a capital of $25,000, to manufacture chemicals, chemical compounds and affiliated products. The incorporators are Louis Kuehl, Saginaw; and Philip Catsman, Flint, Mich.

THE PENN-JERSEY FOUNDRY CORP., Camden, N. J., has been incorporated with a capital of $100,000, to manufacture iron, steel and other metal castings. The company is represented by the Corporation Trust Co., 328 Market St., Camden, N. J.

THE KINGSTON OIL CO., Kingston, N. Y., has been incorporated with a capital of $50,000, to manufacture oil products. The incorporators are P. A. Black, J. P. Mack and M. H. Herzog, Kingston. The company is represented by Fowler & Loughran, 293 Wall St., Kingston.

THE UTILITY RUBBER CO., New York, N. Y., has been incorporated under Delaware laws, with capital of $1,000,000, to manufacture automobile tires and other rubber goods. The incorporators are Guy E. Norwood, New York; F. Haskell Smith, Bloomfield, N. J.; and James H. Coghill, Morristown, N. J. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

THE NEWARK COLOR & DYE WORKS, INC., Newark, N. J., has been incorporated with a capital of $100,000, to manufacture chemicals, colors, etc. The incorporators are Irving Rauchberg, Mordecai Segal and Samuel M. Hollander, 790 Broad St., Newark, N. J.

THE GAST-O-PINE CORP., New York, N. Y., has been incorporated with a capital of $50,000, to manufacture chemicals and affiliated products. The incorporators are M. Gast, W. S. Rising and W. C. Cartwright, New York. The company is represented by H. S. Goodspeed, 522 Fifth Ave., New York.

THE GRAND RAPIDS CLAY PRODUCTS CO., Grand Rapids, Mich., has been incorporated with a capital of $25,000, to manufacture brick, hollow tile and other burned clay products. The incorporators are Isaac M. Hamilton, W. E. Brimstin and O. E. Merley, 168 North Michigan Ave., Chicago, Ill.

THE UNITED STATES WAXED & COATED PAPER CO., East Orange, N. J., has been incorporated with a capital of $50,000, to manufacture waxed and other special papers. The incorporators are Colin G. Fink, Walter E. Koerner and Oscar J. V. Aschenbach, 227 Elmwood Ave., East Orange.

THE WEST POINT SHALE BRICK CO., Norristown, Pa., has been incorporated under Delaware laws, with capital of $100,000, to manufacture brick and other burned clay products. The incorporators are George Wagner, Norristown; S. Swigler, Lansdowne, Pa.; and M. M. Sweeney, Philadelphia, Pa. The company is represented by the Capital Trust Co. of Delaware, Dover, Del.

THE LUBRICO OIL REFINING CO., Indianapolis, Ind., has been incorporated with a capital of $50,000, to manufacture refined petroleum products. The incorporators are W. S., R. F., J. T. and Fletcher Johnson, all of Indianapolis.

THE USONA BIO-CHEM LABORATORIES, INC., Wilmington, Del., has been chartered under state laws, to manufacture chemicals and chemical byproducts. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE DUNN-GRENET OIL CO., Pittsburgh, Pa., has been organized under state laws

by P. H. McGuire, W. F. Campbell and V. P. Keefe, Pittsburgh, to manufacture petroleum products. The company is represented by Russell J. Esler, 811 Frick Bldg., Pittsburgh.

THE BLOCHEM LABORATORIES, INC., Brooklyn, N. Y., has been incorporated with a capital of $5,000, to manufacture chemicals, industrial alcohol and kindred products. The incorporators are J. E. Gauthier, A. E. Daub and H. Whyman. The company is represented by David Geiger, 286 5th Ave., New York, N. Y.

THE METROPOLITAN CHEMICAL & NOVELTY Co., Philadelphia, Pa., has been incorporated under Delaware laws, with capital of $500,000, to manufacture chemicals and affiliated products. The company is represented by the Corporation Guarantee & Trust Co., Land Title Bldg., Philadelphia.

THE FIBRO CHEMICAL Co., Boston, Mass., has filed notice of organization to manufacture chemicals and chemical byproducts. The company is headed by E. V. Little, 113 Lincoln St., Boston.

THE GRAYCE OIL Co., Wichita Falls, Tex., has been incorporated with a capital of $150,000, to manufacture petroleum products. The incorporators are W. K. and S. J. Campbell and Carl Pursel, all of Wichita Falls.

THE CENTRAL PERU COPPER Co., New York, N. Y., has been incorporated with a capital of $100,000, under Delaware laws, to operate a copper smelting and refining works. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

THE ANSON BRICK & TILE Co., Lilesville, N. C., has been incorporated with a capital of $30,000, to manufacture brick, tile and other burned clay products. The incorporators are S. H. Clark, B. R. Wall, both of Lilesville; and C. P. Stewart, Pee Dee, N. C.

THE RANDOLPH MICA DEVELOPMENT Co., Birmingham, Ala., has been incorporated under Delaware laws, with capital of $150,000, to operate mica properties and manufacture mica products. The incorporators are Glenn S. Matthews, W. Alfred Gillespie and Andrew C. Roberts, all of Birmingham. The company is represented by the Corporation Service Co., Wilmington, Del.

Manufacturers' Catalogs

THE BINKS SPRAY EQUIPMENT Co., Chicago, Ill., has ready for distribution a short bulletin, No. 4-C, illustrating and describing the Binks spray tower, a water-cooling device suitable for small ice machines, oil engines, water-cooled electrical transformers and other apparatus requiring the cooling of small quantities of circulating water.

THE STEERE ENGINEERING Co., Detroit, Mich., is issuing a sheet on "Use Direct Condensation."

JOSEPH T. RYERSON & SON, Chicago, Ill., has added the magazine feature to its stock list, which will be known as the *Ryerson Journal and Stock List*. The list was formerly published monthly, but will now be published bi-monthly. The January-February issue contains a 30-page magazine section, increased space for new steel products and a section on small tools and machinery.

THE BOWKER INSECTICIDE Co., 49 Chambers St., New York, announces, in a 4-page folder, the establishment of a field service division and of a research chemical division. Dr. M. D. Leonard is director of the field service division and Firman Thompson is director of the research chemical division.

THE DESCHANEL ENGINEERING CORP., New York, N. Y., in an 8-page booklet illustrates and describes Deschanel cableway, hoists and buckets.

THE KAY MFG. Co., Norwalk, Conn., calls attention to its new bulletin entitled "Whitney Free Floating Coupling," which is designed to transmit power from one shaft to another, though the shafts are not in alignment, without causing strains in the shafts or bearings. Disassembled couplings are shown, dimensions are given and also a price list.

THE JEFFREY MFG. Co., Columbus, O., has issued three new catalogs. In Catalog 345, on coal and ashes handling machinery, twelve distinctive type of power house equipments are illustrated and described. Catalog 359 features the Jeffrey single roll crusher. This crusher, which is built in five sizes ranging from 18 x 18 in. to 36 x 54 in. is especially adapted for the power house, to insure a constant supply of stoker or small coal where stock sizes cannot always be obtained direct from mines and only run-of-mine or lump coal is available; or for the coaling station, to reduce run-of-mine and lump coal to proper firing sizes; or for the coal mine to reduce lump coal to small sizes to meet the demand for a uniform stoker coal and to dispose of surplus lump coal. Besides crushing coal the crusher lends itself to the reduction of salt, alum, bone and similar substances. The catalog illustrates and describes the construction and operation of the crusher, including typical installation in service, a table of capacities of the different sizes of machines for use in crushing various grades of bituminous coal, and other information for crusher users. Bulletin 360 features the Jeffrey portable car unloader for unloading coal from hopper-bottom or gondola types of railroad cars. It is designed to enable it to meet various conditions of unloading. It requires a minimum of space and can readily be placed in between the car hopper door and the rails, or, where conditions permit, a more permanent arrangement can be had by placing the unloader underneath the rails and thus eliminate the necessity of resetting it for each car.

THE OLIVER-SHERWOOD Co., San Francisco, Cal., a subsidiary of the Oliver Continuous Filter Co., has issued a new catalog on "Cutless Bearings." Illustrations are given as well as a description of the weak link in every pump, the secret of the cutless bearing, the elimination of expense of machining, the many uses of cutless bearings and a list of pump manufacturers using the bearings.

THE NORTON Co., Worcester, Mass., in a 40-page booklet, illustrates and describes "Alundum Safety Tile," which is for stair treads, floors, ramps, elevator landings, entrances to public buildings or wherever a slip-proof, non-wearing surface is desired. Illustrations and descriptions are given on materials and process of manufacture, its advantages, general characteristic of physical properties, types and sizes and specifications for the proper installation of alundum safety tile. Interesting illustrations are given of the actual use of this tile in buildings, subways, stairs, floors, etc.

THE FULTON FOUNDRY & MACHINE Co., Cleveland, O., describes the Airedale clutch in a bulletin just issued. This clutch is made for services from 6 to 560 hp. in standard sizes, and is applicable for a wide range of machines in many kinds of industries. The clutch will not "grab," but picks up gently and is simple and ruggedly made.

THE MERRILL Co., San Francisco, Cal., announces its new catalog, "Merco Processes and Products." Descriptions are given of the Merco precipitation processes and products and also some of the up-to-date results achieved by representative installations, as well as descriptions of the Crowe vacuum-zinc shavings process, Merrill sluicing clarifying filter, Merco-Nordstrom plug valve, Merrillite and Merco methods for clarifying and precipitating cyanide solutions.

THE PHILADELPHIA DRYING MACHINERY Co., Philadelphia, Pa., has recently issued a 4-page folder which describes the various type of "Hurricane" driers for chemicals, battery plates, pharmaceuticals, electrical porcelain, leather, tobacco, spark plugs, food products, etc. The truck tray drier is described as well as the storage battery plate drier, the tunnel truck driers, automatic conveyor type of drier, cabinet tray drier, continuous sectional conveyor drier and "Hurricane" automatic combination stick and apron tobacco drier.

THE WELLMAN-SEAVER-MORGAN Co., Cleveland, O., has issued Bulletin 71 descriptive of the application of labor-saving machinery, particularly car dumpers, excavators, filling bridges and excavating bridges. It also describes the practical method of working very low-grade ore, especially by the leaching process.

THE COLORADO IRON WORKS Co. has issued Pamphlet 33, on "The Akins Flotation and Aeration Machine."

THE AMERICAN STEAM GAUGE & VALVE MFG. Co., of Boston, Mass., is distributing a folder describing its recording thermometer which has recently made its appearance on the market. This new product is actuated by different methods, depending on the purpose, and either saturated vapor expansion, inert gas or liquid is employed. It is in a 10-in. moisture-proof case to record any temperature up to 1,000 deg. F. at any distance up to 200 ft.

THE UEHLING INSTRUMENT Co., Paterson, N. J., announces two new publications: Bulletin 220, on "Magnitude of the Power Plant's Chimney Loss" and Bulletin 221, on "Relation Between CO_2 and Money Wasted Up the Chimney."

THE NASH ENGINEERING Co., South Norwalk, Conn., calls attention to Bull. 18, on "The Jennings Hytor Vacuum Heating Pump, Steam Turbine Driven," for return line heating systems, drier exhaust in paper mills and other vacuum work where liquid is handled with a gas. The booklet is printed in colors.

THE DORR Co., engineer, of New York, has just published an unusually attractive booklet entitled "Testing That Pays Dividends." It describes the laboratories and testing plant housed in the Westport mill at Westport, Conn., and discloses the philosophy of investigation and research into industrial processes. Individuals or companies confronted with the problem of replacing old processes or developing new ones will find much of interest and profit in the bulletin, a copy of which will be sent on request.

THE WHITLOCK COIL PIPE Co., Hartford, Conn., in Bulletin 30, describes the Whitlock all steel superheater, which represents a comparatively recent addition to the line of heat exchange apparatus manufactured by this company.

THE THWING INSTRUMENT Co., Philadelphia, Pa., in a recent bulletin, No. 10, illustrates and describes Thwing thermo-electric pyrometers, indicating and multiple-recording types.

Coming Meetings and Events

AMERICAN CHEMICAL SOCIETY will hold its spring meeting at Birmingham, Ala., April 4 to 7, 1922.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Baltimore, April 27, 28 and 29, 1922. Headquarters will be at the Emerson Hotel.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Rochester, N. Y., during the week of June 5, 1922. Meetings will be held in the spring instead of in the fall as heretofore.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its summer meeting at Niagara Falls, Canada, June 19 to 22. Headquarters will be at the Clifton Hotel.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its nineteenth annual meeting at Bigwin Inn, Bigwin Island, in the Lake of Bays district, Ontario, Canada, on June 21, 22 and 23.

AMERICAN OIL CHEMISTS' SOCIETY will hold its annual meeting at the Grunewald Hotel, New Orleans, La., May 8 and 9.

AMERICAN SOCIETY FOR STEEL TREATING will hold a sectional meeting at the Bureau of Mines auditorium, Pittsburgh, Pa., on May 25 and 26. The International Steel Exposition and Convention of the society will be held in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-fifth annual meeting June 26 to July 1, at Atlantic City, N. J. Headquarters will be at the Chalfonte-Haddon Hall Hotel.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY will hold a meeting at Lyons, France, June 27 to 30.

IRON AND STEEL INSTITUTE (British) will hold its annual meeting on May 4 and 5 at the House of the Institution of Civil Engineers, Great George St., S. W., 1, London.

NATIONAL ASSOCIATION OF PURCHASING AGENTS EXPOSITION (the "Informashow") will be held in connection with the seventh annual convention of the association at Exposition Park, Rochester, N. Y., May 15 to 22.

NEW JERSEY CHEMICAL SOCIETY will meet at Stetters Restaurant, 842 Broad St., Newark, N. J., the third Monday of April, instead of the second Monday as usual.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY and the AMERICAN PULP AND PAPER ASSOCIATION will hold annual meetings at the Waldorf-Astoria, New York, the week of April 10.

The following meetings are scheduled to be held in Rumford Hall, the Chemists Club, New York: April 21—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting; May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting; June 9—American Chemical Society, regular meeting.

Bad Paint and Good Medicine

THERE was a graduate of the University of Pennsylvania who was engaged in a zinc oxide works where, of a sudden, they had trouble. There was something wrong, something unusual in the product. So the Pennsy man dissolved the product, precipitated the zinc, filtered and then added hydrogen sulphide to the filtrate. This showed a white precipitate. In the back of his head was the recollection that germanium sulphide was white, and he announced his observation of the presence of this rare element. Older heads urged him to calm himself, and assured him that his remarkable find was nothing but sulphur. But he dissolved his so-called "sulphur" in aqua regia and H_2S brought it down again. Other tests confirmed his analysis.

Faithful to his *alma mater*, he sent a sample to the Philadelphia laboratory, whereupon Professor TAGGART called for more, and a barrel of the defective zinc oxide produced a couple of ounces of germanium sulphide. Here was a chance for some interesting work, and at the suggestion of Professor TAGGART an advanced student proceeded at once to a study of the periodic table. Germanium is in the carbon group, titanium and zirconium are respectively above and below it, and its near neighbor in the next, or nitrogen, group is arsenic, with atomic weight of 74.96, that of germanium being 72.5. What followed was suggested by the close relationship between arsenic and germanium in their respective positions in the periodic table, and in the behavior of the germanium dioxide in water, which resembles that of arsenic much more nearly than the oxides of the other elements of its own series. A stable saturated solution contains 0.004684 gram of germanium dioxide per 1 c.c. of water..

Then a test was made on guinea pigs by Dr. JOHN H. MUELLER and Miss MIRIAM S. IZARD to see if a solution of the GeO_2 would increase the red blood corpuscles as does As_2O_3. The results were amazing, and they are reported in the March, 1922, number of the *American Journal of the Medical Sciences*. In all the animals treated the blood count went up over a million per cubic millimeter. With rabbits the same effect was observed. A big old dog weighing 142 lb., with the infirmities of age upon him and a blood count of about 2,000,000 below normal, was tried next. Old Rover got a little above 100 mg. of the aqueous solution injected daily for 9 days, and 234 mg. injected the thirty-second day. He developed a normal blood count on the third day, and 2 months after beginning he was still normal. The excess was eliminated in the urine. The next subject was a man 39 years of age who drank the GeO_2 solution half an hour before meals, and here again was the same effect. Lethal doses of arsenic are about 8 mg. per kilo of body weight, whereas that of germanium are over half a gram. Arsenic is also a cumulative poison, while the cumulative feature of germanium is negligible. It therefore does the work of arsenic, is only slightly toxic, and it looks as though means of overcoming pernicious anemia had been discovered. What organic compounds may be built up on germanium remain to be seen. They are at work over it in the John Harrison laboratory in the University of Pennsylvania and in the Wistar Institute.

Unfortunately we can not give more particulars at present, but the little we have learned goes far to show what a curious series of crosscuts chemistry brings into life. There was a batch of zinc oxide that went wrong. There was a live chemist in the works who knew his own mind well enough to stick to his conclusions until he could prove them one way or another. There was his loyal association with his *alma mater*. And now what follows bids fair to be a great contribution to the healing art.

Doesn't it seem worth while to keep good chemists around?

Containers for Coconut Oil

IT'S CURIOUS how hard it is to be up and doing in the tropics. And yet some of the most energetic men we know live under summer skies all the year around. They are, however, few in number. With most of us perpetual sunshine makes us dozy.

There is the copra business, for instance. According to *Commerce Reports* (Nov. 7, 1921) it is said that despite immense sums invested in coconut plantations, most of the groves of the Pacific are stifled with undergrowth and receive little cultivation.

There are oil mills in the Philippines, Dutch East Indies, Australia, the Straits Settlements and French Oceanica, and these have brought about a better quality of oil by avoiding deterioration of the copra in long transit. But these mills incur serious difficulties in finding good containers. Steel drums are expensive, wooden casks are unsatisfactory, and discarded kerosene cans, which are cheap in some localities, cause trouble in opening them and getting out the oil. Tank steamers present obvious disadvantages in shifting from an outward-bound cargo of petroleum to an inward-bound cargo of edible oil. That is, the disadvantages accrue to the edible oil rather than to the tankers.

This shortage of containers has caused a number of tropical oil mills to give up buying copra save at a fraction of the normal price, and accordingly a great deal of it has been shipped to Europe with the consequent deterioration in transit. It is curious that nobody has invented a cheap container for this valuable oil. Over here nobody seems to think of it, and out there in the tropics thinking is hard work. Maybe the hookworm is the obstacle that lies across the road to invention.

Permanence of Light Aluminum Alloys

DOUBT has been frequently expressed by engineers that light aluminum alloys can come into general use on account of their instability. For instance a British official who is best qualified to state an opinion has been quoted as saying, "Speaking generally, the aircraft industry had experienced great trouble with the alloys." Several instances of rapid corrosion, volume change and season cracking have been quoted, while apparently perfect pieces of duralumin have developed mysterious defects. Nevertheless it is unfair to condemn a metal because certain samples go wrong. Brass jars have been known to crack badly, standing on a shelf. Tin in storage has converted itself into dust. Steel castings have exploded with much fuss. But we have not yet discarded brass hardware, tin plate or steel wheels—the effort is rather to study the causes of the troubles and prevent their reoccurrence. So it is reassuring to read in the Eleventh Alloys Research Report—reviewed at length elsewhere in this issue—that the evidence of 9 years' study "indicates very clearly that the alloys do not deteriorate to any appreciable extent within that period of time, while in regard to retention of shape and dimension they are adequately stable for all purposes except for accurate standards of length."

Experience of years has therefore substantiated the theoretical conclusion that well-made alloys such as duralumin, "A," "E" and "Y" alloy, while they do change at room temperature, and continue to change for years, change in a way which enhances their usefulness rather than the opposite. If this be "instability," give us more of it!

Such alloys rank with steel in their susceptibility to heat-treatment. That is to say, proper heating and cooling will change the strength, hardness and ductility to such an extent as to suggest that an entirely new metal has been generated. They are unlike steel, however, in that changes in physical properties occur at room temperature—some steels will change perceptibly after a short stay in boiling water, but seldom is any change noted at atmospheric temperature. In other words, steel is stable in service; we believe that the strength which it possesses now will be possessed by the same metal after 50 or 500 years, if it is guarded against corrosion, heat or overstrain. Duralumin, "A," "E" and "Y" are unstable when quenched—that is, the physical properties determined a week later will be different than if determined immediately. It is said that they "age."

"Aging" is a rather unfortunate term, for it suggests the general deterioration of faculties as a man grows old. "Maturing" would be more apt, for the changes occurring in light aluminum alloys are similar to those which occur when a boy grows into a man—the boy ages; he also matures.

It is of course important that metallurgists and engineers should know exactly what these changes at room temperature are, in order that they may be able to predict the state of a maturing metal at some time in the future. Recent work on these alloys and on the theory of hardening makes it almost certain that the same kind of reactions go forward in heat-treated steel and in light aluminum alloys.

At the risk of stating well-known things, the analogy will be drawn in detail.

At elevated temperatures the normal constituents of an alloy which hardens mutually dissolve in one another, and distribute their atoms uniformly throughout the mass. With lowered temperature some of the constituents (cementite Fe_3C in steel and Mg_2Si and $CuAl_2$ in the light alloys) become insoluble, precipitate and accumulate into tiny hard crystals. Such reactions take time. If the cooling is quick enough, even the precipitation may be prevented—we fix the solid solution permanently in the cold metal if but a very small atomic movement is possible at the subsequently encountered temperatures. Such drastic chilling gives relatively soft metal—like quenched manganese steel. But anything which allows a little more atomic movement will allow precipitation of the insoluble constituents and their aggregation into minute crystals. Thus, hammering manganese steel hardens it almost instantly; gentle tempering does the same thing to other analyses which are austenitic when quenched.

Atoms comprising quenched aluminum alloys, however, seem to possess enough movement so that the precipitation and accumulation occur in metal at rest and at room temperature—the alloy hardens and strengthens continuously—rapidly for a few days, but continuing at a decreasing rate almost indefinitely.

It seems that maximum strength and hardness in metallic alloys are associated with a uniform dispersion of insoluble hard constituents of a certain size—if too small the metal is soft; as the particles grow the metal hardens; as the particles grow still larger the metal becomes again softer. Maximum hardness (that is to say, "critical dispersion") may therefore be had in two ways—by drastic quenching from the temperature range where all constituents are soluble followed by mild reheating, or quenching at a slower rate. Softer metal in turn can be produced by more prolonged or higher reheating, or by still slower cooling, either of which allows the insoluble particles to coalesce further into a smaller number of larger crystals.

The above statement is a general one, and holds for duralumin as well as for steel. From this viewpoint the maturity of light aluminum alloys at room temperature is no different than tempering quenched steel—maturing is slow and proceeds at a constantly decreasing rate, whereas the effect of tempering is quickly felt. However, we need not feel alarmed to find that duralumin after 7 years has increased in hardness, strength and brittleness, and imagine that the ductility will continually decrease with passing time. At the worst the ductility can decrease only to that value associated with the maximum hardness—further progress of the reaction will soften and toughen the alloy. However, the rate of reaction at room temperature continually approaches the vanishing point, since it is increasingly difficult for growing crystals to attract additional molecules from deeper and deeper regions.

The maximum hardness and strength and the minimum ductility ever to be attained by a matured aluminum alloy should therefore be quickly determined by a series of quenching and tempering experiments—the maximum and minimum of these curves represent the "asymptotic values"; indeed, there seems no reason why the metal could not be put into such shape that further change with time from the hardening reactions would be negligible. In this way we would have light metal like most of our heat-treated steels—metal in metastable equilibrium, but metal which is permanently stable under the conditions of its intended use.

Automatic Processes In Industry

SCARCELY an industry in the country has made more than a start toward the utilization of the principles of mass production by automatic methods which were developed in the great metal-working plants and which have contributed so largely to putting them in their present high place in the world's industrial scale. We have been told that the methods applied to the working of metals cannot be applied so well to other materials and in most cases cannot be applied at all. The truth of the matter is that the particular machines used in metal working cannot often be used. The principle, which consists in the careful analysis of the operations of the non-automatic manufacture of the product and the translation of the results of this analysis into machinery which will duplicate the operations automatically, can be applied to almost any industry. There is a point, however, at which the size or complication of the machinery needed may increase its cost so much as to make its adoption uneconomical. But this is true in only a few cases, and we have no doubt that eventually almost the whole of industry will be on an automatic, mass production basis.

In this connection it was recently our privilege to visit a plant where the automatic side of the glass industry has had a notable extension. For some time the molding of bottles has been an automatic process. Now, in this plant, the drawing of tubing and the manufacture of various articles from tubing have been reduced to an automatic machine process.

This indication of the way the wind blows in ceramics is confirmed by similar beginnings in leather-working, wood-working and other industries. The eventual extension of this tendency will no doubt carry the introduction of automatic processes to the economic limit. But when the possibilities for lowered cost per unit of production and the increased efficiency in the use of men and equipment are considered, it would seem to be the wisest course for industry to automatize as quickly and as widely as possible.

The Waste in Coal Mining

SO FAR as known, no record has been kept of the number of addresses that have been delivered and papers and editorials that have been written on wastes in coal mining, all referring to waste of coal. The waste referred to is of coal that would be valuable only to our descendants many years hence.

No doubt we ought to regard the interest of posterity. Besides leaving coal in the ground, we should do well to employ our present capital and man power so as to leave the maximum of comfort and enjoyment in works of art, public and private buildings, transportation facilities, means of production and fertile soil.

In coal mining we have been wasting some coal, but there has been a vastly greater and more important waste of capital and of man power. The pity of the coal strike that began April 1 is that it will not dispel this economic evil. Everyone knows that there are large stocks of coal on hand and that the strike will not end until the stocks are depleted. Meanwhile man power is lost and capital lies idle.

Coal operators and coal miners use different language, but they say the same thing, that there are too many coal mines, and that means that there are also too many coal miners. The capital invested is not efficiently employed and man power is wasted. Repeatedly the coal miners have employed the strike as a means of passing on the expense of part-time employment to the public, the buyers of coal. In other words, they demand that the public support a partly leisure class, demanding a coal-mining rate that will pay an annual salary for a very limited amount of actual work.

Good use for capital can be found, and when capital is put into one thing that same capital cannot be put into another. If a coal miner works a few hours on each of 150 or 200 days in a year and is idle the remainder of the time, man power is being wasted. A detail in which we may be interested is who pays for the idleness, the public, the coal operator or the coal miner himself, but it is a detail in which posterity will not be interested. Posterity will reflect that we were wasteful of our capital and our man power, although we did a good bit of talking about how we should be careful to leave in the ground all the coal gleanings possible. If that principle were a good one, we might stop building roads and leave the stone for posterity, or stop building steel bridges to leave behind some additional iron ore.

More Pure Than Applied

THE program for the meeting of the International Union of Pure and Applied Chemistry which takes place in Lyons June 28 to July 1 indicates how difficult it is to bring pure and applied chemistry into association when once the habit of separation has been formed. For instance, as reported in the *Journal of Industrial and Engineering Chemistry*, the International Committee on the Elements has agreed to three sub-committees respectively on isotopes, radioactive elements and atomic mass. Three commissions on nomenclature are also to be appointed in reference to organic, inorganic and biological chemistry. An investigation is to be conducted to determine whether the principal chemical periodicals shall or shall not adopt the system of abbreviations used in *Chemical Abstracts*. The program ranges slightly over into the field of applied chemistry in taking up standards in certain phases of the three divisions of this subject—viz., the Bureau of Physicochemical Standards at Brussels, pure products for research in England and the service of Documentation on Industrial and Technological Products at Paris. And applied chemistry is brought into activity in the discussion of international laboratory analysis of food products.

But applied chemistry in its more general sense seems neglected. We had hoped that these more frequent meetings would replace the former international congresses of applied chemistry while maintaining vigorous activity in theoretical work. The two belong together, and each encourages work in the other. The developments coming along in the tanning industry, for instance, are distinctly short-cuts from research in pure chemistry over into its very practical application.

What we miss in this program is something in the way of engineering, technology and industrial chemistry. Of course the scope of these more frequent meetings cannot be as broad as that of the former triennial congresses, but we venture the belief that they would have a livelier interest if provision were made to couple up the subjects discussed with the ways and means that they may be of service to humanity.

Readers' Views and Comments

Atomic Disintegration of Tungsten

To the Editor of Chemical & Metallurgical Engineering

SIR:—The note in your issue of March 22 on "Atomic Disintegration of Tungsten" is of extraordinary interest, and a few comments may be justified.

It is said that the method employed was suggested by astronomical researches at the Mt. Wilson observatory, and I infer that the experimenters have ingeniously obtained, in the laboratory, conditions approximating those resulting from collisions of dark stars or similar bodies in the vacuum of intersteller space. When such collisions take place, there of course occurs a prodigious transformation of kinetic energy into heat of intensity that might easily reach or surpass the filament temperatures calculated by Drs. Wendt and Irion. The solid elementary masses of the colliding bodies thereupon explode like the tungsten filament of the experiment, with incredible violence, the main product always or usually appearing in the spectroscope as hydrogen. This gas, if I remember correctly, was driven off from the nucleus of Nova Perseus at a speed exceeding that of any observed solar protuberance and which remained as our record of the highest velocity obtained by matter until that of the helium alpha particle from radium so far surpassed it. Whatever the results of the work prove to be, all must honor the vision and ingenuity by which cosmic conditions have been so nearly reproduced on a laboratory scale.

The outstanding feature of the report is that tungsten of atomic weight 184 has been transmuted to mercury of atomic weight 200.6. Here is something entirely new; for all the long series of elementary transformations familiar to the student of radioactive phenomena involve a lowering of individual atomic weights. It is not of record that either by natural degradation or from alpha particle bombardment an element has been changed into another of higher atomic weight. A key to the answer may be found in that word "degradation." From the supposed beginning in U or Th, to the ending in Pb or an isotope, each step of radioactive elementary transformation apparently consists of a drop in individual atomic weights, with *liberation* of energy. Admitting this, it is conceivable that from an intensely applied source of supercalescence an atomic system might *absorb* energy, and that, doing so in the work under consideration, some multiple of W (184) may have been energized into some multiple of Hg (200.6); a sufficient amount of H (1) and He (4) being freed to complete the equation.

This would be an "ennobling," in sharp distinction from the "degradation," or loss of potential energy, involved in all previously observed elementary transformations. It would more closely meet the general conception of the term "transmutation" than anything heretofore accomplished.

I may be excused for suggesting that this unique reversal in the direction of atomic weight alteration, however capable of speculative explanation, perhaps casts a shade of doubt on the results that might not otherwise be felt and that all will eagerly wait to see removed. In this connection I venture to mention the possibility of H or He occlusion or inclusions in the metal of the W filament used for the experiment. It is of record that these cause trouble in the "hard" type of thermionic valve radio tubes; the gases being slowly liberated from the W of the filament even after its painstaking purification and under the comparatively mild conditions there existing. Spectroscopic evidence of Hg, also, needs a rigid "third degree" when observed in connection with any form of exhausted-tube apparatus. I apologize to Drs. Wendt and Irion for bringing up these points if, as is probable, they have already been considered.

DALTON M. GOETSCHIUS.

The Standard Chemical Co.,
Canonsburg, Pa.

When Does an Employment Contract Terminate?

To the Editor of Chemical & Metallurgical Engineering

SIR:—I know of no remedy at law for unfortunate engineers or technical men who have, in good faith, signed a valid employment contract before entering such employment. If employment is entered into without such a contract and later the employee is asked to sign a contract which imposes unsatisfactory conditions and is given to understand that his services will be no longer required if he does not sign such a contract, there may or may not be an element of coercion.

In my opinion, the real remedy for such conditions as you have described in your editorial of Feb. 22 lies in the proper education and enlightenment of the engineer or technical man. For years American engineering and scientific schools have prepared their graduates to render not only valuable and efficient service in the everyday duties that they are employed to perform but they have also given them a training which has cultivated the inventive or initiative faculty and foresight to a greater degree than can perhaps be acquired in any other course of human training or experience. Unfortunately engineering and scientific schools have not in the past and still do not, so far as I can learn, attempt to impress upon their students the value of such inventive or creative talents.

On the other hand, these schools have inculcated in the minds of their students a spirit of loyalty to their employers and the strict observance of a code of moral and professional ethics. Without deprecating the inculcation of loyalty to one's employer or the observance of proper moral and professional ethics, it is my opinion that the engineer or technical man who is guided by these high principles in making an employment contract is at a tremendous disadvantage in dealing with the average employer, whether such employer be the sole proprietor of his business or merely an official of a corporation. Unfortunately for the engineer seeking employment, the business-man employer generally has only one motive, and that is to make the best bargain possible. That is the only code of ethics with which he is familiar. He is, however, well aware of the high principles and code of ethics which actuate the average engineering graduate and generally takes advantage of them.

From a legal viewpoint and from the generally

accepted brief code of business ethics which I have above mentioned, the employer is probably within his rights in driving a hard bargain. If the employee does not desire to accept employment under the conditions proposed by the employer, he does not have to, and if, after being employed, the employee is required to accept further unsatisfactory conditions or get out, he is still at liberty to make his choice. Engineers should understand this and also understand that alluring prospects for promotion and for sharing in the profits of his employer are will-o'-the-wisp-like unless written into a contract in plain, unmistakable language that such promotion and sharing of profits are considerations of the contract.

Unless, therefore, the technical man knows the value of his wares and has the courage to demand a fair price for them, he is likely to be the victim of the employer, who, though he may have no knowledge and have no ability to acquire knowledge of technical matters, possesses superior faculties and has had infinitely better training in the knowledge of values and the analysis of character.

If the technical man will stop to consider that many of the large employers of engineers who exact the signing of employment contracts calling for the assignment of all patents or inventions of their employees for no other consideration than that of their wages and employment carry their patents and inventions on their books at an enormous capitalization and use these patents as the means of maintaining a virtual monopoly of their business and, incidentally, of maintaining high prices, such a technical man, from the training he has received, ought to be able to judge the value of his inventions. If he is contributing to the aggregation of patents owned or controlled by such an employer, he should insist upon receiving reasonable compensation for such as he contributes. If he does not insist upon such compensation, he should not later complain that his contract of employment is unjust.

Engineering and scientific schools can do much to alleviate the situation by teaching their students the value of technical service particularly as relates to patents and inventions and teaching them also that the product of their brains is their natural heritage and that they should not sell it for a mere "pot of porridge."

I do not agree with the statement made by W. S. Landis in his discussion of this subject which appeared in your issue of March 15, that "raising of the ethics of the profession would go a long way" toward making unnecessary the form of contract under discussion. The ethics of the profession are already on such a high plane that he who is governed solely by them when negotiating for the sale of his services has an insurmountable handicap.

Nor can I conceive of a just "comprehensive and adequate patent law whereby the granting of a patent assumes novelty, without the burden of adjudicating the same through litigation." It is obvious that if one be deprived of the right to contest the validity of a patent, the Patent Office would have to be infallible, else injustice would be done in some if not many cases. It is humanly impossible to be infallible, and our wise and altogether admirable laws governing the issuance of patents therefore provide for relief where injustice has been or is thought to have been done.

Cleveland, Ohio. FRANK L. SESSIONS.

Philip Argall—A Case of Parallel Invention

To the Editor of Chemical & Metallurgical Engineering

SIR:—The late Philip Argall of Denver, Col., whose untimely passing was noted in your issue of March 29, was a remarkable man. I was well acquainted with him when I held the chair of chemistry at the State University of Colorado, at Boulder; and I am indebted to his fertile and original practical scholarship for many a help. Mr. Argall was far ahead of most of his profession, in mining, milling and metallurgy. It was his bold suggestion that first reduced the resistant Cripple Creek ores, the "tellurides," to subjection in cyaniding. That the tellurides are one of the few cases where gold occurs combined chemically has long been well known. That these tellurides can be easily roasted has also been well known. Thus in the old days of rich specimens, it was common to make show pieces by simply placing the raw ores in a fire, when the tellurium would volatilize off, and the gold would "fry out" in great drops all over the specimen. But it was Argall's brain that saw that the reason raw telluride ores would not cyanide was that the cyanide could attack only free gold; and a simple roasting of the telluride sets the gold free. Mr. Argall put this into practical working at the D. Moffat Works near Florence, Col., back in the '90s. In connection with the recovery of the gold from the cyanide solution, zinc shavings were used to precipitate the metal; but Mr. Argall tried scores of other possibilities.

While he was deep in the midst of that work, I recall that he made me a visit at Boulder, in the course of which we had many a confidential discussion of chemical ways and means. One day he told me, with emphasis of the need of secrecy, that he had succeeded in making common metallic aluminum active, about as active as sodium amalgam, when immersed in water, by the action of such salts as those of mercury or metallic mercury, or both. I listened with no small degree of interest, for that was a new reducer worth attention; but as I did not seem to be as much impressed as he had expected, he paused to hear my reply. I went across the room to the last file of *Berichte*, and showed him the identical discovery, just published in the last number, by Prof. Wislicenus of Leipsig, who had worked out the same invention from the standpoint of organic chemistry. Of course Mr. Argall was almost dumfounded, for he said that I was the first man to whom he had trusted any word of his discovery.

On questioning Mr. Argall and on looking up the date of the receipt of Prof. Wislicenus' manuscript, it appeared that those two men, one in Leipsig, Germany, and the other in Florence, Col., had evidently made the parallel invention within a few days of each other and from entirely different points of attack, one inorganic and the other organic; one from the heart of an old and well-furnished university laboratory and the other in the midst of all the trials and distractions of a workshop. This must have been in the late '90s.

The incident is only one of many showing that new inventions are always in the minds of several men; but it is not often that one has the opportunity to check up the facts in such an incontestable way. The episode shows not only the brilliant working of the inventive mind of Philip Argall but it also throws some interesting light on the close connection between fields of research apparently far apart.

Pittsburgh, Pa. CHARLES SKEELE PALMER.

British Chemical Industries

FROM OUR LONDON CORRESPONDENT

LONDON, March 18, 1922.

CHEMICAL markets are still somewhat uninteresting and although the trend of prices is in a slightly upward direction, this is due more to depletion of stocks than to substantial business. Fertilizers, as mentioned in last month's notes, continue to be an exception, and sulphate of ammonia is almost impossible to obtain for early delivery. Glacial acetic acid is again in demand and a further rise in price is predicted, chiefly owing to failures to make delivery from the continent. The lockout in the engineering trade is not expected to last more than 2 or 3 weeks, but even if a prolonged stoppage is avoided, the effect on the chemical industry will be noticeable, a slight setback nowadays making a relatively deep impression.

SUCCESS OF CHEMICAL EXHIBITS AT BRITISH INDUSTRIES FAIR

It seems unnecessary to deal at length in these columns with the magnificent exhibition organized in London and Birmingham under the auspices of the Department of Overseas Trade. Full reports and comments have appeared in the *Chemical Age* (London) and the *Times Trade Supplement*, while some excellent impressions of the fair appeared in the *Journal of the Society of Chemical Industry* this week. The writer has paid several visits to the fair and the essential point about the chemical exhibits was that perhaps for the first time in this country there was a real attempt at organized as distinct from haphazard presentment. For this credit is undoubtedly due to the Association of British Chemical Manufacturers and instead of a duplication of exhibits, the keynote was specialization and concentration on specific lines not competing too actively with other manufacturers represented at the fair and very often covering some special brand or quality. It would be invidious to refer to any specific exhibits without dealing with all of them, but the fine chemical industry as a whole certainly rose to the occasion, and particularly as regards purity the exhibits reached a very high standard. A particularly British characteristic is the continued existence and progress of relatively small firms, which either alone or as constituent parts of an organization demonstrate that individual effort and initiative upon which the trade of this country was founded have not been entirely eliminated by the war-time tendency of amalgamation. Dyestuffs were well to the fore and a very complete and up-to-date collection of finished manufactures using dyestuffs aroused great interest and compared very favorably with similar exhibits seen by the writer last year at the Chemical Exposition in New York. In fact the method of presentment was perhaps better, even if the range of colors exhibited was not quite so extensive. The size and scope of the fair as a whole may be judged by the fact that in London alone there were somewhat less than 1,000 exhibitors, taking a total space of 200,000 sq.ft., the actual frontage of the stands being over three and a half miles. Even if these notes are concerned chiefly with the chemical exhibits, the remainder of the fair was most illuminating and gave a comprehensive picture of present trade tendencies and of real progress in almost all branches of British manufacturing activity. Exhibitors appear to be well satisfied with the results obtained and are likely to give increased support next year. In addition, there was ample opportunity, apart from the business of securing orders, for exhibitors to become better acquainted by interchange of views on the spot and some interesting developments are expected. Although only about one-twentieth of the whole, the chemical exhibit was generally regarded as the outstanding feature of the fair and its educational value to the public and to the legislature has been appreciable. It will not be out of place to mention that only one of the chemical trade papers really made a feature of giving its fullest support, while the older established journal seems to have failed in its duty as a handmaid to the industry.

FURTHER DECISIONS UNDER SAFEGUARDING ACT

It was decided today that tartaric acid, cream of tartar and citric acid are not fine chemicals and in consequence they will not be subject to duty. Apparently the evidence of foreign manufacturers was accepted in preference to that provided by members of the Association of British Chemical Manufacturers, and speaking broadly, it is thought that in view of the large quantities handled annually, it might even have been possible to classify some of these products as heavy chemicals, although it was not part of the referee's duty to apply any such definition. A further decision was that in the case of lactose, which under the act was subject to duty, whereas Allen & Hanbury, Ltd., claimed that it was really a food, that its manufacture did not call for more skilled chemical supervision than, say, cane sugar and that such supervision was not such as would enable the product to be called a fine chemical. As a result lactose has been struck out of the list of articles subject to duty and general opinion seems to indorse the referee's view.

GENERAL NOTES AND NEWS

The organizers of the proposed Institution of Chemical Engineers have made rapid progress and the drafts of the articles of association and of the bylaws have already been circulated to the advisory committee, which consists of more than one hundred prospective members. The Institution should come into being during the next few weeks. It has been well supported financially and otherwise by the leading members of the profession. It will be noticed that the word British does not enter into the title selected for the Institution and the standard which has been set by those responsible will render it worthy to rank in every way equally with the pioneer American Institute. Some confusion has arisen as to its relationship with the chemical engineering group of the Society of Chemical Industry, but clearly there is no connection, the former being a qualifying and examining institute, while the latter should work in close co-operation and function more particularly as an educational body.

The Plauson colloid mill referred to in my January notes is making further progress, the necessary financial and technical support having been forthcoming, and interesting developments are expected in the near future. It will be remembered that some months ago Plauson, in conjunction with Vielle, took out a very large number of provisional patents and the publication of complete specifications should soon begin.

The Alby United Carbide factories is now definitely being wound up, the negotiations with the Barton group having failed.

The Business Side of Chemical Manufacturing

The First of a Series of Articles Discussing the Non-Technical Departments, Their Shortcomings and the Usefulness of the Technical Man in These Fields—The Organization—The Purchasing Department

By CHARLES WADSWORTH, 3d

CONSIDERABLE attention has recently been focused on the fact that chemists and chemical engineers know so little about the business side of chemical manufacturing. Perhaps it would be more accurate to say the non-technical side of chemical manufacturing, for it includes practically all phases of the manufacturing business which are not strictly technical. For these things there is practically no preparation in technical schools. It is therefore excusable, perhaps, that the technical man should fail to realize the importance of the non-technical at the start of his career. That he should continue to ignore it is unfortunate for the industry and for himself. To drive home to the technical man the vital importance of the field he is neglecting is the main purpose of this discussion. As a corollary it is hoped that employers may be made to realize that technical men possess qualities which are distinct assets in the non-technical side of chemical manufacturing as well as in their special fields.

Relative Importance of Non-Technical Departments

How important is the non-technical side of chemical manufacturing? To arrive at this, let us first consider a theoretical organization. There are eight departments into which the work is usually divided. They may be regarded as the "elements" of organization. They are:

1. Research and development.
2. Operating.
3. Engineering (maintenance and construction).
4. Purchasing.
5. Sales and credit.
6. Advertising.
7. Accounting.
8. Finance.

You must understand that the problem of every organization is different and that the relative emphasis placed on any given department will vary tremendously. A dye plant, for example, will have to have seven research chemists, where a sulphuric acid plant of the same financial size will have none. Again, in a plant which produces large tonnage the chief engineer is likely to be a very much higher priced man than in a plant where the mechanical factors of production are small, and so on. In large organizations subsidiary departments, such as traffic or credit, often become important enough to enjoy separate existence. But every healthy chemical manufacturing plant will have all of those eight departments represented. The aims of each department are under constant scrutiny by the best executives. In fact it may be said that the principal executive effort should be the discovery of fresh ideals and stricter standards for the elements of his organization, in accordance with the principle of balance of which we shall have more to say in a little while.

In the list given above there are three technical departments and five non-technical departments. Is that not food for thought? Five to three! Please let me forestall any argument about the technical department being more important. "What would become of the business if it was not for the discovery of the process and the production of the goods? Where would the business be?" That has a good sound, but the answer to it is, "Just exactly where it would be if you couldn't sell the product, if you did not know accurately whether you had made money or not and if you did not know how to handle money! Nowhere!" Talk to executives about the situation. Consider why it is that in the long run the purchasing agent, the sales manager and the auditor get as much salary as the head of research, the operating superintendent and the chief engineer—sometimes more. What is the answer? That only three-eighths of the business of manufacturing chemicals is technical. Indeed in arriving at this figure we have assumed that all the work of the technical departments is technical, which is far from the case. But we are interested only in bringing forward the fact, novel and a little bitter for the technical man, that non-technical work is more important to the organization than technical work.

Strength and Weakness in an Organization

Before we undertake a detailed study of any of the individual departments, it will be worth while for us to consider the organization as a whole and to bring to light any generalizations as to causes of strength and weakness. It will give us a better perspective through which to gage each element of the organization. Organization is a human machine and its problems are the problems of the human equation. Retaining our analogy to a machine, we can say that an organization to run smoothly must be well balanced and that its parts must be in good condition. Lack of balance indicates weakness, just as balance indicates health. In studying a particular organization to determine its specific weaknesses (for every organization will have weaknesses—it is inevitable, since its elements are human beings) the best way to proceed is to study routine. With a knowledge of normal routine it is comparatively easy to locate departures from it. Sometimes these departures indicate executive wisdom but more often a lack of understanding of the functions of a given department.

The best way to understand this is to study specific cases. If we follow a purchase requisition through from its origin until the purchase order is ready to mail, we shall discover who the big men are and what departments are not functioning properly. We may

find that some one who is not the purchasing officer carries out the negotiations. A requisition for a specific piece of apparatus is turned in to the purchasing agent, who then transcribes it on the purchase order form. This means that the purchasing agent is nothing more than a clerk and that his department contains only a small part of the invaluable data which it should contain.

Again, how are the data of the accounting department obtained? Are the forms designed for its convenience or does it have to glean information from operating department forms? Are its reports turned in on time or is there delay in making them out? In obtaining answers to these questions we shall be able to determine whether the accounting department is being treated with proper respect or whether the factory men regard it as a nuisance and adopt a condescending attitude toward it. Still again, a decision to shut down a unit in the plant is made. Who makes it? Who is consulted? Does the superintendent say "please" and "sir" to the chief engineer or does he forget to warn him that less power and steam will be needed? All of these things are indicators. They show us very conclusively whether there is a lack of balance in the organization and where a corrective is needed.

Weaknesses of the Executive

There is another type of weakness in organizations not due to the departments but to the executive. This weakness—the weak executive—may take a number of forms, but there are three which are especially common and therefore deserve mention. The first has already been mentioned. It has to do with lack of familiarity with non-technical departments on the part of technical men. Unfortunately, the technical man who becomes an executive is not an exception to the rule. He is made an executive largely because he is familiar with company procedure or because he is the logical man to promote. After his elevation he becomes absorbed in the routine of his position and does not feel called upon to round out his experience in other fields. The technical man who is head of his own business is, on the other hand, even more apt to become wedded to bad practice in his non-technical departments.

The second type of weakness in executives consists in a belief in the dignity of executive office. This manifests itself in a reserve toward subordinates which kills any possibility of intimacy and therefore closes the most perfect contact which the executive has with his organization. Without it he has no way of discovering what is happening, what dissensions are brewing, what ill feeling exists. Weaknesses that appear in his organization are often a matter of distinct surprise to him.

Lack of Consistent Policy

Finally, the third weakness consists in a lack of consistent policy. Vacillation is perhaps the most disrupting thing that any organization can have. It may be the fault of the board of directors or it may be the fault of the executive. Perhaps it may be that a department is created and then given up. Perhaps men are taken on for a special purpose and in a few months are discharged arbitrarily. Perhaps the change may be only the rerouting of an office form and then a switch back to its former route. Whatever it is, little or important, it affects the morale of an organization. Only those who have experienced such things can realize how serious it is. Vacillation must in no way be confused with the progressive changes which a good executive introduces. An organization is very quick to recognize the difference between progress and vacillation. Too often expediency is the evil genius of the executive.

All of these things tend to create a lack of balance in the organization and balance is the name we have given to the principle which keeps the organization in smooth equilibrium. Your organization may consist of one man who is simultaneously the head of every department or it may be so large that hundreds of men are necessary to accomplish the routine. This principle of balance is just as inescapable for the one as for the other.

The title of this article is the Business Side of Chemical Manufacturing, so let us get back to the subject. Perhaps we are in a better position to discuss the details of the various departments by reason of our digression. We shall try to develop the aims of a normal department and discuss the methods by which the work is accomplished. We shall try to show that technical training is of great assistance when it is given the opportunity. Perhaps we shall be able to indicate definite ways in which technical men may become familiar with the work of non-technical departments. (By this I do not refer to business courses, but I want to take this occasion to indorse such courses when given by reputable organizations. A technical man can go very far without finding a better paying proposition than a reading course in Modern Business Methods or a night school course of the same kind. That is personal experience.) Finally, there may be an occasional idea advanced in the line of enlarging the scope of existing departments to include functions which have been discarded.

Perhaps it has already occurred to some of you that the word technical training was a happily vague phrase which covered a multitude of sins. It is. There are many sins, too. I have encountered technical training which was not worth as much as a good grammar school education; but, vague though it is, the phrase has certain connotations and means, if nothing else, familiarity with scientific vocabulary and method of work.

The Purchasing Department

The purchasing department buys raw materials and equipment for the business. In order to do this, it is necessary for the department to know:

(1) Specifications—what to buy!
(2) Consumption—how much to buy!
(3) Markets—when to buy!
(4) Transportation—where to buy!

This seems rather elementary, and yet it is in those four words that we can condemn the average purchasing department today. A purchasing agent is very likely to know the market for raw materials which are used in his plant and he is apt to know something about transportation. But if he knows anything about specifications or consumption, it is so much parrot talk and he doesn't *know* it. He is usually woefully weak on new equipment, for he does not understand it, and is unintelligent on the general stock of material which is kept on hand. Let us consider some of the things which lie behind the four words given above.

It will be easier to study by the case method and so

we will watch a well-organized purchasing department act in the purchase of a piece of equipment and then in obtaining a supply of raw material.

Equipment

A manufacturing department sends in a requisition to the superintendent's office for a kettle. It is sent on with his O.K. to the purchasing department. It is perfectly safe to assume that the details given about the kettle are insufficient to complete the purchase, so the first thing that must be undertaken is the completion of the requisition by conference with all of the interested parties. This may include the engineering department, and a blueprint of the kettle may be forthcoming. It is even possible that this was turned in with the requisition. In any case the purchasing agent first puts himself in possession of all the data that are available and he then knows the material preferred, the probable corrosion, the pressure under which it will be operated, whether there is to be a jacket or a coil, and the dimensions and details thereof. In addition he knows the kind of stirrer desired, number of revolutions per minute, kind of driving mechanism, outlets and inlets to the jacket and kettle and so on. It can honestly be said that the efficiency of the purchasing department in making this purchase will depend upon the thoroughness with which the details of this equipment are mastered. I do not mean memorized, but understood; so that the purchasing agent can of himself make or authorize changes in the specifications.

Consulting the Card Index

And in the meantime the purchasing agent has been consulting a file of cards, labeled "Equipment." On the card labeled "Kettles" there is listed all those firms which are in a position to supply equipment of this type. An appropriate mark identifies each firm as having estimated previously on similar work or as having supplied equipment before. The most promising firms are looked up in an additional catalog of firms alphabetically indexed. These cards contain a history of the purchases made from a given firm with comments as to whether the transaction was satisfactory and whether the equipment was reliable. If the kettle is a replacement, another index is consulted called the plant ledger which gives a history of that particular piece of equipment on one of its cards. A similar history of every important piece of apparatus in the plant is contained in this index. Finally, a file of manufacturers' catalogs is searched for additional information. This completes the investigation in the organization.

Sending Out Inquiries for Bids

The purchasing agent is then ready to send out inquiries. The method of canvassing the market for material is thoroughly well known and yet withal very poorly done. Ask anyone who has to quote on material or equipment how easy it is to understand the average letter of inquiry except where no confusion is possible. As the bids come in, it is sometimes a really difficult thing to determine whether everyone is bidding on the same equipment. A separate file is often kept on which the data obtained from answers to the bids are summarized. Finally, after the purchase order is made out and sent, a copy is retained in the purchasing office on which to keep a record of the follow-up work which is done. This follow-up consists in ascertaining whether the time of delivery on the original contract is to be adhered to and perhaps in following the freight shipment after it has left the supplier.

A word at this point on purchase order forms is not out of place. Too often these forms are miserably designed. Study those that come in from the outside some time and construct a form which will be satisfactory, complete and clear. The best forms often belong to dealers or traders who are not producers. Purchasing is even more vital to them than to manufacturers, for it takes the place of their production department as well as occupying its own important functions. Some large corporations are cursed with the most inefficient, vague forms that exist. It is a minor point, but one which reflects the finesse and technique which has been put on the purchasing effort.

Can you see in the purchase of that kettle where a technically trained man would have an advantage? How much easier it would be for him to understand specifications and to make sure they were complete? How much easier it would be for him to decide whether the differences between two pieces of apparatus estimated by competing firms were serious or minute?

Raw Materials

Now let us follow the same department in the purchase of a quantity of raw material for the plant. As in the case of the kettle, the requisition may originate in one of the departments, but more likely it originates in the purchasing office itself. A file of stock cards, one card for each material, shows purchases, receipts and consumption daily. It may also contain such other information as the origin of the material, chemical analysis, usefulness, etc. When the stock of material as shown by the cards reaches a certain definite minimum, which may be a month's supply or only a week's supply, the purchasing agent puts through an order for more material. He may get it from a single source or he may shop for it (that is the name given to the method of purchase followed in buying the kettle). Quite frequently raw materials are contracted for on a yearly basis, though seldom in the last 2 years for many obvious and grim reasons. On the other hand, even in normal times with steady consumption, the purchasing agent often prefers to take a chance on the spot market, which means immediate purchase. Otherwise, the system is the same as already outlined in the case of the kettle.

Pitfalls for the Purchasing Agent

Oftentimes this kind of purchasing is very intricate. The specifications for chemicals may be negligible. They may be standard throughout the trade. They may, on the other hand, be very special, based perhaps on a definite percentage composition. Indeed the method of analysis is often of necessity the crux of the whole purchase. Again, do you see that technical training would have value? Consider this. Can your purchasing agent decide of himself that the analysis giving 93 per cent material had been properly carried out? Can he talk to the referee about the technique of the method? If he can't, consider my friend, Smith we'll call him, who lost $10,000 on one purchase through just such an error. He did not know exactly what the per cent analysis meant, although he thought he did.

Another memory! Purchasing Agent Jones made a very advantageous buy of a heavy chemical on the

spot market. The material began to come into the plant and the available storage space at the point of consumption was soon used up. Other storage space about a half mile from the consumption point had to be utilized. When the raw material stored at a distance was being consumed, the increased cost of handling boosted the cost of raw material well above the price of that material then on the spot market. The advantageous buy turned out to be a very poor buy.

Still again, on a contract for a large number of cars of raw material each month shipment was usually made all at once. These cars arrived about the same time and in order to avoid demurrage to the railroad they had to be unloaded immediately. If they had arrived even approximately at a given rate they could have been unloaded so that the material would be consumed straight from the cars. This would have avoided a rehandling charge and saved several cents per hundred pounds.

The Tragedy of Inefficient Purchasing

Such errors are unfortunately very common. They are typical of a large number of mistakes in purchasing which have come to my personal attention. You will realize that very many of these would pass unnoticed in an organization. That is the tragic part of inefficient purchasing, that no one realizes that it is inefficient. Neither of these two problems has ever been completely solved, but that only adds zest to the game.

The purchasing agent must also know a good deal about transportation. This includes not only a knowledge of routes so as to obtain best deliveries for materials in transit, but ability to follow up shipments on the way to the plant, to trace lost cars and understand the recovery of damages from the railroad for losses in transit. Sometimes when the company is large enough there will be a separate traffic department, but that will not relieve the purchasing agent of knowing some transportation.

Interviewing Salesmen

Not infrequently purchasing agents will regard salesmen as a cross between a nuisance and a performing dog. He will instruct them to call between 1 and 1:30 on Mondays, Wednesdays and Fridays or some such arbitrary time. When he does see them he makes the salesmen perform under difficulties. A brusque, testy air which keeps salesmen hurried and ill at ease! It was very aptly described by a good friend of mine as the "horse-trading attitude." The result is that oftentimes the purchasing agent loses an important message. Salesmen are his antennæ, his contact with industry and progress. It has always seemed to me that here was the purchasing agent's main job: to know salesmen, to make friends with them, to know their products. The stories are too numerous to count of the salesman who has delighted in slipping one over on the rough horse-trading purchasing agent. Courtesy pays in more ways than one. When a purchasing agent knows more about the product than the salesman does, then he may be justified in being brusque. How many purchasing agents are there who can do this? Practically zero. And yet I have seen salesmen dismissed curtly by a purchasing agent who could not have mentioned a single use for the product, without even attempting to discuss the comparative merits of its competitors.

In addition to salesmen, purchasing agents have a few other antennæ out in the world. One of the most useful is the advertisements in the technical magazines. These and the excellent Chemical Exposition at New York will keep him remarkably well informed. If a technical man wanted to be better informed than almost any purchasing agent, at least in the matter of equipment, he would need to do little more than keep up on advertising in the technical papers. It sounds simple, doesn't it? You would almost imagine that a great many technical men would take advantage of this very simple procedure, but they do not. Ninety per cent of the technical men whom I know cannot take a single piece of equipment and give a decent résumé of the different types on the market, mentioning the relative advantages and disadvantages of each. Ninety per cent is not estimate, it is count. How about you? How many pieces of equipment do you know? As a technical man you cannot be sure that your process is running at its maximum efficiency if you do not know equipment. The same thing is also true if you do not know the raw material market.

And yet, with all their ignorance, technical men have understanding which would be of great service, if properly developed, in a purchasing department. Of course, if your company has only a clerk who is called purchasing agent, while the actual work of negotiation is carried out by the superintendent or the chief engineer; a purchasing agent who merely transcribes requisitions onto purchase orders, then they will not need, nor will they understand the need of a technical man in the purchasing department. But they are losing the invaluable asset of centralized control of purchasing with all the vast store of knowledge which would accrue from it.

Technical Brains Needed in the Purchasing Department

Any well-organized purchasing department needs technical brains. I do not mean that a technical man is fitted, *a rerum natura*, to take charge of a purchasing office. Not without an adequate preparation in the technique of purchasing which is intricate, difficult and vital. But I suggest this prescription to any technical man who is doing a technical job and who is perhaps a little discouraged at the prospects. Ask the boss if you can't do some purchasing. Take a job as clerk in the purchasing office. Never mind the salary! Ask if you can't meet the salesmen. Start some of the card indexes mentioned in these paragraphs. Collect all of the catalogs you can and know the products. Read the advertisements in the technical magazines. If the purchasing agent is a good one, you will be his right-hand man inside of 2 years. If not, you will either have his job or be qualified for a job with a corporation where a good purchasing agent is appreciated. It will be interesting. Try it.

Perhaps you are an employer and have a purchasing department. Has it all the functions it should have? It hasn't? But you can't put any more responsibility on the present incumbent? Well, try a young technically trained man! Lord knows they are cheap enough. Give him a conception of the way to handle a purchasing department and then turn him loose. I will gamble the result will not be disappointing.

Finally, as a technical man, you should realize that purchasing is a vital function of your business and that you must understand it.

Chicago, Ill.

Contributions to the Study of Ammonia Catalysts—V

The Concluding Article of This Series, Which Takes Up in Detail the Effect of Pressure on Catalytic Activity as Determined by the Fixed Nitrogen Research Laboratory*

By ALFRED T. LARSON

IN MAKING a preliminary study of an ammonia catalyst, one is first concerned with the activity of that material at different temperatures and pressures. If the activity is reasonably high, it then becomes important to consider such factors as longevity and recovery from contact with poisons. But activity tests must come first. In order to examine a large number of catalyst materials, activity tests ought to be easily and inexpensively made. Now, testing at low pressures, particularly 1 atmosphere, is relatively simple and rapid. This method would therefore provide the most convenient way in which to study the activity of ammonia catalysts, provided, of course, that the behavior of such catalysts at high pressures could be predicted from results at low pressures. If this were feasible, it would then be possible to avoid the more laborious and expensive high-pressure testing.

In the preceding paper of this series, it was intimated that the decrease in efficiency of ammonia catalysts as the pressure is increased is much greater for some catalysts than for others. That is, if the tests at low pressure, say 1 atmosphere, show the catalyst to be very active, it may not be safe to assume that this catalyst will be equally efficient at higher pressures. It will be the purpose of this paper to present the experimental results which have been obtained in testing a variety of catalysts, and to show to what extent results of tests at low pressures are useful in predicting their behavior at higher pressures.

Apparatus and Procedure

In earlier papers we have called attention to some of the difficulties which must be faced if exact information concerning the behavior of ammonia catalysts is to be obtained. The need for known regulation of temperature, pressure and purity of gas cannot be too strongly emphasized. Unless all the factors which influence the behavior of a catalyst are under proper control, one cannot hope to obtain comparable results. Therefore, in studying the effect of pressure on a variety of ammonia catalysts, we have attempted, in so far as our present technique would allow, to establish complete identity of conditions. By carrying out all the tests on the various catalysts within bombs of the same type, all of which have been found to be strictly comparable; by employing the same instruments and regulating devices in all tests; by operating on the same purified gas and by reducing all catalysts under the same conditions of temperature and pressure, it is believed that identity of conditions has been obtained.

The apparatus employed in this investigation was described in article II of this series.[1] The arrangement of the apparatus was given in Fig. 1, while the details of the catalyst bomb were given in Fig. 4. This equipment was specially designed to give complete identity of conditions and to be capable of operation at any pressure up to 100 atmospheres. The four bombs employed in these tests were found to give the same results when operating on the same catalyst under the same conditions of temperature and pressure.

The catalysts, all of which were iron oxides with different kinds of promoters, were reduced in a 3:1 mixture of hydrogen and nitrogen at 1 atmosphere pressure and the following temperatures: 24 hours at 300 deg. C., 24 hours at 350 deg. C. and 24 hours at 400 deg. C. At the end of the third day the temperature was raised to 450 deg. C. and the ammonia samples taken at regular intervals until the conversion became constant. All catalysts were tested at a temperature of 450 deg. C. and at pressures varying from 1 atmosphere up to 100 atmospheres. Each catalyst was tested on pure, dry gas, and on pure gas humidified at 25 deg. C. and 100 atmospheres pressure. This gave a gas containing 0.031 per cent of water. The purification of the gas and the method of its humidification were described in article II of this series.

Summary of Results

In Table I we have summarized the results of tests on eleven catalysts, the pressures being 1, 10, 31.6 (450 lb. gage pressure) and 100 atmospheres.[2] The table includes the performance of each catalyst on both dry and wet gas. In each case we have given the actual

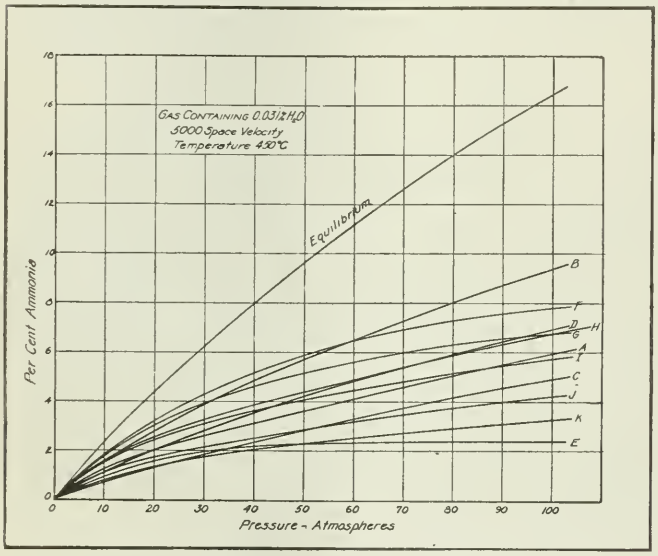

FIG. 2—EFFECT OF PRESSURE ON PER CENT OF AMMONIA USING POISONED GAS

percentage of ammonia produced (per cent NH_3) and also the efficiency (per cent Eff.) that is, the ratio of the actual percentage of ammonia in the gas to that theoretically possible under the conditions in question. Since all these catalysts would be very nearly 100 per cent efficient at 500 deg. C., a lower temperature—namely, 450 deg. C.—was selected, where the real differences in activity are more apparent. The space velocity was 5,000—that is, 5,000 liters of gas were passing over the catalyst per liter of catalyst per hour.

In representing graphically the results of Table I, we have plotted the change in the percentage of ammonia as the pressure is changed and also the variation in efficiency as the pressure is changed. The latter method of expression is the more convenient basis on which to consider the behavior of a catalyst at different pressures, so we shall limit our discussion to Figs. 3 and 4.

In Fig. 3 it will be noted that all the catalysts at 1 atmosphere pressure have an efficiency in excess of 80 per cent. At 100 atmospheres only four are able to maintain that high value. It will also be noted that at 1 atmosphere the catalysts *B*, *C* and *D* show the lowest efficiencies of the group, yet at 100 atmospheres they, together with catalyst *A*, are the only ones which maintain an efficiency of 80 per cent or better. It is evident therefore that one cannot predict from the results on dry gas at 1 atmosphere what the efficiency will be at higher pressures.

Relation of Efficiencies at Different Pressures

All the results which we have accumulated indicate that a catalyst does not increase in activity as the pres-

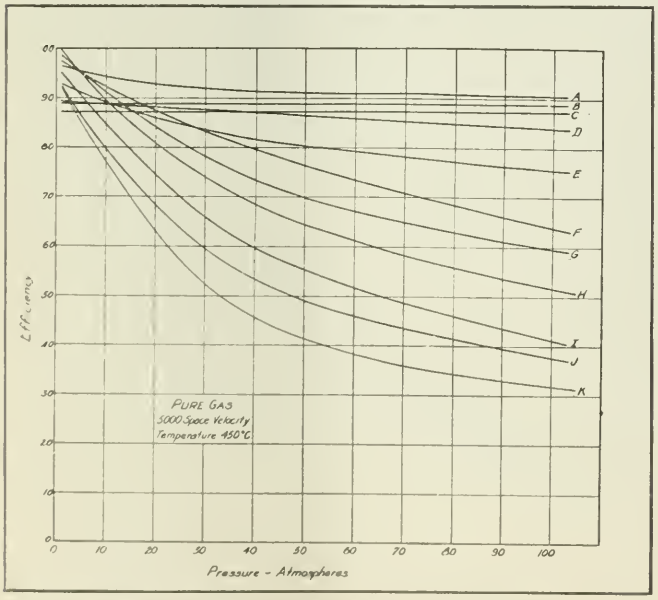

FIG. 3—EFFECT OF PRESSURE ON EFFICIENCY OF CONVERSION USING PURE GAS

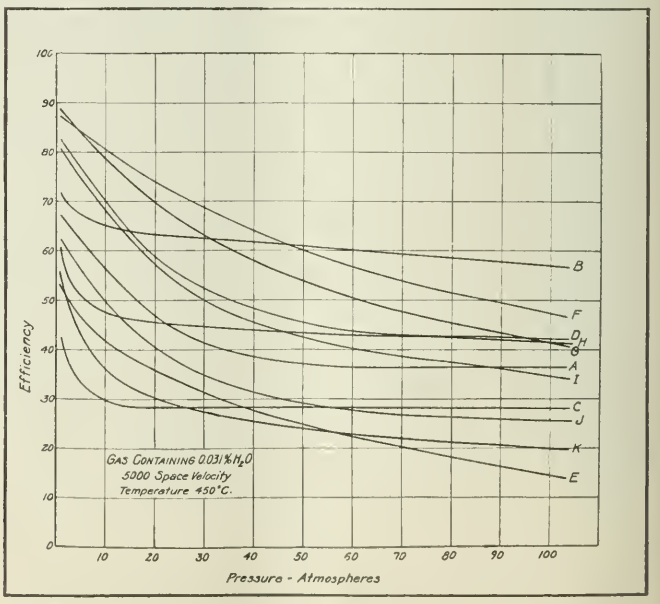

FIG. 4—EFFECT OF PRESSURE ON EFFICIENCY OF CONVERSION USING POISONED GAS

sure is increased. This was probably to be expected and needed only experimental confirmation. It is not, however, so easy to understand why a catalyst like *C*, for example, which is only about 87 per cent efficient at 1-atmosphere, should retain practically that same efficiency at pressures up to 100 atmospheres. We might expect that at 1 atmosphere it would be more efficient than those catalysts which show such a rapid loss in efficiency with increase in pressure. In presenting experiments dealing with the mechanism of the synthetic ammonia reaction, we hope at a later date to discuss more fully these peculiarities. For our present purpose it is sufficient to recognize that efficiency tests at a low pressure are not a safe basis for predicting the behavior of catalysts at a higher pressure.

If, however, the efficiencies at two pressures are known, say at 10 and 30 atmospheres, or better still at 30 and 50 atmospheres, from the general trend of these efficiency curves a very close estimate can be made of the efficiency at some higher pressure, as for example 100 atmospheres. A very large number of our catalysts have been examined in this way and the results have in general been found to be trustworthy.

Effects of Catalyst Poisons

When a catalyst is tested with a gas containing a contact poison, as for example water vapor, we find the same characteristic behavior as has been noted above. Fig. 4 shows the change in efficiency with change in pressure when operating on a gas containing 0.031 per cent water. As would be expected, all the efficiencies have dropped, although in changing from dry to wet gas the order has been somewhat altered. Thus, catalysts which show the highest efficiency on dry gas no longer rank first when tested against wet gas. These results indicate very clearly the importance of making tests with a gaseous mixture of known composition. If the character of the gas is not kept the same in all the tests, the results obtained will not be comparable.

The results in Fig. 4 also emphasize the importance of knowing the behavior of catalysts on impure gas. In technical operation it might not be feasible to produce a gas of such purity as that employed in these "pure gas" tests. Certainly, to make a selection of a catalyst for technical operation from such pure gas tests would not be safe. On wet gas, catalyst *B*, for example, is very much better than catalyst *A* which gave the highest results on pure gas. Of course, it is true that the discrepancy between *B* and *A* would become less as the temperature is raised, but still the optimum temperature when operating on wet gas would certainly be lower in the case of catalyst *B*.

Perpetual Inventory of Stores Discussed in Chamber of Commerce Pamphlet

The Fabricated Production Department of the Chamber of Commerce of the United States has just issued an important pamphlet on perpetual inventory of stores control system as an aid to manufacturing plants. The pamphlet discusses the advantages which accrue from the use of the perpetual inventory. They include a control of the investment in stores to an efficient minimum, the elimination of duplication in types of supplies and the automatic ordering of supplies which need replenishing. This question is timely and will receive much fuller treatment in these pages shortly.

Resale Price-Fixing Scheme Declared Unfair by Supreme Court

By Wellington Gustin
Of the Chicago Bar

UNFAIR competition in trade and commerce is the special concern of the Federal Trade Commission. Its acts and rulings are reviewable by the United States Supreme Court. Unfair dealing in industry is not defined in the act, and decisions of the commission and federal courts are left to determine what constitutes this offense. So a decision of the Supreme Court upholding or reversing a decree of the Trade Commission is of momentous importance to commerce and industry.

The Colgate & Co. case and the Schrader's Son, Inc., case have become historic in industry, and now comes a decision of the U. S. Supreme Court in the case of the Federal Trade Commission vs. Beech-Nut Packing Co. The decision is arrived at through a divided court, five judges to four.

How the resale price of a product may be controlled and forced to be kept up to a specified or determined figure has been the concern of many manufacturers and distributors of various kinds in practically every field of industry. Few have been able to devise a scheme or plan that will stand a test in courts. And one that has been tested out and found to be not in conflict with the Sherman anti-trust law, the Clayton act and the scrutinizing eye of the Federal Trade Commission must be accorded as being ingenious indeed.

Therefore the Supreme Court's recent decision in the Beech-Nut case is of special moment. The Federal Trade Commission had condemned the plan of resale of the Beech-Nut Co. on its products being sold throughout the United States and ordered the company to desist from the alleged illegal practices.

Charges Against the Company

It was charged that the company had adopted and enforced a system of fixing and maintaining certain specified standard prices at which its products shall be resold by purchasers thereof, including jobbers, wholesalers and retailers, with the purpose and effect of securing the trade of such distributors and of enlisting their active support and co-operation in enlarging the sale of its goods, to the prejudice of its competitors who do not require and enforce the maintenance of resale prices for their products; and with the purpose and effect of eliminating competition in prices among all jobbers, wholesalers and retailers, respectively, engaged in handling the company's products, thereby depriving such distributors of their right to sell, and preventing them from selling its products at such prices as they may deem to be, and as are, adequate and warranted by their respective selling cost and efficiency, and with various other effects; and that the company as a means of making effective its system of resale prices and of inducing and compelling its customers and the dealer customers of its customers to maintain such resale prices has:

Made it known generally to jobbers, wholesalers and retailers, respectively, that it required and insisted that they should sell its products at the resale prices so fixed by it, and refused to sell to jobbers, wholesalers or retailers not maintaining such prices; that the company threatened and refused to sell to all jobbers, wholesalers and retailers who failed to maintain the

resale prices so fixed by it, or who sold to other distributors who so failed; that the company caused the diversion of retailers' orders away from jobbers and wholesalers who did not maintain the resale prices so fixed by it, and refused to supply other jobbers, wholesalers and retailers failing to maintain such prices; that the company solicited and secured the co-operation of wholesalers, jobbers and retailers in reporting price cutters, all in pursuance of its efforts to ascertain the names of all distributors of its products who had failed to maintain the resale prices or who had sold to other jobbers and others failing to maintain the fixed prices; that it entered in card records kept by it the names of all dealers reported to it, either in this or other ways, as not maintaining its resale prices or as selling to those who in turn did not maintain such prices, and had taken various measures to prevent all such dealers from obtaining further shipments of its products from any source until it had received from them declarations, promises, assurances, statements or other similar expressions to the effect that in the future such dealers intend to and will sell such products at the resale prices fixed by the company and will refrain from selling to others who fail to maintain such prices; that the company employed various other means and methods for the enforcement of its system of maintaining resale prices.

Charges Found True by Commission

The commission found that the charges were substantially true; that the company selected its wholesale and retail dealers as desirable customers because they are believed to be of good credit standing, willing to resell at the fixed prices and maintain same. Such are designated by the company as "selected" or "desirable" dealers, and include the greater number of such dealers throughout the United States.

The Beech-Nut Policy

The company has adopted and maintained what is known as the "Beech-Nut policy" and requests the co-operation of all dealers selling its products, but dealing with each customer separately. In order to secure such co-operation and to further the policy the company acts as follows:

1. Issues circulars, price lists and letters to the trade generally showing suggested uniform resale prices, both wholesale and retail, to be charged for its products.
2. Requests and insists that the selected jobbers, wholesalers and retailers sell only to such other jobbers, wholesalers and retailers as have been and are willing to resell at the prices so suggested by the company, and requests that they desist from selling to others who fail to resell at the fixed resale prices.
3. Makes it known broadcast to such selected jobbers, etc., whether sold by them direct or not, that if they, or any of them, fail to sell at the resale prices suggested by the company, it will absolutely refuse to sell further products to them.

How It Carries Out the Policy

In carrying out this policy the company refuses to sell to any of the classes who fail to maintain the fixed resale prices in every particular. And it refuses to sell the so-called mail order houses engaged in interstate commerce on the ground that these firms frequently sell to others who resell to such mail order houses. It refuses to sell all so-called price-cutters. It maintains a large sales force of specialty men who call upon the retail trade and solicit orders therefrom to be filled through jobbers and wholesalers; but its salesmen are instructed to and do refuse to accept any such "turnover" orders to be filled through jobbers or others who themselves sell or have sold at less than the suggested resale prices, and in such cases the salesmen request the retailer to name other jobbers.

How Violators of the Policy Are Detected

The company has utilized a system of key numbers or symbols stamped or marked upon the cases containing its products, thus enabling it, for any purpose whatsoever, to ascertain the identity of the distributors from whom such products were purchased. And when instances of price-cutting have been reported the company investigates through its salesmen and representatives, who are able to trace the price-cutters from whom the goods were obtained as well as the distributors from whom price-cutters have purchased the products; and thereafter the company has refused to supply all such dealers with its products.

Blacklisting Violators or Undesirable Customers

Further, the company maintains card records containing the names of thousands of jobbing, wholesale and retail distributors, and in furtherance of its refusal to sell to price-cutters has listed upon these cards, bearing the names of such distributors who do not maintain the fixed prices, the words "Undesirable—Price-Cutters," "Do not sell" or D.N.S., or expressions of like character to indicate that such distributors were not to be sold its goods in the future for failure to maintain the fixed prices, or selling to others who so failed. And when a jobber or other has been entered in the card records as one to whom shipments should not go forward, the company notifies those jobbers, wholesalers, etc., who supply the distributor, of this fact, and also notifies its specialty salesmen, and gives similar notices to such jobbers, wholesalers and retailers and to its specialty salesmen when reinstatements are made in its list of "selected" jobbers, wholesalers and retailers.

What the Circuit Court of Appeals Found

In passing on this case the federal Circuit Court of Appeals was of the opinion that the only difference between the price-fixing policy condemned as unlawful by the Supreme Court in Miles Medical Co. vs. Park & Sons Co. (31 Sup. Ct., 376), and the price-fixing plan embodied in the Beech-Nut policy was that in the former case there was an agreement in writing, while in this case the success or failure of the plan depended upon a tacit understanding with purchasers and prospective purchasers. It believed there was no difference between a written agreement and a tacit understanding in their effect upon the restraint of trade, yet it regarded the case as governed by the decision in United States against Colgate & Co. (39 Sup. Ct., 465), and accordingly held that the commission had exceeded its powers in making the order appealed from by the Beech-Nut Co.

Acts Analyzed and Distinguished in Cases

In the Colgate & Co. case the indictment charged a violation of the Sherman act prohibiting monopolies, contracts, combinations and conspiracies in restraint

of interstate commerce. But on the facts showing what the company had done in maintaining the resale prices of its products the Supreme Court held that such had amounted only to the exercise of the right of the trader or manufacturer, engaged in private business, to exercise his own discretion as to those with whom he would deal and to announce the circumstances under which he would refuse to sell; and that this was one's undoubted right and no crime had been committed.

In a subsequent case to Colgate, in United States vs. Schrader's Son, Inc. (252 U. S., 85), the manufacturer was charged with having sold to manufacturers in several states under an agreement to observe certain resale prices fixed by the vendor. The Colgate case was cited as upholding this company's right so to agree but in distinguishing the two cases and holding the manufacturer in the latter case guilty, the court pointed out that the indictment in the Colgate case failed to charge that the company made agreements, either express or implied, which undertook to obligate the buyers to observe specified or fixed resale prices. The doctrine established in the Miles Medical case, that it was unlawful under the Sherman act to attempt to destroy the dealers' independent discretion through restrictive agreements, is not in conflict with the undoubted right of a manufacturer to specify resale prices and refuse to deal with anyone who failed to maintain the same, as recognized in the Colgate case.

The Supreme Court Announces the Law as Established

These decisions have settled the law in this country that in prosecutions under the Sherman act a trader is not guilty of its violation who simply refuses to sell to others, and he may withhold his goods from those who will not sell them at the prices which he fixes for their resale. He may not, consistently with the act, go beyond the exercise of this right, and by contracts or combinations, express or implied, unduly hinder or obstruct the free and natural flow of commerce in the channels of interstate trade.

The Unfair Methods of Competition

The above-stated doctrine is applied in the Beech-Nut case only in so far as it shows a public policy to be considered in determining what are unfair methods of competition, which the Federal Trade Commission is empowered to condemn and suppress. The Federal Trade Commission act was intended to supplement the Sherman and Clayton anti-trust legislation, and the Beech-Nut suit was begun under it. The commission is given authority after a hearing to make orders to compel the discontinuance by an individual, firm or company of any "unfair methods of competition."

What are "unfair methods of competition" Congress has thought best to leave without precise definition, and to have each case determined upon its own facts, owing to the multifarious means by which it is sought to effectuate such schemes. Subject to judicial review of its decrees and orders the commission has the determination of all such schemes and practices. But it is for the courts, not the commission, ultimately to determine as matter of law what the phrase includes. In another case (253 U. S., 421) it is said by the Supreme Court that the words "unfair methods of competition" are clearly inapplicable to practices never heretofore regarded as opposed to good morals because characterized by deception, bad faith, fraud or oppression, or as against public policy because of their dangerous tendency unduly to hinder competition or create monopoly. The act was certainly not intended to fetter free and fair competition as commonly understood and practiced by honorable opponents in trade, the court says.

The declaration of public policy under the Sherman act permits a trader to refuse to sell goods to persons who will not sell at stated prices. But in the recent Beech-Nut case the system of merchandising was found to go far beyond this, being against public policy because of "its dangerous tendency unduly to hinder competition or to create monopoly." This "dangerous tendency" is another indefinite phrase, if not a "dangerous" one. The decision is by a majority of the court, five to four.

The opinion states that the Beech-Nut system of merchandising constitutes a scheme which restrains the natural flow of interstate trade which it has been the purpose of all the anti-trust acts to maintain. It says that in its practical operation it necessarily constrains the trader, if he would have the products of the Beech-Nut Co., to maintain the prices "suggested" by it. If he fails to do so, he is subject to be reported to the company either by special agents, numerous and active in that behalf, or by dealers whose aid is enlisted in maintaining the system and the prices fixed by it. Furthermore he is listed as "Undesirable—Price Cutters," to whom goods are not to be sold, etc. From this course of conduct the court concludes that competition among retail distributors is practically suppressed, for all who would deal in the company's products are constrained to sell at the suggested prices. Nor is this conclusion overcome by the fact that the merchandising conduct of the company does not constitute a contract whereby resale prices are fixed, maintained or enforced. The specific facts found show suppression of the freedom of competition by methods in which the company secures the co-operation of its distributors and customers, which are quite as effectual as agreements express or implied intended to accomplish the same purpose. By these methods the company, although selling its products at prices satisfactory to it, is enabled to prevent competition in their subsequent disposition by preventing all who do not sell at resale prices fixed by it from obtaining its goods. The authority and power of the Trade Commission to order a discontinuance of such trade practices is undoubted.

Forest Products Laboratory Publishes Decennial Record

A complete report of the proceedings of the decennial celebration held at the Forest Products Laboratory in July, 1920 (see Chem. & Met. Eng., vol. 23, p. 270, Aug. 18, 1920), forms part of an attractively printed and handsomely bound volume which has just been published by the Decennial Committee under the chairmanship of Howard F. Weiss.

The first part of the book traces the origin of the Forest Products Laboratory and then treats of its growth, organization, equipment, personnel, its pre-war research, war work and plans for future research. There are also chapters on the financial value of research results and on how to use the laboratory.

Copies of this valuable record of the work of the Forest Products Laboratory may be obtained from the Director for $1.75.

Executives of the Future

By J. J. Lawton

ONE of the most serious problems with which the factory executive always has to deal, in bad times as well as in good, is that of finding capable assistants. How little does the typical executive realize this fact! If times are good he wants men on whom he can depend to get a maximum yield from the plant. In bad times he needs men who will keep the cost of production down to a minimum.

The policy of the average manufacturing plant of today is to drop competent men when production lags for want of a market, and then to import executives when the need arises. That is, they obtain men from outside the organization to fill positions that rightly belong to those who have helped build it up. Such importations are likely to play havoc with the morale of the staff, which usually includes a few who have forged their way along by sheer persistence and force of character. However, it may be said that in general these men lack the breadth of view and general grasp of the scope of the business as a whole that would render them efficient executives. Of course there are exceptions: men who in sticking to their jobs have had the intelligence to learn the scientific principles underlying the development of the industry, but these are rare. Many reach their saturation point of efficiency long before they gain the top. After that their competency dwindles steadily as they ascend.

Executives Need a Course to Fit Them to Train Others

Modern business lays great stress on the training and education a young man should have before he is graduated into the school of commerce. When these young men do not come up to the mark in industry it is customary to blame the colleges and universities for their defective curriculum, or for turning out a poor class of graduates. Instead of this, however, the fault should be laid at the door of our modern executives, so called. It is they who are in need of a thorough course of training in industrial pedagogy which would fit them to train others in turn—to develop young material into competent assistants who ultimately will become successors to themselves. In this case the benefits of experience would manifest themselves and many plants would not be standing still, as they are today.

A young man, after leaving college, enters some corporation or plant. In most cases he is started at the foot of the ladder, in the "submarginal" class. And there, as a rule, he stays. True, there are companies with the vision and practical good sense to train their young men to become "supermarginal" in their respective lines, but these are the exception. In general the young chemist or engineer receives from his superiors no help which would enable him to climb, the usual policy being to keep him on any routine work in which he has shown himself to be proficient.

It is our engineers and chemists who should control production and manage our industries, and not our corporation lawyers and bankers with lucrative salaries who, with a stroke of the pen, can stop all research work, thus thwarting progress and throwing thousands of chemists and engineers out of employment. It is only a matter of time when these conditions must be changed. In order to compete with European industries, research work must go on, unhampered. Otherwise our chemical industries will disappear, and only a few monopolies will remain.

Ours is still to some extent a new country. Its opportunities have been so varied and numerous that ability in the rough has been sufficient to make good. But the day of untutored success in business is passing. The untrained man has less and less chance daily in obtaining the best places. The rough diamond who molded raw new-country conditions with inborn shrewdness is giving way to the smooth, well-read man, who trains his future executives so that they, in turn, will carry on the policy of wisdom with the men under them. Organized training on the part of our executives will develop the breadth of vision, the fertility of resource, demanded by latter-day business. In a word, a general realization of the need of wider perception and finer initiative on the part of our executives is bound to produce admirable results in industry. And it is a matter of vital importance to the stockholders—in the long run.

The Early Bird Certainly Gets the Worm in the Oil Fields

A very interesting report which will shortly be published by the U. S. Bureau of Mines states that delay in drilling property in a field that is being worked often results in a loss of 50 per cent of the possible production of a well. The report is based on studies by one of the engineers of the bureau in the Oklahoma, Louisiana and California fields. Many examples are given where a delay in the time of drilling was responsible for a loss of several thousand barrels per acre. Two wells exactly similar in every respect except that one was drilled nearly a year later than the other showed a difference of 53 per cent production per acre. This was in the Adair pool in Oklahoma. It has now become an axiom of the oil fields that a man must drill or be prepared to accept his loss with good grace.

An interesting analogy exists between the game laws of England and the oil fields. A deer may run across many pieces of property, but it finally belongs to the man on whose property it is killed. So it is in the oil fields. There is no way of storing oil under ground and you may have oil under your property, but it will come up through your neighbor's well unless you have one too.

Methods of Extinguishing Zinc Dust Fires Studied by the Bureau of Mines

Serial Report 2,335, issued last month by the Bureau of Mines, deals with the subject of zinc dust fires. Piles of zinc dust which are burning offer many difficulties. Water or other liquids when thrown on such a pile explode and scatter the burning powder. In addition, water will decompose, giving its oxygen to the zinc and setting free hydrogen, which of course aids the combustion.

In all, five extinguishers were used—water, sodium carbonate solution, carbon tetrachloride, silicon tetrachloride and a frothy mixture. The frothy mixture extinguished the fire most quietly and effectively. A large fire was then tested with the foam extinguisher. The fire was smothered effectively, but the pile retained its heat for several hours, so that the foam had to be left in place for some time to avoid rekindling. This objection would be more and more serious as the size of the pile increased, but the frothy mixture proved easily the best of the extinguishers tested.

New Aluminum Alloys of High Strength

Digest of Eleventh Alloys Research Report to the Institution of Mechanical Engineers—Important Properties of "A" Alloy (77:20:3 Al:Zn:Cu)—Another Alloy Has an Ultimate Strength of 91,000 Lb. Per Sq.In. With 9 Per Cent Elongation

THE tenth of a notable series of reports to the Alloys Research Committee, British Institution of Mechanical Engineers, was published about 8 years ago. Since that time the investigation of the light alloys of aluminum has been greatly expanded and increased in scope. The original plans contemplated a systematic investigation of the whole field of aluminum alloys, and the eighth, ninth and tenth reports dealt with the aluminum-copper, aluminum-copper-manganese alloys, and the aluminum-zinc alloys respectively. The war emergency, however, made the development of light alloys a national necessity. Previous experience of the members and investigators of the committee, in part unpublished, furnished an excellent foundation for the extensive investigation of the most promising aluminum alloys, an inquiry which was undertaken at once. Publication has now been made of the eleventh report, prepared by Messrs. Rosenhain, Archbutt and Hanson in collaboration with other members of the staff of the National Physical Laboratory at Teddington, England, and with the co-operation of a number of English industrial concerns and other laboratories engaged in the study of aluminum alloys for war purposes.

The eleventh report, from which these notes on new alloys have been taken, contains 256 pages of text and includes 171 figures. The authors confess at the outset that the wealth of data at their disposal and the demands of conciseness permit only a very sketchy treatment of the subject. It includes, therefore, only the more important phases of the investigation, and with only sufficient detail to give a clear understanding of the results and conclusions reached.

Cast Alloys

Twenty of the ternary alloys containing up to 4 per cent copper and 30 per cent zinc similar to those described in the tenth report were studied in the form of both sand and chill castings. The tensile strength was found to increase with increasing content of zinc, but variation of the copper content from 1 to 3 per cent made no substantial difference. With 15 per cent zinc the strength in sand castings was of the order of 30,000 lb. per sq.in.; tensile strengths as high as 44,000 lb. per sq.in. were obtained by increasing the zinc content to about 30 per cent. There are, however, certain inherent defects in these alloys from the commercial standpoint. High strength produced by a high zinc content (25 per cent) is accompanied by a relatively high density (3.2 as compared with 2.7 for pure aluminum), the alloys are hot-short, and the elongation is low. Fifteen per cent of zinc seemed to be about the practical limit, and a commonly used specification known as "L5" called for 12.5 to 14.5 per cent of zinc and from 2.5 to 3 per cent of copper.

These zinc alloys showed the phenomenon of aging to a marked degree. On standing at room temperature there is a substantial increase in the strength, amounting to about 30 per cent in the course of 7 to 9 months; this gain in strength is accompanied by a decrease in elongation. However, the marked loss in strength of these alloys at elevated temperatures, together with other properties, indicates a limited field of usefulness.

Alloys for Use at High Temperatures

As just indicated, the zinc alloys show a serious loss in strength as their temperature is raised. The importance of the use of aluminum alloys as pistons of airplane engines and automobiles and in other places where they are subjected to elevated temperatures made it essential to find alloys suitable for such duty. Considerable effort was spent on this problem. As a step in this investigation the strength of cast aluminum-copper alloys containing 6, 8, 12 and 14 per cent copper was investigated at temperatures up to 350 deg. C. At a temperature of about 200 deg. C. there was no significant difference in the strength of all four alloys as chill-cast. At the higher temperatures, of 300 and 350 deg. C., there is a marked advantage in favor of the alloys containing 12 and 14 per cent copper. The 92:8 Al:Cu alloy, chill-cast, changed in strength from about 18,400 lb. per sq.in. at 20 deg. C. to 7,500 lb. per sq.in. at 350 deg. C. Similarly the 86:14 aluminum-copper alloy had a strength of about 22,000 lb. per sq.in. at 20 deg. C., and 10,700 lb. per sq.in. at 350 deg. C.

It was found that manganese was a valuable addition in increasing the strength of aluminum alloys at high temperatures. The maximum improvement was secured with 1 per cent manganese. Aluminum-copper-manganese alloys containing 1 per cent manganese were actually stronger at 250 deg. C. than at room temperature; the increase amounted to about 2,000 to 2,500 lb. per sq.in. Above 250 deg. C. the strength fell off at the same rate as with the Al:Cu alloys without manganese. There was some practical difficulty in the use of the 85:14:1 Al:Cu:Mn alloy in the foundry, so other alloys containing iron, molybdenum, tungsten chromium or vanadium were investigated. None of these alloys proved entirely satisfactory.

The effect of nickel was then investigated and it led to results of first importance. One to 3 per cent Ni was tried in combination with from 8 to 12 per cent Cu. It exerted a beneficial effect, but there was still a marked decrease in strength at moderate temperatures. Magnesium was then added in addition to copper and nickel, whereupon a marked improvement was obtained. Investigation of the limits of the three components showed the 4 copper, 2 nickel, 1.5 magnesium alloy (remainder aluminum) to be the best combination, and this alloy, known as "Y" alloy, was

[1]By the Institution of Mechanical Engineers, Storey's Gate, St. James' Park, London, S. W. Price, £2 2s.

made the subject of an extensive investigation. It was also found suitable for forging and rolling. The preparation, treatment and properties of "Y" alloy will form the subject of another article in this journal, as its importance seems to warrant separate treatment.

Casting Contraction

The total linear contraction on casting was determined for a number of alloys. As shown in Fig. 1, the method consisted of casting a ½ x 1-in. bar 10 in. long in a steel yoke, and after cooling measuring the contraction. The highest contraction was noted in the

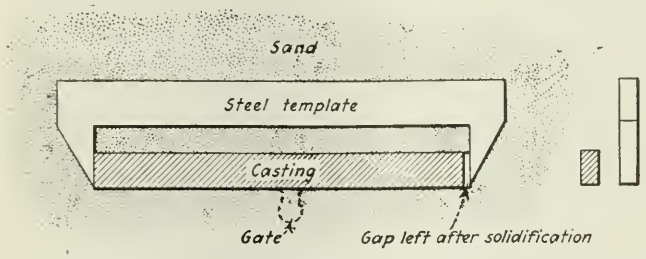

FIG. 1—METHOD FOR DETERMINING LINEAR CONTRACTION

binary alloy with 15 per cent zinc and amounted to 1.42 per cent. The 85:14:1 Al:Cu:Mn alloy was among the lowest, with a contraction of 1.21 per cent. No differences in the solid shrinkage were observed which could account for the marked differences observed in casting the different alloys.

Thermal Conductivity

One marked advantage which the aluminum piston offers lies in the high thermal conductivity of the metal. It is important, therefore, that the alloy selected be favorable from this standpoint also.

A series of determinations of the thermal conductivity of certain of the aluminum alloys was carried out by Dr. E. H. Griffiths of the heat department of the National Physical Laboratory. As far as is known to the abstractor, these are the only thermal conductivity data available on aluminum alloys, and a few are reprinted in Table I. The full report contains information

TABLE I—THERMAL CONDUCTIVITY OF SOME ALUMINUM ALLOYS

on both sand and chill castings, but the data are complete only for chill castings and since there was no significant difference the values for the latter are taken for comparison.

Heat-Treatment of Castings

Although the opinion was commonly held that castings of the composition of duralumin (4 Cu, 0.5 Mn, 0.8 Mg, 0.5 Si, remainder Al) could not be materially improved by heat-treatment, nevertheless the authors satisfied themselves that by the selection of the proper conditions a very desirable improvement could be obtained. Their tests showed that in chill-cast test-bars containing up to 4 per cent of copper all of the CuAl, could be brought into solid solution by 3 days' heating at a temperature between 450 and 520 deg. C. Only a trace of undissolved CuAl, remained in a sample containing 4.5 per cent copper. Such annealing increased the strength of the 4.5 per cent copper alloy from 21,100 to 33,600 lb. per sq.in. It is not stated whether the sample was quenched or not after heating. It was also found that temperatures as high as 530 deg. C. could be successfully used for heat-treating copper-aluminum castings. Alloy "Y" proved exceptionally amenable to heat-treatment.

Wrought Alloys

In investigating the working of aluminum alloys by forging, rolling, extrusion and drawing, the first series investigated was the ternary system Al:Zn:Cu. Alloys containing up to 25 per cent zinc and 4 per cent copper were cast in cylindrical billets, 3 in. in diameter and 19 in. long. It was first attempted to roll these experimental billets at a plant of the British Aluminium Co., but difficulty was experienced because the regular practice was not suitable for rolling such hard alloys. Steps were taken, therefore, to install an experimental mill at the National Physical Laboratory.[2] The chief difficulty encountered was the cracking of the ingots during the hot-rolling, and surface defects and edge cracking in the finished sheet. Information gained in preliminary rollings, however, indicated that the 3 copper-20 zinc alloy was about the most promising of the lot and its properties were sufficiently good to warrant further investigation.

Development of Alloy "A" or "3/20"

First it was attempted to roll the alloy containing 3 per cent copper and 25 per cent zinc into bars and rods. About fifty of the 3-in. billets were tried with preliminary forging of various degrees, with working temperatures from 400 deg. C. down to 300 deg. C., and with variations in the rolling speed and reduction per pass without eliminating the serious cracking. Although the authors believe that the "3/25" alloy could have been rolled satisfactorily after a sufficient study of the problem, the urgent need for light alloys caused them to center their efforts on the somewhat softer "3/20" alloy, which has been christened "A." Between June, 1915, and March, 1916, they demonstrated to their satisfaction that this alloy could be satisfactorily produced. As a result of their extended experiments they concluded that most of the cracks and defects developed on rolling could be traced back to the original ingot and only when proper attention was given to the casting of the ingot could a satisfactory product be assured. Slow pouring of billets was adopted, with the mold tilted at an angle of about 45 deg. The object in pouring slowly was to permit solidification of the metal in the mold to proceed at about the same rate as the liquid metal was added. Thus shrinkage cavities were largely avoided and little or no "heading up" of the ingot was required. Molds were also used at a relatively low temperature (100 deg. C.).

In addition to the necessity of careful control of the casting of the ingots, the authors found it necessary to give "A" ingots a forging treatment. Hot-forging at 400 deg. C. was followed by an intermediate annealing

[2]To be described in some detail in the subsequent article on "Y" alloy.

and another forging operation together with a final annealing for 1 hour at 450 deg. C. before rolling. The object of the annealing was to obtain complete absorption of the free $CuAl_2$ and a more homogeneous structure. It is also necessary to lubricate the rolls properly. When it was attempted to cast and roll slabs 7 x 14 x 1½ in., more difficulties were encountered. Cracking and surface defects were quite common. The fact that they could be largely eliminated by machining the surface of the ingot to a depth of about ⅛ in. before rolling demonstrated again that the cast surface of the ingot was the source of part of their difficulties, and this trouble was largely overcome by careful attention to detail.

Extrusion

In view of the early troubles in breaking down chill-cast ingots, extrusion was resorted to in order to get the metal in shape for subsequent rolling. Many of the hard alloys were successfully extruded at temperatures much lower, but requiring higher pressures than for aluminum. Longitudinal central defects leading to lamination in the extruded bars have injured the reputation of extruded bars. These defects are due to original contraction cavities in the ingot, or by drawing down portions of the skin into the bar. Such troubles were therefore eliminated by correct pouring practice—as noted above. Drawing of the rear surface of the ingot into the center of the bar can be avoided by placing a corrugated friction plate of steel between ram and billet. Alloy "A," for instance, when successfully extruded in bars 1½ in. in diameter and greater, gives tensile properties closely analogous to those of the same alloy after forging and rolling.

Overannealing

In cold-working, such as spinning of this alloy sheet, it was found that 250 deg. C. was the most satisfactory annealing temperature, as it gave the highest ductility to the annealed product. Thirty minutes' annealing at 100 deg. C. produced a noticeable softening of alloy "A" sheet, while annealing at 180 deg. C. produced the maximum softening and gave material having a tensile strength of 42,000 lb. per sq.in. and an elongation of 29 per cent in 2 in.

Experiments on the behavior of the alloys under prolonged stress led to the discovery that many of them can be seriously damaged by annealing at moderate temperatures. This type of fracture occurs between the crystals, and is very similar to "season cracking." It may be investigated by bending a strip of comparatively thin sheet into a U with about 1½ in. radius, when it acquires a permanent set. If a piece will withstand this position for several days it never undergoes failure in use—at least for 2 or 3 years.

Hot-rolled "A" alloy is entirely free of intercrystalline fracture induced by bending, if the reduction after any possible heating is 50 per cent. Such safe materials having a structure shown in Fig. 2, however, if annealed 1 hour at more than 250 deg. C., will fail in short time—the quicker the higher the anneal. High annealing produces an equiaxed structure shown in Fig. 3. Heat-treatment has so far been found inadequate to correct this liability for fracture. A low amount of "overannealing" can be cured by a moderate amount of cold-work; an excessively overannealed piece can be rendered immune from failure under the bend test only by a reduction while hot of at least 50 per cent, applied in moderate drafts.

This alloy in the form of thin sheet was suggested as a covering for airplane wings, and with this object in view the British Aluminium Co. eventually produced sheets 12 in. wide by 6 ft. long and 0.0035 in. thick. This sheet had a tensile strength of 51,000 lb. per sq.in. and an elongation of 3 per cent in 2 in., after annealing at 250 deg. C. Its low resistance to ripping seemed to be a decided disadvantage as a covering for airplane wings.

TABLE II—PHYSICAL PROPERTIES OF ALLOY "A" (77 Al, 3 Cu, 20 Zn)

Density = 3.1

Material	Condition	Yield Point, Lb./Sq. In.	Tensile Strength, Lb./Sq. In.	Elongation, Per Cent in 2 In.
Rod; 1½ in. dia.	Hot-rolled	39,400	59,100	17
Rod; ⅞ in. dia.	Hot-rolled	41,000	60,500	21
Sheet; 0.104 to 0.048 in. thick	Hot-rolled	37,900	61,000	19
Sheet; 0.05 in. thick	Hot-rolled and aged 4 years	60,500	74,000	16
Sheet; 0.104 in. thick	Hot-rolled and annealed at 200 deg. C.	27,600	49,800	24–28
Sheet; 0.119 to 0.048 in. thick	Cold-rolled	58,300	66,500	11

Tests of a wide variety were made on the alloy and included compression, fatigue (alternating stress), notched bar impact, at ordinary and at high temperatures. Exposure to temperatures as low as —185 deg. C. had no deleterious effect on the alloy. The properties of this alloy in various forms and after different treatments are summarized by characteristic tests in Table II.

Development of Alloy "E"

Concurrently with the development of alloy "A" the possibility of still further improving it by the addition of magnesium and by heat-treating was investigated. It was found impossible to roll or forge these alloys containing 0.25 to 0.5 per cent magnesium. If the alloy were first extruded, however, it could be readily hot-rolled. Some experimentation led to an alloy having the following nominal composition and known as alloy "E."

	Per Cent		Per Cent
Copper	2.5	Manganese	0.5
Zinc	20.0	Iron (not over)	0.20
Magnesium	0.5	Silicon (not over)	0.20

Tensile tests of this material in the form of a ½-in. rod showed strengths of over 80,000 lb. per sq.in., with an elongation of 12 per cent in 2 in. These properties merited further development, and the rolling of sheet was investigated.

Again, the cast slabs gave trouble. One improvement

FIG. 2 (AT LEFT)—HOT-ROLLED ALLOY "A" Annealed at 250 deg. C. Immune from intercrystalline cracking. × 125.

FIG. 3 (AT RIGHT)—ALLOY "A" Intercrystalline crack in overannealed structure. × 125.

was made by discarding the use of the rich 20 per cent magnesium-aluminum alloy for the addition of magnesium and adding the pure magnesium metal in the form of a couple of sticks just before pouring. Furthermore, it was found necessary to carry out the preliminary forging at a low temperature (300 deg. C.) and to break down the slabs in the rolls at about the same temperature. After a 50 per cent reduction in thickness was effected, a higher rolling temperature (400 deg. C.) was employed. Edge-cracking was always serious with these alloys and the scrap loss high; machining the surface of the ingots had to be done. Typical tests of sheet rolled from this alloy are given in Table III.

TABLE III—PHYSICAL PROPERTIES OF ALLOY "E"—18-GAGE SHEET

Condition	Yield Point, Lb./Sq. In.	Tensile Strength, Lb./Sq. In.	Elongation, Per Cent in 2 In.
As hot-rolled	59,000	70,400	15
As hot-rolled	55,600	73,000	16
Annealed at 250° C	32,500	56,700	20
Quenched from 250° C. and aged	30,700	52,200	22
Quenched from 350° C. and aged	61,200	81,800	10
Quenched from 400° C. and aged	62,300	86,700	9
Quenched from 400° C. and aged	68,400	87,600	11

Although remarkably high tensile strengths were obtained after quenching and aging, the ductility was rather low. By reducing the magnesium content to 0.25 per cent, or by reducing the magnesium to 0.25 per cent and increasing the silicon to 0.5 or 1.0 per cent, the ductility was materially improved with only a small reduction in tensile strength.

The highest strength for any aluminum alloy given in this report was obtained with alloy "E" after extrusion, hot-rolling, quenching from 400 deg. C. and aging. It then had a strength of 91,100 lb. per sq.in. and an elongation of 9 per cent in 2 in. Alloy "E" is a typical duralumin composition except for rather low copper and the addition of 20 per cent zinc.

Both alloys "A" and "E" showed a serious loss in strength at slightly elevated temperatures (150 deg. C., for example), so that alloy "Y," which in castings had proved so satisfactory, was developed as a rolling alloy. Its properties proved to be quite similar to those of alloys of the duralumin type except that alloy "Y" maintained these properties somewhat better at elevated temperatures.

In summarizing and comparing the properties of these alloys the authors put alloys "A" and "Y" in a class by themselves as regards ease of production. They feel, however, that alloy "E" and its modifications possess certain properties which might for certain purposes discount the manufacturing difficulties. The possibility of season cracking with alloy "A" is one which should be considered. All of these alloys except "Y" are quite susceptible to corrosion and would need proper protection. They are also somewhat denser, which is a disadvantage for some purposes.

Permanance of the Alloys

The literature has contained references from time to time concerning the deterioration of certain aluminum alloys on long standing. The fact that the zinc alloys and alloys of the duralumin type undergo an internal change at ordinary temperatures raises the question as to what the ultimate course of these changes might be and what reliance might be placed on the stability of this material. The authors had this point in mind and were able to bring data collected over a period of 10 years as evidence to the reliability of these alloys, and the conclusions are quite reassuring. While the alloys studied (and more particularly duralumin, as it was the oldest of these alloys on which they had made tests) showed certain changes in the direction of increased hardness and strength, the ductility was only slightly diminished and they were sufficiently stable in dimension and length for all practical purposes.

Cast specimens of "L5" (2 to 3 per cent copper and 12 to 15 per cent zinc) showed an increase in tensile strength of about 30 per cent and a decrease in elongation from about 2 to 3 per cent to 1 per cent after a period of 10 months.

Rolled alloys increased in hardness on aging with increase of the zinc content. A 1¼-in. diameter hot-rolled rod (2 per cent copper and 15 per cent zinc), had a Brinell hardness number of about 94 at 7 months after production; 10 years later the hardness had increased to 150. A sample of sheet from alloy "A" (3/20) 0.103 in. in thickness had a strength of 57,500 lb. per sq.in. and an elongation of 14 per cent, as rolled; after 4½ years its strength was 64,300 lb. per sq.in. and its elongation 10 per cent. The aging was more marked in thin sheet than in thick sheet.

Other alloys were of relatively recent development and results extending back much over a year were not available. Some samples of duralumin manufactured by the regular makers of that alloy and tested in 1911 and again in 1921 showed an increase from 60,500 to 63,200 lb. per sq.in. in strength and a reduction in elongation from around 18 per cent to about 15 per cent. The yield point increased from 38,500 to 46,100 lb. per sq.in. This material is, of course, not typical of present-day production, but the results are nevertheless of value; they indicate no serious deterioration in the properties of the alloy.

Duralumin, as first suggested by Wilm, contained 3 to 4 per cent of copper, about 0.5 per cent of magnesium, and iron and silicon in the proportions contained in the original ingot. The composition is fairly well standardized now on 3.75 per cent copper, 0.5 per cent magnesium, and 0.6 to 0.7 per cent manganese.

Alloys of the duralumin type and "Y" alloy, when heat-treated were the best of the alloys described as regards resistance to corrosion. Alloys "A" and "E" were very seriously corroded by prolonged contact with even weak saline solutions like tap water, and would require adequate protection where exposed to the weather or similar corrosive environments.

Constitution of the Alloys

Development of the alloys described was accompanied by a study of their constitution and microstructure, and this theoretical attack of the problem was indispensable. Equilibrium relations in the ternary system copper-zinc-aluminum were determined in continuation of the plan adopted in the tenth report. Copper-aluminum binary diagram was completed by determining the solubility of copper in solid aluminum; at 540 deg. C. 5 per cent of copper was found to be soluble in aluminum and at 20 deg. C. this had decreased to about 3 per cent. In the ternary system with zinc, no new compounds were found to exist and the principal phase in the alloys with low copper and moderately high zinc is a solid solution of copper, zinc and aluminum.

Although the iron-aluminum system had been investigated by Gwyer, the diagram was not complete at the aluminum end. It had been found that the compound

$FeAl_2$ forms a eutectic with aluminum which contains 2 per cent iron and melts at 648 deg. C. $FeAl_3$ was found to be practically insoluble in solid aluminum, and the purest aluminum they examined still showed the presence of free $FeAl_2$.

Aluminum and silicon form a eutectiferous series with a eutectic at about 10.5 per cent silicon. The authors state that silicon is sparingly soluble in solid aluminum; they were able to bring 1.5 per cent into solid solution, and the solubility did not appear to decrease appreciably as the temperature was lowered. They note that when the silicon alloys are attacked with strong oxidizing agents, as in the chemical analysis of such alloys, part of the silicon resists attack and may be determined as free silicon, while part is oxidized and determined as silica. The part which is oxidized to SiO_2 is supposed to be the silicon which was in solid solution or in combination in the aluminum, while the portion determined as silicon existed as free crystals of silicon in the alloy.

The iron-silicon-aluminum system is important, as iron and silicon occur as impurities in all aluminum made by present-day processes. Alloys containing silicon up to 8 per cent and iron up to 8 per cent have been investigated. Fig. 4 shows a new constituent, identified as constituent "X," but its composition was not determined. The constitution of the ternary alloys containing up to 4 per cent silicon has been established, and is illustrated by a number of diagrams.

An investigation of the aluminum-magnesium diagram by Hanson and Gayler has already been published in the *Journal* of the Institute of Metals. The ternary system silicon-magnesium-aluminum has been investigated up to 11 per cent silicon and 35 per cent magnesium; equilibrium relations are quite complex and the full report must be studied for a complete understanding of the alloys. A compound Mg_2Si was identified as blue crystals of striking appearance. This compound, Mg_2Si, and aluminum form a eutectic freezing slightly below 600 deg. C., as in typical binary systems, and this eutectic contains about 13 per cent Mg_2Si (8.2 per cent magnesium and 4.8 per cent silicon). (See Fig. 5.) At the eutectic temperature about 1.6 per cent Mg_2Si (1.0 per cent magnesium and 0.6 per cent silicon) is soluble. The solubility decreases very appreciably at lower temperatures and at 30 deg. C. not more than 0.54 per cent Mg_2Si is soluble; even this latter figure is probably somewhat high.

Age-Hardening of Alloys of Aluminum With Magnesium and Silicon

The authors establish the fact that when magnesium and silicon are both present in aluminum, the alloy has the property of hardening after quenching. In order to identify the hardening effect with the compound Mg_2Si, a series of specimens was prepared in which the amount of Mg_2Si increased progressively to well beyond the solubility limits of that compound at the eutectic temperature. These samples were first forged and rolled to strips $\frac{1}{10}$ in. thick. After heating 1 hour at 500 deg. C., samples of each were quenched and other samples were slowly cooled in the furnace. After aging for 7 days the samples were tested. The results showed a progressive increase in hardness as the amount of Mg_2Si was increased up to the limit of solubility; thereafter the hardness remained practically constant. Other tests with alloys containing either silicon or magnesium in excess of the ratio to form Mg_2Si were made and confirmed this conclusion. All of the alloys examined reached a maximum hardness in the neighborhood of the solubility line.

These results convinced the authors that the aging of these alloys is due to the fact that the Mg_2Si, by quenching, is retained in an unstable form, such as a solid solution, and that this reverts to a more stable form on standing. Gradual hardening is believed to be the result of the tendency to form particles of Mg_2Si of sub-microscopic size. No visible change is revealed by the microscope. The evidence indicates that the alloys in the quenched and age-hardened condition are permanent—that is, in stable equilibrium—at ordinary temperatures. Their theory of the mechanism of the hardening of duralumin is quite similar to that developed independently by Merica, Waltenberg and Scott at the Bureau of Standards. The American investigators attributed the hardening largely to the compound $CuAl_2$, whereas the authors state that $CuAl_2$ is not able to produce hardening of the order found in the heat-treatment of such alloys, and that the part corresponding somewhat to that played by cementite (Fe_3C) in steel is played by Mg_2Si in these compounds.

Duralumin is completely hardened after about 4 days at room temperature; the greater part of the hardening occurs in the first 24 hours, however. Magnesium-silicon alloys just discussed attain complete hardness in about the same time, except one sample which contained magnesium in excess of that required to form Mg_2Si and which was not completely hardened after 12 days; the final hardness was then lower. This anomaly the authors attribute to the lowering of the solubility of Mg_2Si by the excess magnesium.

FIG. 4—ALLOY 91 : 8 : 1 Al : Fe : Si

Annealed 170 hours at 565 deg. C. Matrix of aluminum-rich solid solution; long crystal of $FeAl_3$ surrounded by an envelope of constituent "X". Etched with 10 per cent NaOH in water. × 1,000.

High aging temperatures were investigated on these same alloys, which contained silicon from 0.6 to 1.0 per cent and magnesium from 0.6 to 2.0 per cent. Improvement in strength increased with the temperature, and a maximum hardness was reached by heating at 200 deg. C. Higher aging temperatures resulted in rapid decrease in hardness and tensile strength.

The effect of copper, zinc and nickel on the age-hardening of aluminum as effected by the compound Mg_2Si was studied. A series of alloys, each containing 3 per cent of copper and magnesium silicide varying from the minimum corresponding to the silicon content of the alloy up to 3 per cent, was prepared. They were all heated at 500 deg. C.; one sample of each was quenched and a second cooled slowly in the furnace.

They were then tested after aging 3 weeks at room temperature. Age-hardening was quite appreciable with 0.55 per cent Mg_2Si, corresponding to 0.20 silicon. The maximum effect was reached with 0.9 per cent Mg_2Si (0.35 per cent silicon); this amount corresponds to the solubility of Mg_2Si at 500 deg. in aluminum containing 3 per cent copper. They conclude that the addition of copper reduces the amount of Mg_2Si which can be dissolved and hence reduces the maximum hardening effect which it is possible to obtain. No advantage was found in increasing the Mg_2Si beyond 0.9 per cent in the presence of 3 per cent copper. Reheating the quenched alloys for 1 hour at 50 or 100 deg. C. showed an inappreciable increase in hardness, while a slight softening was observed in the alloy containing very low Mg_2Si after heating at 150 deg. C. All except this latter sample showed a marked increase in hardness at 200 deg. C. but at 250 deg. C. the hardness decreased.

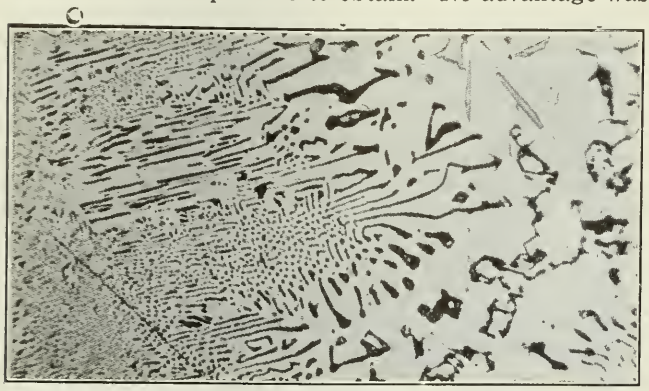

FIG. 5—CAST ALLOY 86:10:4 Al:Mg:Si
A little primary aluminum, but the alloy is largely a binary eutectic complex of Mg_2Si and aluminum. Unetched. × 125.

Alloys containing 15 per cent zinc instead of 3 per cent copper showed little increase in strength on aging; the maximum effect was obtained at 150 deg. C.

Alloys containing 3 per cent of nickel indicated that this element had less effect on the solubility of Mg_2Si than either copper or zinc. The maximum hardening was obtained with about 1.3 per cent Mg_2Si, and after heating at 200 deg. C.

In order to study the hardening of copper-aluminum alloys after quenching from a high temperature, a series of ten alloys containing from 0.5 to 5 per cent copper were cast, forged and quenched from 500 deg. C. After 5 days' aging, a small increase in hardness was observed, but in no case did Brinell hardness increase more than 10. The samples were then reheated for 1 hour at various temperatures. In the alloys containing 3 to 5 per cent copper, a somewhat greater hardness was obtained at 205 deg. C., and a still greater improvement after heating 2.5 hours. The maximum hardness would be obtained with an alloy containing 4.5 per cent copper, heated at 500 deg. C., quenched and subsequently reheated for about 3 hours at 205 deg. C. The amount of this hardening is considerably less than in similar alloys containing Mg_2Si.

To alloys containing 4 per cent copper and 4 per cent copper with 0.5 per cent manganese, varying amounts of magnesium silicide were added. With the 4 per cent copper alone, 0.55 per cent Mg_2Si gave a tensile strength of about 52,000 lb. per sq.in. after heating, quenching and aging for 4 days; reheating at temperatures above 100 deg. C. resulted in a loss in strength, although the elongation was improved up to 150 deg. C. With 4 per cent of copper and 1.35 per cent Mg_2Si (0.85 per cent magnesium and 0.5 per cent silicon), the strength, after quenching and aging, was 55,000 lb. per sq.in. The strength was increased to about 57,000 lb. per sq.in. by reheating at 200 deg. C.

In the alloys containing 0.5 per cent manganese and 4 per cent copper, a decided increase in strength was obtained by increasing the magnesium silicide from 0.55 to 1.35 per cent. The maximum strength was 56,000 lb. per sq.in. with the smaller amount of Mg_2Si and about 64,000 lb. with 1.35 per cent Mg_2Si (after reheating to 175 deg. C.).

The elongation of any one of the alloys of this series is not reduced by the aging process nor by reheating at higher temperatures up to about 150 deg. C. Above 200 deg. C. the ductility decreases rapidly.

The Effect of Bomb Corrosion on the Accuracy of Calorimetric Determinations

By H. L. Olin and R. E. Wilkin
Department of Chemistry, State University of Iowa, Iowa City, Iowa

THE practice of modern combustion calorimetry properly begins with the work of Berthelot,[1] who was the first to design an instrument in which the material under examination was burned in an excess of oxygen under high pressure. His bomb, because of its heavy platinum lining, was extremely expensive; in 1892, Mahler,[2] besides improving its mechanical design, substituted a lining of enamel for the more costly material.

A calorimeter bomb embodying many of the best features of those used today was described in 1894 by Atwater.[3] Corrosion was prevented by the use of a platinum lining or in lieu of that, of a copper lining heavily plated with gold. One of these in particular withstood 300 combustions before blisters appeared in the plating and 400 before the presence of copper could be detected in the washings.

Some years ago Prof. A. H. White furnished for the use of his classes at the University of Michigan a bomb made of steel only, which gave good service by virtue of the formation of an inner coating of dense adherent scale. Later, however, Monel metal was selected to replace the steel, with more satisfactory results.

In 1915 Prof. S. W. Parr[4] perfected a new acid-resisting alloy known as Illium to replace platinum in calorimeter bomb construction. This complex combination of nine different metals has the necessary tensile strength and is extremely resistant to both nitric and sulphuric acids. The first bomb constructed of this material was in constant use in his laboratory for months without showing deterioration, and the test of time has since proved it to be the equivalent of platinum for the purpose in question.

It is evident from this brief review of the work of the authorities on the subject that the necessity for providing a non-oxidizable inner surface for the bomb has been, almost without exception, tacitly assumed. It is clear that corrosion or oxidation of the metal, which invariably involves an exothermic reaction, increases the total heat to be measured by an amount

[1] *Compt. rend.*, vol. 104, p. 375 (1887).

equivalent to the quantity of metal dissolved, and that even should the injury to the instrument be overlooked, the expenditure of time and labor for determining the metal content of the bomb washings for the purpose of applying a correction could not be tolerated.

The Nickel-Lined Bomb

Of particular interest from the standpoint of this paper was the announcement in 1909 of the design of a new calorimeter by Emerson.[5] This instrument embodies many excellent mechanical features with respect both to ease of assembly and to the admission of oxygen. As advertised in current catalogs of dealers in scientific apparatus, bomb linings of three different metals are offered—viz, platinum, gold and nickel. The latter because of its low cost has apparently proved to be the most popular, especially as it carries the unqualified recommendation of the manufacturer for general work. Concerning this point, Charles J. Emerson in a private communication writes: "The nickel linings are perfectly satisfactory for the general run of calorimeter work, as the errors involved in the use of this type of instrument are well within the limits of accuracy of the other elements entering into the determination, as, for instance, the thermometric errors and those in sampling as encountered particularly in fuel work."

In view of this radical departure from established standards, since pure nickel cannot be considered especially resistant to oxidation, the work of determining the corrosion effect on nickel was undertaken, primarily to guide the technical worker in interpreting results obtained with this type of instrument and secondarily to throw light on the general question of standards for bomb construction. Manifestly if a relatively inexpensive metal will serve for instruments used in industrial laboratories, no logical reason can be advanced for providing gold or platinum.

Experimental Procedure

The work done was divided into Series I and II. In the first, a substance or mixture of known calorific value was burned in the bomb to be tested and the discrepancies between the values calculated and those found were measured. Thus the sources of error were determined. In the second series parallel samples of coal were burned in a standard bomb in which no corrosion could take place, and also in the nickel bomb. As before, the magnitude and sources of error were studied. Calorimetric measurements were made in each case with all the care prescribed for accurate work on fuels, following in general the methods of Stanton and Fieldner[6] as given in Technical Paper No. 8 of the Bureau of Mines. The thermometer used was certified by the U. S. Bureau of Standards.

Series I.—Combustion samples for Series I were made up of standard sucrose (Bureau of Standards No. 17), with a heat value of 3,949 calories per gram, mixed with relatively small quantities of pure rhombic sulphur. According to Thomsen[7] the molecular heat of combustion of the latter plus heat of solution is 142,400 calories, and calculations were made on that basis.

After each run the bomb washings were titrated with standard alkali, then analyzed for nickel by the well-known dimethyl-glyoxime method. Runs 1-5, as shown in Table I, were made with sugar alone, and since nitrogen was the only acid element present, the formation of $Ni(NO_3)_2$ is assumed. Referring again to Thomsen's figures, we find the value 83,420 calories for $Ni\text{-}O\text{-}N_2O_5Aq$, from which the errors due to corrosion were calculated. Where sulphur was added, as in runs 6 to 18, the predominating salt is $NiSO_4$ and the computation of error was based on Thomsen's figures of 86,950 calories for $Ni\text{-}O\text{-}SO_3Aq$. It is evident, of course, that some nickel nitrate is present in the washings from these later runs as well, but inasmuch as the heats of formation of the two salts are so nearly equal the actual difference in this case amounts to only a few calories. Nickel determinations were made in each case only after filtration of the washings with a view to the elimination of any nickel oxide that might be present, thereby insuring the presence of nickel salts only.

ularly for their rather high sulphur values. Table II shows their content of non-coal substances.

The bomb used as a standard for comparison was one of the Mahler-Atwater type lined with platinum. As before, free acids were determined by titration and, since no corrosion was possible, the titer was a measure of the acids generated in the reaction. Similarly the coals were burned in the nickel-lined bomb and free acid and nickel contents of the washings were determined. Results are given in Table III.

Corrections and Sources of Error

Attention is directed to the fact that for the purpose of comparison the heat values of the coal given in columns 2 and 4 of Table III as determined by the two instruments are not corrected for sulphur. It should be noted, however, that in the regular practice of coal calorimetry a correction is invariably made for the difference between the heats of formation of the dioxide and the trioxide as they are generated in the furnace and the bomb, respectively, and for nitric acid produced. Formulated, this correction is

$$C = vk + 13w$$

where C is the number of calories, v the volume in cubic centimeters of standard alkali used in titrating the bomb washings, k a constant quantity of heat, which is a function of the strength of the standard solution, and w the weight in centigrams of the sulphur as determined separately.

* See "Methods of Analyzing Coal and Coke," Stanton and Fieldner, Tech. Paper 8, Bureau of Mines, pp. 33-34.

Inasmuch as only a small quantity of free acid remains in the washings from the nickel bomb in consequence of its reaction on the lining, as shown by comparison of columns 3 and 5, the value of v as found is too low, and the correction is consequently in error by an amount varying with the quantity of acid-forming constituents of the coal. For total error this value, which is tabulated in column 8 of Table III, must be added to that calculated for the heat of formation of nickel salts.

Any attempt to apply a correction for the heat of corrosion of the lining calculated as a function of the sulphur content of the fuel would not be feasible for the reason that with continued use the bomb becomes more and more roughened and pitted, thereby offering increasingly favorable contact to the acids present. Moreover the period between the time of ignition and that of washing the bomb must always be a variable affecting the accuracy of the correction.

It should be noted particularly that the values of absolute errors as given do not depend directly upon our calorimetric measurements, which include the reading of the thermometer, the calculation of corrections for radiation and the like, as well as the weighings and adjustments incident to a run, all of which offer opportunities for error, but upon two simple and highly accurate methods of chemical analysis—viz., the determination of nickel by the glyoxime method and the titration of an acid with a standard alkali solution. Of course, indirectly they depend upon Thomsen's work, which, however, is generally accepted.

Conclusions

In attempting to pass judgment on the merits of an instrument on the basis of results obtained in its use the matter of a standard of comparison is naturally of prime importance. A conservative estimate of the accuracy obtainable with a good oxygen bomb calorimeter is a figure well within 0.5 per cent. Naturally, this limit of accuracy assumes that operators of the calorimeter should be experienced, versed in quantitative procedure and reasonably careful.

In the opinion of the committee on coal analysis of the American Chemical Society, results obtained by a single analyst should not differ more than 0.3 per cent, while those obtained by different analysts should agree within 0.4 per cent. Reference to the accompanying tables will show errors as high as 2.5 per cent or more in the use of the nickel bomb, equivalent in the heat determination of a coal, for instance, to a mercury rise of about 0.15 deg. F. Inasmuch as no difficulty is experienced in reading accurately to 0.002 deg. F. with a Beckmann thermometer or with the Richards modification of the Beckmann instrument, it is readily seen that the inherent error of the instrument far exceeds that of the observer's eye or of the personal equation in general. It seems fair to say that greater accuracy than that obtained can be had with instruments of other types and of much lower cost or indeed by calculation from analytical data according to formulas that have been prepared for that purpose. Furthermore, the purchaser of an oxygen bomb outfit, who must make in any case a relatively large capital investment and whose use of the instrument must necessarily involve considerable care and expense, expects a fairly high accuracy. In buying a cheaper lining, therefore, he defeats his own ends.

With respect to the subject of standards in fuel technology, the growing tendency for large consumers of coal to purchase their supplies on rigid specification is increasing the demand for accurate calorimetry, inasmuch as the results must govern the question of bonus or penalty on settlement. An attitude of tolerance toward questionable technical methods naturally cannot be long maintained by either party to the transaction.

The authors wish to emphasize, in conclusion, the fact that this article is not, in general, a criticism of any particular instrument but of the use for bomb linings of nickel or any other metal so slightly resistant to corrosion as nickel proves to be.

Minerals, Earths and Clays of Latin America—II

The Natural Resources of the Central and South American Countries, Many of Which Are Now Undeveloped, May Yet Contribute Largely to the World's Supply of Manganese, Chromium, Tungsten, Vanadium, Molybdenum, Cobalt, Titanium and Zirconium

By Otto Wilson
Former Chief, Latin-American Division, Department of Commerce

THE European war and the shutting off of supplies of manganese from Russia and India resulted in an important development for the production of that mineral in Latin-American countries, especially in Brazil. The Brazilian deposits are numerous and rich and the possibilities for future production are most promising. Some of these deposits had already been exploited, since for 25 years Brazil had been exporting manganese and up to the time of the war had had a total output amounting to about 500,000 tons. Exports rapidly mounted, however, when the American steel plants called on Brazil to replace Russian and Indian ores, and in 1917 they reached their highest point, 532,856 tons, valued at $14,321,003. This amount is about all the present railway facilities can handle. In 1918 exports dropped in quantity to 393,388 tons and in value to $11,460,760. In 1919 they amounted to 205,725 tons, valued at $4,397,468, and in 1920 to 453,737 tons, valued at $8,762,479. Lack of transportation facilities is said to be the only factor that retards development.

Manganese Deposits in Brazil

The greater share of past production has come from three states—Minas Geraes, Bahia and Matto Grosso—but other deposits are known in Maranhao, Parana, Pernambuco, Rio de Janeiro, Rio Grande do Norte, Santa Catharina and São Paulo. The most important producing region is in Minas Geraes, near the iron deposits, and much of the ore is found in the same Itabira formation referred to in the preceding article of this series.[1] The chief deposits are near the stations of Lafayette and Miguel Burnier, on the Central Railway of Brazil. The leading mine of the Lafayette district, the Morro da Mina, has produced 2,000,000 tons of ore, and there is a proved reserve of 10,000,000 tons. The ore is of high grade, three analyses of the ore from the Lafayette district showing 49 to 51 per cent, 50 to 52 per cent and 50.47 per cent manganese, from 1 to 7 per cent silica, and 0.08 to 0.10 per cent, 0.12 to 0.15 per cent and 0.069 per cent phosphorus, respectively.[2] Some samples contain as high as 57.48 per cent manganese.[3] In the State of Bahia mining has been carried on in one district about 30 miles southwest of the port of Bahia, where there are estimated to be 700,000 tons of psilomelanic ore. The ore which has been mined averaged 43 to 49 per cent manganese, 3 to 6 per cent iron and 0.016 per cent phosphorus.[4] It ranges in size from small lumps to masses weighing as much as 1½ tons. In the State of Matto Grosso the two deposits that have been worked are a few miles south of the river port of Corumbá, to which river vessels ply from Buenos Aires. Some of the ore has as much as 60 per cent manganese, but the average is about 46 or 47 per cent, with 9 to 10 per cent iron. The deposits are in the hands of an English-American company which has a 70-year concession covering about 25,000 acres. There are reported to be many other deposits in these three states, as well as the others mentioned above, some of which are most promising.

Before the war the price per unit of manganese was about 14 cents, or $6.70 per ton, less moisture. There is an export tax of 10 per cent in Minas Geraes, based on the official valuation, which varies so much that in one year the amount of the tax per metric ton ranged from $1.80 to $3. The reserve of Brazil's manganese deposits is said to be sufficient to supply the United States with all its requirements almost indefinitely.

Other War-Time Sources of Supply

Ecuador has been working some manganese deposits near Quito for export, but the only other country of South America besides Brazil that has shipped manganese in any large quantities is Chile. Prior to 1905 that country had sent over half a million tons to the United States. About that time competition from Russia and India developed and stopped production in Chile and there has been little since. In the 3 years preceding 1921 shipments amounting to about 15,000 tons were made, but these were discontinued in 1921 because of the high ocean freight rates. With lower rates it is thought that manganese ore can be sent to the United States with good profit and that this can be further increased by improving methods of handling. The chief production has come from the Carrizal district in the Province of Atacama and the Corral Quemada district in Coquimbo, but there are many others that have been or might be worked. The ore formerly mined carried up to 52 per cent manganese.

Cuba, Costa Rica, Panama and Mexico also answered the war-time call for manganese. The largest Cuban deposits are in the eastern end of the island, in the Province of Oriente. There are smaller deposits in the provinces of Pinar del Rio and Santa Clara. In Costa Rica manganese mining and exporting were started in 1916, when 1,305 tons was shipped. In the next year exports rose to 8,191 tons, and in 1918 to 9,893 tons. In 1919 they fell to 7,852 tons. In Panama seven manganese deposits were profitably working during the war, the bed lying near the historic port of Nombre de Dio, on the Atlantic side of the country. These were old workings that had been closed down since the beginning of the century and were reopened only in 1916. Other deposits, near Porto Bello, are said to be ex-

tensive. The Mexican mines are found in Chihuahua, Puebla, Chiapas and Lower California, the manganese being often associated with gold, silver or iron. Production in 1917 amounted to 73 metric tons, in 1918 to 2,878 tons, in 1919 to 2,294 tons, and in 1920, according to preliminary figures, to 838 tons. The ore shipped to the United States has averaged 40 to 48 per cent manganese. Besides these countries, Uruguay has pockets and traces in all parts of the country, two or three of which are worked for local purposes, and one company in Argentina has offered to supply 200 tons of ore a month for export from that country, provided a market can be found.

Chromium Found in Brazil, Cuba, Guatemala and Mexico

In chromium production four countries are listed, although production in none of them has reached large proportions. These countries are Brazil, Cuba, Guatemala and Mexico, in each of which the deposits were opened up by the war demand. Brazil took the lead in exports, and in 1918 shipped 17,854 tons. This fell off in 1919 to 4,800 tons and in 1920 to 3,451 tons; the average value in the last year was $21.36 per ton. The Brazilian ore came from a single district, near Queimadas and Bom Fin, in the State of Bahia, but there are other deposits reported farther inland, near the São Francisco River. The ore shipped has run about 44 to 46 per cent chromic oxide. The producing deposit is owned and operated by Americans. In no other South American country have deposits of any importance been uncovered, although in Venezuela, on the Coro Peninsula, and in Colombia, near Antioquia, occurrences of the ore have been reported, and a blast furnace near Medellin, in the latter country, is said to have produced chromiferous pig iron.

The Cuban deposits have been surveyed, and since 1916 several thousand tons has been exported to the

FIG. 14—SOUTHEAST END OF THE MAIN WORKINGS AT THE TOP OF THE MORRO DA MINA MANGANESE MINE, THE LARGEST IN BRAZIL

United States. The figures are as follows: 1916, 35 tons; 1917, 17 tons; 1918, 8,963 tons; 1919, 14,693 tons; 1920, 710 tons; 1921, 600 tons.[5] The deposits are found in twelve groups, all within 25 miles and most of them within 10 miles of the north coast, beginning with the Province of Havana and extending to the eastern end of the island. The eastern part of Havana has one deposit and the Province of Matanzas has two. The most important sources are found in the Province of Oriente, south of Nipe Bay, near the Mayari iron mines of the Bethlehem Steel Co., which has been taking out the chromite. About 40,000 tons of ore is now in sight. Next in importance are the Cayoguan and Potosi deposits, where it is estimated that there is an apparent reserve of about 35,000 tons. These lie near the eastern end of the island northeast of Baracoa, and are owned by two groups of American interests. Deposits near the town of Camaguey are said to have reserves of 20,000 tons. Of prime importance also are the chromiferous iron ores of Cuba found along the northeastern coast. Although present

FIG. 15—SHARP CONTACT BETWEEN MANGANESE ORE AND ROCK IN MORRO DA MINA

Black line at left shows contact, the lightest material is rock, the remainder is ore.

in vast amounts, these ores have so far been mined only at Mayari.

The changed conditions brought about by the war caused the development of chromite deposits in Guatemala in 1917, in which year 182 tons was sent to the United States. This increased in the three following years to 1,212 tons, 1,686 tons and 1,122 tons, respectively. The ore is described as very pure, averaging about 58 per cent chromic oxide, and is especially valuable for chemical purposes. It is in serpentine and is found about 100 miles inland from Puerto Barrios. Nicaragua is also said to have deposits of unknown extent, from which small shipments have been made. A part of Mexico's production of chromite is of high grade, containing as much as 54 per cent chromic oxide. This occurs in the Department of Progreso, from which shipments have been made to the United States. Other deposits, also worked during the war, are found in the Department of Jalapa.

Tungsten Resources of South and Central America

Bolivia, Peru and Argentina are the South American producers of tungsten, the first named being the most important. The production of Bolivia in recent years, in concentrates of 60 per cent tungsten, has been as follows: 1913, 278 long tons; 1914, 272 tons; 1915, 780 tons; 1916, 2,987 tons; 1917, 3,827 tons; 1918, 3,363 tons; 1919, 1,963 tons. Four districts lead in tungsten production—viz., those around La Paz, Oruro, Potosi and Cochabamba—although the deposits are not confined to these regions. The mines are in or on the sides of the eastern Cordilleras, extending over about

[5] U. S. Import figures.

400 miles of territory, from Puerta Acosta to Chorolque. The principal mines of the La Paz district are the fields of Palca or Yungas, and Quime or Inquisivi, with others of importance at Araca and Colquiri. In the Oruro district there are some important scheelite deposits at Conde Auque and elsewhere, and the Uyuni district has produced, according to report, some hübnerite of remarkable purity at Salasala and in other localities. Wolframite is obtained from a great number of mines. The deposits are generally in veins and are closely associated with tin, although many tungsten deposits contain little or no tin. The average cost of mining seems to be about $12 a ton at the mine.

Production in Peru, amounting to 200 to 500 tons annually, is practically confined to the districts of Conchucos and Corogno, both near the ports of Salaverry and Chimbote. Deposits are reported to be large but of low grade, and their working fluctuates sensitively with prices for the ore in Liverpool and New York. Production is almost entirely in the hands of Indians, and is carried on in a very primitive manner. Before the war German interests were a controlling element in tungsten mining.

The Argentine ores occur in the pampa range of mountains, an isolated range lying about 20 miles east of the Andes. The deposits are more abundant in San Luis and Cordoba, but also occur in La Rioja. The ores are found at an elevation of 2,000 to 5,000 ft. They consist of wolframite, hübnerite and scheelite, and are associated with ores of bismuth, tin, mica, copper and molybdenum. The veins contain ½ to 1½ per cent tungsten in unevenly distributed crystals, lumps and slabs, weighing up to 110 lb. Mining is of the crudest sort, and the deposits are seldom worked to any exact depth. Exports in recent years have ranged from 175 to 1,000 tons. A sample of the ore from Catamarca, sent to the United States, was found by the Bureau of Mines to contain about 80 per cent scheelite and 11 per cent silica. Mexico has deposits of tungsten ore,

FIG. 16—NATIVE CHOLO INDIAN CARRYING ORE FROM AN OLD SPANISH MINE

The method of handling is so crude that only about 60 per cent of the ore is saved.

FIG. 17—OPEN CUT WORKING IN MANGANESE MINE

The dark portion at left is ore, the lighter material is rock.

which are apparently a continuation of those of southern Arizona. The known deposits apparently all carry scheelite, which is associated with copper minerals. The Mexican output is given as 187 metric tons of tungsten (doubtless concentrated ore) in 1917, 149 tons in 1918, 22 tons in 1919 and 33 tons in 1920.

Two-Thirds of the World's Supply of Vanadium

Of two other important steel alloys, vanadium and molybdenum, one department of one country supplies a very large part of Latin America's whole contribution. This is the Department of Junin, in Peru, in which the well-known Cerro de Pasco copper mines are located. This department contains numerous deposits of asphaltite, running as much as 500 ft. in length and containing an average of 1 per cent vanadic oxide.

The one deposit, however, which has attracted commercial attention is very much richer in vanadium. It is known as the Minasragua deposit and consists of a lens-shaped bed of mixed hydrocarbon and vanadic sulphide 300 ft. long and with a maximum width yet to be determined but probably between 30 and 40 ft. During the last 15 years this single deposit has furnished from 60 to 85 per cent of the world's supply of vanadium. The bed was originally of interest to miners because of the coal, but the sulphur content was too high to permit profitable exploitation and it had been abandoned when the manager of a nearby smelter discovered, in 1905, that the deposit was rich in vanadium. It was at once denounced and was later sold to an American company, which in turn has recently disposed of it to a company allied with the Bethlehem Steel Co. Since 1907 the total ore produced has carried a content of more than 5,000 tons of pure vanadium. The ore is called "patronite," and analyses give about 20 per cent vanadium and 59 per cent sulphur. The exploiting interests have established a large reduction plant near the deposit in which the ore is calcined to a sulphur content of only about ½ per cent, the vanadic oxide content being raised to 40 or 50 per cent. The Bethlehem Steel Co. plans to increase this, by further treatment, to 85 or 90 per cent before shipping.

The Arqueros silver mines in the Department of

La Serena, Coquimbo Province, Chile, are said to contain lead and copper vanadates, and in the State of Chihuahua, Mexico, the lead ores have been found to contain vanadium. The mineral is also reported from Zacatecas, Guanajuato, San Luis Potosi and Hidalgo, in Mexico. The asphalt of Mendoza and Neuquen, in Argentina, has a high vanadium content. When analyzed the ash has been found to consist almost entirely of vanadium salts, constituting 0.3 to 0.6 per cent of the whole. The Peruvian deposits, however, are the only ones in the world, aside from those in the United States, that are worked commercially.

Molybdenum and Cobalt

Peruvian production of molybdenum is not large, the total to date amounting to only a few tons. The producing deposits are in Juaja Province of the Department of Junín, but others are found in the Departments of Cuzco, Ancachs and Huanuco. The ore averages 5 per cent molybdenite, this being concentrated to 80 per cent for shipment. Molybdenum ores are known in the Mexican states of Sonora, Sinaloa, Oaxaca, Hidalgo and Jalisco, but only in the first named have they been developed to any extent. In the Sahuaripa district pockets of the pure mineral are found, and molybdenite, molybdite and wulfenite are found in lead and copper ores of other districts. In 1918 27 metric tons of ore was produced, in 1919 about 1.7 tons, and in 1920 about 0.6 ton. Bolivia has produced a few tons of

FIG. 18—OLD METHOD OF ORE CRUSHING IS STILL USED FOR TEST SAMPLES. POTOSI, BOLIVIA

molybdenum ore, the mineral being obtained from the Illampu range.

Cobalt is found in two South American countries, but production is spasmodic and of no great importance. In the Chilean Province of Atacama veins of cobalt oxide, arsenate and sulpho-arsenide, in which the ore averages 4 per cent cobalt, have been worked, the chief mines being about 30 miles from the port of Huasco. Rich veins of cobalt ore are found in the silver mines of this province, as well as in Coquimbo and Santiago. In Argentina cobalt ores have been reported from La Rioja and Catamarca.

Titanium and zirconium are found in limited quantities, the former in various parts of Latin America, usually associated with iron ores, and the latter in Brazil. The iron ores of São Paulo, Brazil, are said to be high in titanium and the diamond-bearing sands of Bahia and the monazite sands of the seacoast contain considerable amounts of both rutile and ilmenite. The zirconium of Brazil occurs in two forms, as a free zirconium oxide associated with silica, called baddeleyite or brazilite, and as an oxide combined with silica, known as zircon. The former carries 80 to 85 per cent ZrO_2 and the latter about 65 per cent. The chief deposits are in a mountainous region about 130 miles north of the city of São Paulo. They have not yet been fully explored, but appear to be very extensive. The average zirconium content of the ore which comes from Brazil is about 78 per cent.

Part III, which will discuss the Latin-American resources of the platinum metals, lead, zinc, antimony, bismuth, mercury, mica, monazite, asphalt, graphite, borax, potash and other minor minerals, will appear in a subsequent issue.

Byproduct Coke Operations for 1920

Figures have just been announced by the U. S. Geological Survey showing by states and by classes of coke the production, sales and use at producers' plants of byproduct coke made during 1920.

Of the total coke production, which was about 33 million tons, 26 per cent was sold by the producer and the remainder was used in the producers' plants. This indicates how largely the byproduct coke business is connected directly with the metallurgical industries. Of the sales about half, or 12 per cent of the total coke, was marketed as furnace size; 5 per cent of the total coke was marketed for foundry use, and 7 per cent was marketed for domestic and other similar fuel uses. Of the 7 per cent of the total coke which appeared as breeze or screenings, 2 per cent was sold and 5 per cent was used by the producer.

Reports to the Geological Survey indicate that the value per ton of the coke sold was approximately as follows: Furnace size, $10.57; foundry size, $13.86; domestic, $8.92; breeze, $2.22.

The steady increase in the ratio of byproduct coke plants to beehive ovens is reflected in the figures compiled on the byproducts obtained from coke-oven operations in the same year, shown in the following table:

BYPRODUCTS OBTAINED FROM COKE-OVEN OPERATIONS IN 1920 AND 1921

		1920		1921
Product	Unit	Production	Quantity	Estimated Production (*a*)
Tar	Gallons	360,664,124	174,363,696	233,000,000
Ammonia:				
Sulphate	Pounds	675,816,486	626,013,975	.....
Anhydrous or free ammonia (*b*)	Pounds	65,777,259	62,076,772	.....
Sulphate equivalent	Pounds	(938,925,522)	(874,321,063)	607,000,000
Gas:				
Distributed through city mains	1000 cu.ft.		53,220,824	
Used in steel or affiliated plant	1000 cu.ft.	476,485,744	151,764,807	308,000,000
Used under boilers etc.	1000 cu.ft.		25,430,288	
Light oil and derivatives:				
Crude light oil (*c*)	Gallons	109,709,915	1,067,045	71,000,000
Benzene: Crude	Gallons	8,747,572	1,510,420	.....
Refined	Gallons	16,977,556	15,720,356	.....
Motor fuel (*d*)	Gallons	57,645,462	55,764,265	.....
Toluene: Crude	Gallons	287,142	.....	.....
Refined	Gallons	2,710,649	2,470,364	.....
Solvent naphtha	Gallons	5,678,525	4,695,464	.....
Naphthalene: Crude	Pounds	11,246,807	11,507,703	.....
Refined	Pounds	2,921,282	2,941,059	.....

(*a*) Estimated by assuming that the quantity of the several byproducts obtained bore the same relation to the known production of coke in 1921 as in 1920. The recoveries per ton of coal charged in 1920 were as follows: Ammonia (sulphate or equivalent), 21.4 lb.; tar, 8.2 gal.; crude light oil, 2.7 gal.; gas, 10.8 M cu.ft. (*b*) Mostly ammoniacal liquor, reported in content of NH_3. (*c*) The quantity of crude light oil refined by the producer amounted to 106,564,417 gal. (*d*) The benzene content of motor fuel ranged from 50 to 100 per cent.

Recovering Coal and Coke From Ashes

By William D. Green

MACROSCOPIC examination of the ashes discharged from certain industrial plants reveals the fact that these ashes or cinders contain a large amount of unburned coal as such together with a large percentage of coke.

A representative sample from a cinder pit containing several hundred tons showed by analysis that the ashes contained 57.8 per cent combustible matter and 42.2 per cent ash. The average analysis of the coal from which these cinders resulted is:

	Per Cent		Per Cent
Moisture	2.03	Ash	10.03
Volatile matter	44.00		
Fixed carbon	43.94	Total	100.00
		Sulphur	0.56

The purpose of the work described in this paper is to show that the recovery of the unburned portion of these cinders is possible, and that the product recovered constitutes a valuable fuel.

First Test

A sample of cinders from one of the factories of the Utah-Idaho Sugar Co. was ground to pass a 10-mesh Tyler standard screen having an opening of 1.651 mm. The sample was then treated by flotation in a Janney test machine using a mixture of raw pine oil and Barrett No. 4 flotation oil.

The results of Test 1 given in the accompanying table indicate a fair recovery of the combustible matter—viz., 70.6 per cent—and a satisfactory removal of the refuse—viz., 83.7 per cent. Out of every 100 tons of cinders there would be obtained 47 tons of recovered coal having an ash content of 15.2 per cent and a combustible content of 84.8 per cent.

Second Test

Another portion of the same cinder sample ground as above was treated by flotation in a Janney test machine using a mixture of Barrett No. 4 flotation oil and crude turpentine. Toward the last of the test a small quantity of sulphuric acid was added in order to make a cleaner froth.

The results of Test 2 show a better recovery of the combustible matter—viz., 88.7 per cent. The removal of the refuse is very satisfactory, since the recovery of the combustible matter shows an increase over that of Test 1 amounting to 18.1 per cent.

The tests show that the carbonaceous matter can be removed from cinders with a satisfactory recovery.

RESULTS OF TESTS

	Per Cent By Weight	Analysis—Ash, Per Cent	Analysis—Combustible, Per Cent	Distribution of Original—Ash, Per Cent	Distribution of Original—Combustible, Per Cent
Test 1:					
Original cinders	100	42.2	57.8	100	100
Recovered coal	47	15.2	84.8	16.3	70.6
Refuse removed	53	68.7	31.3	83.7	29.4
Test 2:					
Original cinders	100	42.2	57.8	100	100
Recovered coal	61	16.0	84.0	22.8	88.7
Refuse removed	39	83.2	16.8	77.2	11.3
Test 3:					
Original cinders	100	42.2	57.8	100	100
Recovered coal	61.4	12.9	87.1	18.8	94.5
Refuse removed	37.3	91.6	8.4	81.2	5.5

The small quantity of acid used helped materially both the floating qualities of the coal as well as assisting in the dropping of the refuse. Knowing that the use of acid would be prohibitive in commercial work, it was decided to grind finer before going to flotation.

Third Test

A third portion of the same cinder sample was ground in a ball mill to pass a 20-mesh Tyler standard screen having an opening of 0.833 mm. The sample was then treated by flotation in a Janney test machine using Barrett Salt Lake City heavy oil and after agitating for a few minutes adding a little crude turpentine. The Barrett oil did not produce much froth, but immediately upon adding the crude turpentine a voluminous clean froth formed.

A marked improvement over the other tests is shown in the results of Test 3. Undoubtedly in the coarser material much refuse was held mechanically in the pores of the coke, causing a high ash content. Out of every 100 tons of cinders there would be obtained 61.4 tons of recovered coal having an ash content of 12.9 per cent and a combustible content of 87.1 per cent, the latter being 94.5 per cent of the combustible matter contained in the original cinders.

The recovered coal can be burned as a powdered fuel, mixed with slack or mine run, or briquets.

Midvale, Utah.

Manufacture of Steel Gages

A SECOND meeting[1] of manufacturers and users interested in permanent gages developed the fact that satisfactory results could most probably be had with the proper one of the following steels:

1. Carbon steels; (*a*) 0.85 C, (*b*) 1.10 to 1.20 C, with or without 0.5 Cr.
2. Ball-bearing steel; 1.10 C, 1.40 Cr.
3. Non-deforming steel; 0.90 C, 1.25 Mn, 0.5 Cr, 0.5 W.
4. Case-hardening steel (chromium-nickel).

One manufacturer uses ball-bearing steel for plug gages. In his experience they are free from soft spots, wear very well, and will stand more abuse than carbonized surfaces. Thread gages were made of low-carbon steel, carbonized and heat-treated. Thread gages are more carefully used, because it is evident that they will not stand abuse. After the usual quenching and drawing operations, the gages are rough ground to aid in relief of internal strains. Then the gage is reheated to 20 deg. under the original draw, and slowly cooled. High-class work is drawn a third time, in an effort to completely "season" the piece against subsequent dimension changes.

Another manufacturer uses ordinary machinery steel for thread gages and miscellaneous gages and parts: C 0.20 to 0.30, Mn 0.90 to 1.10, Si below 0.20, P 0.06 to 0.08, S 0.06 to 0.08. Plain plugs and ring gages are made of 1.00 to 1.10 carbon steel. Blanks are normalized after rough forming by heating to 1,475 deg. F. and cooling in oil. Plugs up to $\frac{5}{8}$ in. are carburized in cyanide at 1,425 deg. F., for 10 to 20 minutes, depending upon the size, cooled in air, reheated in cyanide to 1,420 deg. C. and quenched in soluble oil. Larger plugs and rings are carburized in 1 part new charred bone and 2 parts used bone at 1,425 deg. F. for 2 to 5 hours, depend-

[1] See "Permanence of Steel Gages," Chem. & Met. Eng., vol. 26, p. 248 (Feb. 8, 1922).

ing on size, and quenched in oil. Seasoning consists of ten alternate dips in boiling and cold water, each immersion bringing the entire mass to temperature. The chief difficulties experienced in this program is that ring thread gages will change in size excessively, some expanding and others contracting, a difficulty probably due to non-uniform steel rather than heat-treatment.

Thread gages for artillery ammunition ordinarily give a life of about 6,000 tests. Recently some gages which are still good after 50,000 tests were made by the Cleveland Twist Drill Co. of stock steel of the following composition:

Carbon	0.99	Silicon	0.24
Manganese	0.35	Sulphur	0.026
Phosphorus	0.012	Chromium	1.47

These gages were rough machined and annealed at 1,425 deg. F., taking 3 hours to bring the steel up to the heat and holding it there for 7 hours. They were then cooled slowly, after which the gages were finished, then hardened at 1,500 deg. F., quenched in oil and drawn to 350 deg. F.

They were heat-treated to produce a fine structure in the annealed condition. They machined easily, hardened uniformly without appreciable distortion and when finished had a smooth surface capable of resisting wear due to friction.

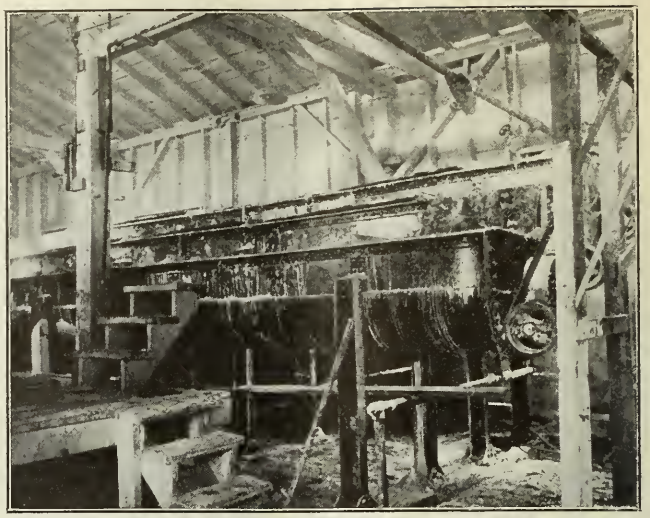
The analysis is close to that of the steel used in the races of the best ball bearings. It is not a high-priced steel, has a wide heat range, low risk in heat-treatment, changes but little in hardening or afterward, and the tools that are made from it are extremely tough. A thread gage made from this steel should cost less than one of machinery steel, pack-hardened, because the cost of pack-hardening would be more than the difference in the cost of the steel. Pack-hardening, if at all satisfactory, requires not less than 8 hours, while a gage made of the steel mentioned can be satisfactorily hardened in 10 minutes.

By accident, when these gages were made, the manufacturer left only 0.005 on pitch diameter for finish after hardening, but the gages cleaned up and took a very good finish. This shows conclusively that the steel used showed no appreciable change in hardening.

Improved Type of Continuous Crystallizer

Among the newer forms of chemical plant equipment designed for economy in operation is the Swenson-Walker continuous crystallizer shown in the illustration herewith. The internal moving parts of this device scrape across the internal semi-cylindrical surface of the troughs with such a small margin of clearance that caking on the surface is made impossible. The movement is sufficiently slow that the material which is crystallizing in suspension is not moved fast enough to produce much more than a minimum of fine material, while the shape of the flights is such as to produce a very slow, easy, forward movement of the entire mass of material at a rate just commensurate with the production wanted.

Tests carried out on the apparatus operating on the production of trisodium phosphate showed a weighed production of exactly 10,000 lb. in 12 hours, with an excess production in the form of crystals in process which were not present at the beginning of the 12-hour run. The effort was then made to test out the apparatus for continuity of operation and without any difficulty a run of approximately one week was carried through at or above the rated capacity of 10 tons per hour.



THE SWENSON-WALKER CONTINUOUS CRYSTALLIZER

The power consumed for the above-mentioned tonnage was only within the normal load of a 2-hp. motor. The water consumption for cooling was less than 5 gal. per minute, due to the fact that the entire apparatus is set up to run on the principles of a counter-current heat exchanger, and where it is possible to arrange the heat balance of a chemical plant properly, there is actually a very small amount of heat lost when using this system. This is particularly true due to the fact that the flow of cooling water, as well as the production of crystals, is continuous.

The question is often asked with reference to crystallizing problems whether a larger crystal can be obtained. The answer to this depends on the comparison which is made, but in the present instance it was found that instead of the previous figure of 65 per cent of the crystals being held over a screen of a certain size, the uniformity with which the crystals were produced raised this figure to 85 per cent. In other words, the dry fines produced in the plant were not over 45 per cent of the previous production, the fine material in this case, as in a great many others, being of far less market value.

The entire crystallization process need occupy only a part of the time of one man.

Recent Work on Reclamation of Molding Sand

The American Steel Foundries Co. has permitted a representative of the Molding Sand Research Committee to make a digest of the sand reclamation work carried on by its engineering staff.

After experimenting on different lines and thoroughly going over methods employed in other plants, a process of reclaiming old sand called "centrifugal scrubbing" was developed.

After establishing the principle of this method, equipment was designed which permits a recovery of about 70 per cent of refuse sand. Cost figures for 1921 show that a ton of reclaimed sand costs about $1 against the cost of new sand at the plant of $2.65 to $3.85 a ton. The process involves cleaning the sand grains of adhering fused material, then separating by air currents the good sand from the bad material.

The report covers the theory of sand reclaiming, centrifugal air-scrubbing process, cost of reclaiming sand by the latter process, and a description of the proposed sand-reclaiming unit.

Static Electrical Charges Detected by Neon Tester

By B. E. Shackelford, Ph.D.
Physicist, Westinghouse Lamp Co.

NEON, one of the rare gases of the atmosphere, has recently been made to serve as the basis of a convenient indicating device for the testing of high-tension electrical circuits. It now appears that this device, which was originally developed as an ignition gage for gas engines, may have a wide variety of uses in fields far removed from that of the automobile. The neon tube is especially sensitive to static electricty, and it may prove of great utility in detecting such charges in chemical plants and other factories where static electricity is regarded as a dangerous source of trouble.

During the last few years there have been many instances[1] of fires and explosions in mills, elevators and chemical factories caused by the discharge of static electricity which had gradually accumulated in the presence of flammable dust or vapors. Recently there was described in the columns of this magazine an explosion[2] of an agitator which was being filled with naphtha. Apparently this explosion was caused by the fact that the naphtha had become charged with static electricity while being pumped through pipe lines. The recent investigations of the Bureau of Chemistry and of the U. S. Grain Corporation have shown that one of the major fire and explosion hazards around grain elevators, flour mills, aluminum-powder factories, rubber plants, etc., is the accumulation of static electricity. It is, of course, always intended that such static charges be drained off by ground wires, but it is a fact that this desired end is not always attained. Pulleys, belts, grinding equipment, revolving reels and similar types of equipment are the most likely sources, and attention is usually given to their proper grounding. Sometimes, however, static accumulates in places where it is unsuspected and at other times it is found in places which are difficult to ground.

Description of the Neon Detector

The type of detector developed by the Westinghouse Lamp Co. and marketed under the trade name "Spark C," is an adaptation of the familiar Geissler tube. It is well known that the discharge of electricity through any such tube yields a glow, the color of which depends primarily on the gas contained in the tube. Pure neon is used in this instance both because of the ease with which it passes an electrical discharge and also because of the resultant color, a bright orange red. Even in daylight and with only a very small current passing, the resulting neon glow is quite marked.

The neon-filled Geissler tube is suitably mounted in an insulating casing of convenient size and provided at one end with a small metal contact tip and at the other end with a small condenser plate. The capacity of this plate to ground is sufficient for the current necessary for operation so that when the tester is brought near a live high-tension line or is touched to a body statically charged, the characteristic neon glow becomes visible.

The neon tube of the standard device operates at any voltage above 350 volts, but in the mounting one lead is connected only to the condenser and this increases the voltage requirement somewhat so that the complete device begins to glow at about 700 volts of any ordinary frequency. Certain factors of design also affect the operating voltage to a certain extent.

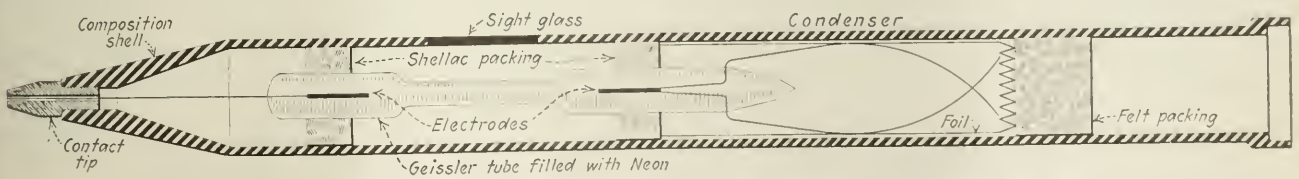
Static charges, although they may contain comparatively little energy, have usually a very high voltage to ground and consequently give a brilliant glow in the tube. It should be noted that the glow is exhibited each time a current passes; with rapidly alternating current there is an apparently continuous flash. In the case of static there is a glow when the discharge passes through the tube to the condenser and another glow when the condenser is discharged by touching the point to the hand or to any other ground.

An indication of the sensitiveness of this device may be obtained by walking across a rug and touching the tip to a radiator, metal desk or other grounding device. The tester may also be made to glow by rubbing it with a piece of wool or, on particularly dry days, even by bringing it near the body. At other times a greater frequency of glow may be obtained by simply moving it near to and away from some portion of one's own clothing; a discharge will be noticed as the tester passes over particularly localized charges on the material. This great sensitivity is very useful in detecting static, and accordingly the field of application is quite extended.

Its Uses in Chemical Plants

It is possible for a most inexperienced workman to use this neon device to test out each portion of the equipment in a chemical-manufacturing plant as well as all parts of the conveyor systems, grinding and milling machinery, etc. It is usually found that although a system may apparently be well grounded, there are a number of places where there is a sufficient static charge to give an indication with the tester. The inspector, having it with him on his inspection trips, can immediately locate the sources of possible trouble and see that they are eliminated.

In certain cases it is advantageous to drain off the static through the tester itself, connected directly to the ground wire. As soon as sufficient charge has accumulated to raise the voltage to approximately 350 volts, the tube flashes and calls attention to the presence of trouble. In this way there is available at all times an indicator of the rapid development of charges which otherwise might not be detected as soon as desirable.



A SECTIONAL VIEW SHOWING CONSTRUCTION DETAILS OF NEON TESTER

Synopsis of Recent Chemical & Metallurgical Literature

The Oxidation of Ammonia.—The *Journal of the Society of Chemical Industry* (vol. 41, No. 4, p. 37T, of Feb. 28, 1922) contained a report of recent work conducted by the United Alkali Co. on the catalytic oxidation of ammonia for supplying oxides of nitrogen to its chamber sulphuric acid plants and in the production of nitric acid. The former application has been so successful that it is now installed at all the chamber plants of the company. The latter is not being used at present because of the prohibitive cost of concentration of the weak nitric acid produced.

The converter used in connection with the acid plant at Widnes, which has a capacity of 250 tons of O.V. per week, was made of aluminum and consisted of a square base with two inlets and a tapering hood connected with an aluminum bend. An electrically heated gauze was used at first, but was soon replaced by an unheated fourfold gauze. It was also found that aluminum was not suitable for the construction of the converters, as its melting point is dangerously near the proper conversion temperature. Cast iron seemed satisfactory for the hood except for the risk of rust particles dropping on the gauze. Enameled iron was found to be entirely satisfactory and later it was found that iron could be satisfactorily and cheaply protected by painting while hot with Seller's cement, a mixture of sodium silicate solution and barium sulphate. The gauze was 6 x 4 in. cross-section, each gauze being woven of platinum wire 0.065 mm. thick, 80 mesh to the inch, the four pieces being stitched together with platinum wire. The gauze is carefully cleaned before fixing in the converter by boiling in hydrochloric acid and washing with distilled water.

With a plant of this type, with no preheating of the gas, conversions by analysis of 86 to 89 per cent were obtained. The capacity of this unit was limited to about 25 lb. of sodium nitrate per sq.in. of platinum per day. Any attempt to increase the speed of the gas beyond this limit led to a falling off in efficiency and the appearance of ammonium nitrate and nitrite in the condensite. In an attempt to improve this yield a preheater was designed to utilize the heat in the exit gases for preheating the gas. It has an internal diameter of 12 in. across the tube plates, with 7 tubes each 2¾ in. mean diameter and 2 ft. long. The tubes are either enameled or painted with Seller's cement. The inlet gas temperature is raised to about 300 deg. C. in the heat interchanger and the yield of the unit is increased to about 93 per cent as shown by the gas test.

It is reported that one platinum gauze was used continuously for 18 months before failure occurred at the point where it is held in the frames; another was used for 16 months before it was accidentally broken by a fitter, and others have worked for over a year and are apparently in good condition. The loss of platinum varies from 0.002 to 0.04 oz. troy per ton of 100 per cent nitric acid produced. In addition to this, allowance must be made for the depreciation of platinum, owing to the difference in the price between new platinum and scrap. With new platinum at £22 10s. per oz. troy and scrap at £19 10s., a fair allowance per ton of equivalent sodium nitrate for chamber working is 9d. for depreciation and 9d. for platinum loss, or a total of 1s. 6d. per ton.

The quality of ammonia used throughout has been commercially pure 25 per cent liquor from coke ovens or gas works, free from sulphides. It is stated that more risk of danger to the platinum exists from traces of iron rust than from any impurities normally to be expected in the ammonia.

The plant for the manufacture of nitric acid consisted of a converter with 6 x 4 in. gauzes, identical with those described above, coupled up with a set of towers belonging to an ordinary nitric acid unit. The absorption system consisted of three earthenware towers 3 ft. in diameter and 16 ft. 3 in. high, packed with rings and balls, followed by two smaller towers 2 ft. by 11 ft. high, packed in the same manner. Water or weak acid was circulated over the first three towers by means of air lifts, while a solution of soda ash or caustic liquor was circulated over the last pair of towers. Additional secondary air beyond that introduced by the air lifts could be introduced into the first tower if desired. The gases were cooled before entering the first tower by passing through a gallery of silica pipes. The total condensing space in the unit was 417 cu.ft., but an additional tower was later added at the front of the system to give increased oxidizing space, and this increased the total tower space to 533 cu.ft. Without a heat interchanger this plant produced the equivalent of about 1 ton of 100 per cent nitric acid per week, the acid being actually obtained at about 50 per cent HNO_3 with an overall yield of 78 to 79 per cent, of which 5 to 6 per cent was in the form of sodium nitrate from the final scrubbing towers. After the introduction of the heat interchanger, the output of the plant increased to the equivalent of about 1¾ tons of 100 per cent nitric acid per week with a yield of over 84 per cent. The acid was concentrated in the usual concentrating tower, using sulphuric acid as a dehydrating agent.

Sulphur and Oxides in Ordnance Steel.—W. J. Priestley, steel superintendent of the U. S. Naval Ordnance Plant, read a paper on this subject before the February meeting of the American Institute of Mining and Metallurgical Engineers. He noted that steels having high transverse ductility have not been made successfully in the basic open hearth, despite that furnace's ability to reduce phosphorus; consequently it has been usual to specify the acid process, although it requires low sulphur and phosphorus melting stock. The U. S. Naval Ordnance plant has been very successful in making steels by duplexing, as follows:

Pig and scrap (60:40 ratio) with 8 per cent limestone and

*These ingots were made by a private industrial plant during the war.

enough ore to lower the carbon to 0.25 is charged in a 75-ton basic open-hearth furnace. On tapping it contains C 0.23, P 0.007 and S 0.016; 2 lb. of 50 per cent ferrosilicon and 3 oz. aluminum per ton are added to prevent any oxides reacting with the carbon before the molten steel can be teemed into the two 40-ton electric furnaces. Here a new slag is made up of burned lime, fluorspar and coke, and adjusted from time to time; its total weight amounting to about 2,500 lb. The bath is held in a reducing atmosphere for 3 to 5 hours, and the finished steel contains C 0.32 to 0.40, P about 0.01 and S less than 0.01 per cent.

In the electric furnace, any oxides in the steel are rabbled to the top, and are reduced to metal by the carbon in the slag. When these reactions are complete, calcium carbide may form, which reacts with FeS or MnS, forming CaS, which is absorbed by the slag. It is important to remember, that deoxidation is preliminary to desulphurization, and it may be inferred that an electric heat which has markedly reduced sulphur has also produced a deoxidized metal.

Such steels appear to have a minimum number of slag inclusions, of one size and appearance—namely, minute round specks. High-grade acid open-hearth steel has, in addition, larger sheets or fibers of slag drawn out in forging. Basic steel includes both types of inclusions, but the elongated masses appear more brittle and badly shattered. Table I shows the excellent ductility in transverse specimens taken from large gun forgings made by the Naval Ordnance plant of duplex electric steel, as compared with acid open-hearth or basic electric furnaces from other sources, but possessing identical analysis except sulphur (and, inferentially, oxide).

The paper includes a very interesting discussion of the relative merits of electric and open-hearth steel, and detailed information on slag and metal analyses at various stages of the process.

Recent Chemical & Metallurgical Patents

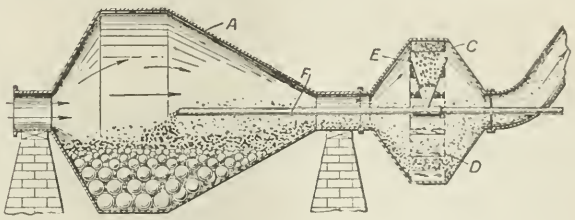
British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Tanning.—A process of tanning consists in treating the hide with an arsenic compound which, if insoluble in water, has been rendered soluble or colloidal. In one example, a tanning agent is prepared by adding to a suspension of an insoluble compound of arsenious, arsenic, sulpharsenious, sulpharsenic, phenylarsinic or diphenylarsinic acid or arsenophenol a sufficiently large proportion of an alkali salt to produce a colloidal solution. In another example, the hide is treated with a free organic sulphonic acid of a hydrocarbon or with a synthetic tanning agent obtained by condensation and suphonation of a phenol and hydrocarbon used as a solvent for an arsenic compound, particularly a heavy metal salt of arsenious or arsenic acid. (Br. Pat. 171,693; not yet accepted. Gerb- und Farbstoff-werke H. Renner & Co., Hamburg. Jan. 11, 1922.)

Synthetic Tanning Agents.—Tanning agents are obtained by sulphonating the resinous condensation products prepared from phenols and formaldehyde with the aid of basic condensing agents. Starch, sugar, glucose or materials containing them may be mixed with the parent materials or the resins before the sulphonation. The sulphonation may be carried out so as to yield either readily soluble products or products which are sparingly soluble or insoluble. The readily soluble products have the property of solubilizing the sparingly soluble products or the unsulphonated resins or the insoluble phlobaphenes contained in vegetable tanning agents, and the resulting colloidal solutions may be employed as tanning agents. The process may be carried out by sulphonating one portion of resin to give an easily soluble product, sulphonating another portion to give a sparingly soluble or insoluble product, and mixing the two; or the process may be conducted so as to give first an insoluble product and solubilize this by further sulphonation; or an easily soluble sulphonation product may be mixed with the resin and the mixture sulphonated; or the resin may be sulphonated under such mild conditions that only a portion is sulphonated. The alkali salts of the sparingly soluble sulphonic acids dissolve the insoluble sulphonation products, and the resulting colloidal solutions may be used for tanning. In making the parent resins, the crude reaction product resulting from the alkali fusion of a sulphonated hydrocarbon may be used; ammonia of an ammonium salt, such as the sulphate, may be added to the alkali fusion to give ammonia for the condensation. Any of the tanning agents described above may be improved by oxidation—e.g., by means of atmospheric oxygen, ozone, hydrogen peroxide, potassium bichromate, permanganate, perchlorate, perborate or persulphate, chlorine or nitric acid, or by electrolytic oxidation. According to examples, phenol is heated with formaldehyde solution and aqueous ammonia, aniline, caustic soda or sodium carbonate, the resulting resin is sulphonated by concentrated or fuming sulphuric acid, the product diluted with water and free sulphuric acid neutralized by alkali; crude cresol or α- or β-naphthol may be substituted for the phenol; starch, molasses or concentrated or dry sulphite cellulose lye may be added to the above initial materials before condensation and sulphonation; mixtures are prepared from an easily soluble and an insoluble sulphonic acid, an easily soluble sulphonic acid and a non-sulphonated resin, an alkali salt of an insoluble sulphonic acid and the free sulphonic acid, an easily soluble sulphonic acid and quebracho extract; examples are also given of the use of alkali melts of resorcin and naphthols. (Br. Pat. 171,729. Gerb- und Farbstoff-werke H. Renner & Co., Hamburg. Jan. 11, 1922.)

Classifying Ground Material.—The patent describes an apparatus for treating ground materials, pulps or slimes for the separation of the fine material from the oversize and comprises a rotary vessel *C* fitted internally with scoops *D* which pick up the larger particles from the bottom of the vessel and pass them into a hopper *E* leading into a pipe *F* from which they are discharged by means of



a current of liquid or gas or both. The apparatus is preferably combined with a grinding-mill *A* to which the oversize is returned by the pipe *F*, while the fine material is discharged from the vessel *C* with or without the aid of a current of air; or, in the case of a mill for wet grinding, the fine material is allowed to overflow with water from the outlet of the vessel *C*. (Br. Pat. 172,525. H. W. Hardinge, London. Feb. 1, 1922.)

Nitric Acid.—In the preparation of nitric acid from the gases obtained by the oxidation of ammonia, a portion of the gases is absorbed in towers in water or dilute nitric acid and the remainder is liquefied by refrigeration. After a preliminary cooling, during which no condensation occurs, the gases from the furnace are passed through coils or other acid-proof apparatus, cooled by means of cold water, to condense as much as possible of the water present and to give a dilute solution of nitric acid. The uncondensed gases then enter towers fed with water or the dilute acid obtained as above described by condensation. Before the unabsorbed gases are liquefied they are dried by treatment in one or more washing towers with liquid nitrogen peroxide, in the manner described in specification 164,734. The acid obtained by absorption of the nitrogen oxides in dilute nitric acid is treated finally with the liquid nitrogen oxides obtained by refrigeration of the unabsorbed gases. (Br. Pat. 172,979; not yet accepted. C. Rossi and C. Toniolo, Legnano, Italy. Feb. 8, 1922.)

Book Reviews

THE DISTRIBUTION OF GAS. By *Walter Hole.* Fourth edition, rewritten and greatly enlarged. London: Benn Brothers, Ltd. 700 pp., 749 illustrations. Price 50s. net.

This fourth edition of the standard work by Hole requires no introduction to American gas engineers. The author has apparently made a very thorough job of revision and has extended the work materially beyond the form in which the third edition appeared 8 years ago. Particular attention has been given in the new edition to the domestic use of gas and two entirely new chapters have been introduced, one on "The Industrial Uses of Gas" and the second on "Inferential Meters."

The volume represents an extended review of the standard English gas engineering practice. For the young gas engineer it is a most complete text book; for the experienced engineer it is a convenient reference volume for many details which cannot readily be borne in mind even by the most experienced operator. However, for an engineer in American gas practice the volume does not approach in value its undoubted merit for the English operator. Practice in the two countries is notably different in many respects and the usefulness of the volume in the United States is thereby seriously curtailed. It will, however, form a valuable reference book in the library of any gas engineering organization, as it is very suggestive of methods and equipment which must be considered in any new developments. However, for American operation it should not be trusted too fully in detail.

As in the earlier editions, the volume is addressed almost solely to those engaged in the production or distribution of public utility gas supplies. It will find little use in the library of the chemical engineer, as the methods and apparatus described are limited almost altogether to those involved in public utility practice. R. S. McBride.

ECONOMICS OF PETROLEUM. By *Joseph E. Pogue.* New York: John Wiley & Sons, Inc. 375 pp., 151 figures. Price $6.

"The purpose of this book is to present, in perspective, the more important economic facts relating to petroleum; to interpret the changes that are rapidly taking place in this field; and to project the trend of these changes into the immediate future." Thus the author states the object of this volume at the beginning of his preface. And rarely does one find an author who has so satisfactorily accomplished his purpose as has Pogue in the present work.

The author takes the industry from its broad economic foundations through to the intimate detail of the various special products from petroleum, and paints for the reader in true proportion a picture of the entire petroleum industry. Not alone does the picture include the business of the industry itself, but it also shows clearly the relation of the problems of petroleum production, transportation, refining and marketing to each of the important related industries which are users of petroleum products. This presentation of the industry and the related industries is done in a simple, clear way without that distortion or bias which has so commonly destroyed the principal value of otherwise worth-while contributions to the literature of the oil business. In this case the author brings a wide experience and intimate knowledge of the fundamentals of the business to his task without giving any evidence of partiality for producer, refiner or user, an accomplishment which makes his book a most valuable contribution to the subject.

Although written strictly from the standpoint of statistics and economics, the author does not allow these tools of industry to become an end in themselves. His analysis and graphical presentation of the important figures which are essential to an understanding of the business have been accomplished in a simple fashion but without sacrifice of accuracy. Thus the economics are given very practical value and the statistics made really useful in the service of industry.

The author is to be strongly commended for his use of large units in presenting the data instead of presenting nine or ten significant figures in most cases where it is well known that only three or at the most four figures really have any meaning. Thus in practically every case "the unit has been so chosen that the data could be expressed by three digits with a decimal point if necessary." The extensive use of graphical methods for presentation also is most satisfying. In this particular the volume is exceptionally useful to the reader who wishes to get quickly an approximate idea of trends in the industry. Moreover the graphical presentation in almost every case has been made without resort to complicated charts of obscure meaning.

The mechanical form of the book quite justifies the writer's expression of appreciation to those who have assisted in the mechanical preparation of the work. The author is particularly to be commended upon the use of running heads on the pages which mean something. Thus one can identify the major subject of a chapter by the heading of the left-hand pages and subdivision of the subject under discussion by the right-hand page heads. This is a very practical advantage, particularly in a volume such as this which discusses many detailed phases of a single broad subject.

The volume represents a most comprehensive consolidation in systematic form of the fragmentary information and data which have been scattered through much valuable literature of the past few years. It will now be available to a wide variety of readers in a convenient reference text. A great deal of the value of the book is the fact that it presents data from quite recent periods, in some cases extending well into or through 1921. Being to a large extent statistical in its nature, it is to be hoped that the author will find opportunity to prepare new editions at frequent intervals. If this is done, it seems certain that the work will become a standard text, not only with reference to the petroleum industry itself, but also in connection with the great problem which the author cites, "the coming necessity for increasing the over-all efficiency of petroleum—a problem that concerns not only the producers and refiners of oil but the manufacturers of appliances that consume its products as well."

The author might well have added at this point reference to those who use this fuel-burning equipment, for in many cases the user of petroleum products will find quite as much of value in this volume as will the producer. This is true of those in the natural gas, manufactured gas, automotive, oil-shale and many other related industries. The problems of each of these, in their relation to the petroleum business, is clearly set forth, and accurately interpreted in this work.

R. S. McBride.

AN INTRODUCTION TO THE ANALYTICAL CHEMISTRY OF THE RARER ELEMENTS. By *Louis J. Curtman, Ph.D.*, assistant professor of chemistry, chief of the division of qualitative analysis, College of the City of New York. 64 pp. New York, 1922. Published by the author. Price $1.25.

With the increasing industrial importance of the rarer elements has come a realization of the necessity for extending the usual courses in analytical chemistry so that the student may become familiar with the characteristic properties of this group of elements.

Dr. Curtman has prepared a sound foundation for this work by gathering together the characteristic tests for each of the rarer elements. All the reactions have been tried out carefully in the laboratory in order to eliminate those errors which somehow creep into the literature and are carried along with other data. The twenty-nine elements which are considered in detail are classified according to the usual analytical groups, but although some distinguishing tests are mentioned, no scheme for the separation of individual elements within a group has been included. It is to be hoped that Dr. Curtman will supplement this introductory text with one giving the analytical procedure for making such separations. Alan G. Wikoff.

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Senate's Draft of Permanent Tariff Changes Duties on Certain Chemicals

In the tariff bill, which the Finance Committee has just reported to the Senate, the dye and chemical embargo is to be extended for 1 year from the passage of the act.

Among the other changes made in the House bill are the following: The specific duties on acetic anhydride reduced from 8c. to 5c., boric acid reduced from 2c. to 1½c., citric acid increased from 12c. to 18c.

There were slight increases in the lactic acid rates. Arsenic acid was made dutiable at 3c. per lb.; white arsenic, 2c.; formic acid, 4c.; gallic acid, 8c.; red oil, 1½c.; oxalic acid, 4c.; phosphoric acid, 2c.; pyrogallic acid, 12c.; stearic acid, 1½c.

The specific duty on potassium aluminum sulphate was reduced to ¾c. a lb., but the ad valorem rate for all other aluminum compounds was increased from 25 to 35 per cent. Amyl, butyl and isopropyl alcohol were made dutiable at 3c. per lb. Fusel oil was reduced from 6c. to 2c. per lb.

The rates covering ethyl and methyl alcohol were reduced from 15c. to 10c. per gal. Ammonium nitrate was put on the free list. Oxide of antimony was made dutiable at 1½c. per lb. and 25 per cent ad valorem. Gum arabic was taken from the free list and made dutiable at ½c. per lb. Half a cent was added to the rate of barium chloride. Barium hydroxide was inserted in the bill with a rate of 1¾c. per lb. The barium nitrate rate was increased ½c. The rate on barytes is fixed at 1¼c. per lb. Bismuth compounds were increased from 25 per cent to 35 per cent ad valorem.

As had been previously announced, intermediate and finished coal-tar products were made dutiable at 50 per cent ad valorem and 7c. per lb. and 60 per cent ad valorem and 7c. per lb. The ad valorem rates were increased from 30 to 50 per cent and from 35 to 60 per cent respectively. The bill instructs the Secretary of the Treasury to prepare standards of strength for each dye.

Compounds of cellulose were added to the bill and made dutiable at 35 per cent ad valorem. Potassium and sodium cyanides are made dutiable at 10 per cent ad valorem. The ad valorem duty for formaldehyde was stricken out and specific duty of 2c. per lb. inserted. A rate of 8c. per lb. is provided for solid formaldehyde and 10c. per lb. for hexamethylenetetramine. The rate on refined glycerine is reduced from 3c. to 2c. per lb., bromine is dutiable at 5c. per lb. and bromine compounds at 8c.

Duties on oils are fixed as follows: Coconut oil, 4c.; cottonseed oil, 3c.; peanut oil, 4c.; soya bean, 3c., the latter to be admitted free if it is to be used in the manufacture of articles unfit for food. Copra, palm nuts, rapeseed and other oil-bearing seeds and nuts were added to the free list, as was nitrate of potash.

England Stands Firm on Dye Protection

A recent attempt to repeal the British dyestuffs protective legislation failed in the House of Commons by a fairly large majority. In moving the repeal of the legislation it was charged that British Dyestuffs, Ltd., had furnished only very inferior products at very high prices and that the consuming trades were being seriously hampered by lack of satisfactory colors. The government warmly defended both the company and the protective laws.

New Chemistry Building for University of Missouri

The University of Missouri, Columbia, Mo., has taken bids and will soon award a contract for the erection of a new chemistry building at the institution, to cost $125,000.

Action of Senate Finance Committee in Extending Embargo Has Encouraging Features

While the action of the Senate Finance Committee in deciding to recommend the extension of the embargo on certain dyes and chemicals for 1 year is a disappointment in view of the inadequacy of the time period, the significant feature of the committee's action is the acceptance of the embargo principle. Moreover, it is confidently expected that either the time period will be extended by action on the floor of the Senate or the President will be empowered to extend it if he should deem it necessary. The hope is expressed that the Finance Committee itself will include such a provision in its bill.

It is pointed out that the President has at hand the service of the entire administrative machine to determine whether or not the embargo should be extended. The feeling among chemical manufacturers is that any impartial and intelligent survey of the situation will develop the absolute proof that the embargo must continue if there is to be vigorous development of the new organic chemical industry. If such a provision is placed in the bill, it is believed that development will go forward with full confidence that the requisite protection will be forthcoming.

In that connection it is pointed out that provision must be made for the establishment of a well-equipped laboratory, manned by experienced chemists, to aid the dye and chemical division of the Treasury Department. The customs service must have this adjunct, it is declared, to enable it to guard against false concentrations, undervaluation and false labeling.

Another Week of Sideshows at the Dye Investigation

There is now no doubt in anyone's mind, even including Senator King's, that the stories of an American dye monopoly are fairy tales. The investigating committee is being treated to many sidelights and personal animosities which if one is detached from the industry may have a slightly humorous flavor. All of the old tariff fights are being reviewed and some new attitudes are occasionally developed. On the whole the conduct of the investigation leaves a good taste in one's mouth. It has progressed fairly rapidly and the conclusions are likely to be definite.

Exoneration of Dye Makers Expected

That the Shortridge committee will exonerate the manufacturers of dyestuffs of the charges which were made against them is evident. The record will be unique in Congressional annals, for never before have such sweeping charges been made against any group and been subsequently found to contain so little meat. It is really one of the best things that could have happened to the industry, for it shows it in an extremely favorable light. It has given the organic chemical manufacturers an opportunity to spread on record a full account of their history and their needs. Nothing could have been more salutary for the industry than the necessity of showing its inmost soul to the public and the legislature. Its needs now come into stronger light than they did in the Senate and House committee rooms. The veiled and open hints that there was a monopoly which were freely used at those times by opponents of the industry are completely and forever eliminated by this investigation.

Prominent Textile Man Testifies in Favor of Embargo

Henry B. Thompson, president of the U. S. Finishing Co. and also president of the American Association of

Finishers of Cotton Fabrics, chairman of the Dye Advisory Committee of the War Trade Board and member of the Dye Committee of the Textile Alliance, testified at some length last week. His company manufactures 300,000,000 yd. of cloth per year and operates plants in Connecticut and Rhode Island. He took occasion to deny the charges made by Senator King that he had in any way benefited by his membership on the dye committees. He further stated that Mr. Poucher of the du Pont Co. did not dominate the committees, an additional charge from Senator King. He then went on to analyze the opposition to the dye embargo. There are three main groups. The first consists of the manufacturers of textiles who are selfishly interested in obtaining lowest prices for dyes. The second group is small but noisy. It is composed of manufacturers who are anxious to obtain a special color "without which their industry will perish from the face of the earth." Mr. Thompson did not think the position of these manufacturers was at all justified. He said that his company had been able to accomplish all of its numerous dyeing effects with American colors pieced out with German reparation dyes obtained through the Textile Alliance. The third group is the friends of the importers who will sign anything which the importers put in front of them.

Opposition to Dye Industry Will Drive Consumers Into the Hands of the Cartel

Mr. Thompson could not understand why adequate protection to the organic chemical industry should be opposed, when such opposition, if successful, would land us with the hands of the German dye cartel at our throats. In reply to a question by Senator Shortridge Mr. Thompson said that he was convinced that a protective tariff would not adequately protect the industry.

He presented some interesting figures on the price of about eighteen dyes which his company purchases on a competitive basis and showed that the price within the last 18 months had dropped 50 per cent as a result of the strenuous competition. This certainly indicated the reverse of a monopoly. In conclusion he said that users of dyes generally supported the present legislation and that the cotton industry as a whole would welcome its continuation.

Herty's Accuracy and Motives Attacked by Members of Metz' Staff

He was followed by Eugene R. Pickerell, of the staff of Herman A. Metz, who began by attacking both the accuracy and the motives of the report submitted by Charles H. Herty, president of the Synthetic Organic Chemical Manufacturers Association. The report makes five points: 1. The German pre-war prices of dyestuffs were no less than those obtained on the home market during 1921. 2. Variations in the home market price averaged 356 per cent. 3. Export sales prices varied 617 per cent during the same period. 4. German export prices to the U. S. were three to fourteen times the pre-war prices. 5. Germany can manipulate prices so as to offset the protection given by any duty.

Dr. Pickerell stated that these figures were not fair, that they represented eighty dyes picked out to show maximum variations, that the variations were entirely due to fluctuating exchange and that while many of the German dyes were down to pre-war basis the American dyes were selling at three times the pre-war values. He further states that the American toy and surgical instrument industry has more difficult problems to face than the dye manufacturers.

The dye manufacturers will answer these statements at the hearings this week.

Metz Fails to Produce Evidence That the Dermatological Institute Is a Commercial Organization

To the unbiased observer this particular controversy must seem irrelevant to the main subject and rather inspired by a personal malice than by an earnest desire to see justice done. The testimony of Jay F. Schamberg, director of the institute which manufactures salvarsan, was given last week. He was cross-examined by A. C. Vandiver, attorney for H. A. Metz. The substance of the cross-examination was to prove that the Institute should not be exempt from income taxes, since it was competing in the market with commercial firms. It developed in the testimony that all of the profits from the sale of salvarsan manufactured by the Institute are invested in research work and that not one penny of it is taken for personal profit. Furthermore that the Institute could not compete with Metz recently and the latter had obtained all the cream of the government orders. Senator Shortridge remarked that if institutions like the Dermatological Institute were not permitted to compete with commercial firms it would at once sweep away all charitable work by doctors and lawyers, eliminate free hospitals and reduce everything to a commercial basis. Dr. Schamberg said that the Institute in its whole existence could not boast of profits such as Mr. Metz had made in any single year.

Acceptance of Ford Offer Unlikely, but Congress Will Authorize Completion of Dams

That Congress cannot accept or reject the Ford or any other Muscle Shoals offer has been emphasized since the return to Washington of the Senators and Representatives who recently paid a visit to the project. To bargain and to adjust contracts is a function for which Congress is not equipped. For that reason there is increasing support for Representative Kahn's proposal that a commission study the problem and recommend the specific legislation desired. In the meantime the government can carry along the construction of the dam and in that way clear itself of any charge of a policy of delay. Since it will take 3 years to complete the dam, there would be ample time for the commission to deliberate and for Congress to pass upon the legislation which would be recommended and be in a position to make a more intelligent decision without having held up the project. This will permit the administrative departments of the government, which are accustomed to the negotiation of contracts, to approach the proposition in a business-like way.

One effect of the discussion of the various offers has been to make practically certain that Congress will appriate sufficient funds to keep the work going on the dam. There is reason to believe that the Senate will approve a rider on the War Department appropriation bill providing about $7,000,000 for the work during the next fiscal year.

Hearings on the whole proposition have been begun by the Senate Committee on Agriculture. The Kahn committee, which recently completed the hearings on the House side, is now meeting in executive sessions to determine its course.

Officers of Synthetic Organic Chemical Manufacturers Association Elected for 1922

The Synthetic Organic Chemical Manufacturers Association of the United States held its first annual meeting at the Hotel Pennsylvania on Friday, March 31.

Officers for the ensuing year were elected as follows: President, Charles H. Herty; vice-presidents: Dyestuff Section, C. N. Turner, Newport Chemical Works, Passaic, N. J.; Intermediate Section, Charles A. Meade, E. I. du Pont de Nemours & Co., Wilmington, N. J.; Pharceuticals Section, Herman Seydel, Seydel Manufacturing Co., Jersey City, N. J.; Fine Organic Chemicals Section, P. Schleussner, Roessler & Hasslacher Co., New York City; treasurer, Donald McKesson, McKesson & Robbins, New York City; board of governors, vice-presidents, *ex officio*, and August Merz, Heller & Merz, Newark, N. J.; F. P. Summers, Noil Chemical & Color Works, New York City; Dr. S. Iserman, Chemical Co. of America, New York City; F. E. Singer, Butterworth Judson Corporation, New York City; W. T. Cashman, Grasselli Chemical Co., Cleveland, Ohio; S. W. Wilder, Merrimac Chemical Co., Boston, Mass.; Dr. A. S. Burdick, Abbott Laboratories, Chicago, Ill.; Donald McKesson, McKesson & Robbins, New York City; F. L. McCartney, Monsanto Chemical Works, St. Louis, Mo.; James T. Pardee, Dow Chemical Co., Midland, Mich.; Dr. Charles H. Herty, *ex officio*.

World's Largest Dam Part of Plans for Hydro-Electric Development in France

A tremendous hydro-electric power development, projected by a financial and economic group in central France, has been welcomed by the Minister of Public Works and approved by the Superior Council of Public Works. The report of this body states that before the end of this year the total water power developed in France will be 1,500,000 hp., or twice the total developed before the war. During the next 15 years it is hoped that a supplementary 3,000,000 hp. will be added.

The undertaking comprises the construction of four dams and four electrical plants at the estimated cost of 400,000,000 francs. The largest of these dams will be 114 meters high, including the base, or 35 meters higher than the Roosevelt dam. A million cubic meters of masonry would be used in the construction and the cost would be approximately 100,000,000 francs. This wall would form a reservoir covering 1,000 hectares, including the sites of eight towns. The plant at the base would be equipped to generate 150,000 hp.

When these proposals have been realized, the rivers Rhone, Dordogne and a part of the Rhine, together with all the waterfalls in the central mountain region, in the Pyrenees and the Alps, will have been brought under contribution. Shortage of labor combined with high cost of materials may, however, interfere with the realization of existing plans. Net cost of the works required to produce 1 kw. varies between 1,500 and 2,000 francs or $135 to $180 at present exchange rates. About 3,500,000,000 francs, or $350,000,000, will be required during the next 15 years.

Estimates place the total available hydro-electric power of France at 8,500,000 hp. The principal purpose to which it is proposed to divert the power thus brought under contribution is electrifying the French railroads. Estimated annual saving in coal would be 3,000,000 tons, over 5,000 miles of track. It would also be employed in French blast furnaces. The Council of Public Works does not recommend the harnessing of French streams and rivers for purposes of local lighting and motive power, except to a minor extent, but holds that the power would be best employed in a centralized form.

Hydro-Electric Development of Colorado River Would Harness Country's Greatest Power Source

The Colorado River Commission, of which Secretary of Commerce Hoover is chairman, is considering the problem of utilizing the 6,000,000 hp. available and at the same time meeting the irrigation needs of that section. Meetings of the commission began on March 15, at Phoenix, Ariz. The commission includes representatives of the seven states that contain parts of the Colorado River basin, Arizona, California, Colorado, Nevada, New Mexico, Utah and Wyoming.

The first construction in the great development recommended by the Reclamation Service would be a dam at Boulder Canyon, Arizona, 600 ft. high. This would make available 500,000 hp., or nearly as much as that developed now on both the American and Canadian sides of Niagara.

The progress in long-distance electrical transmission will yet bring all possible power of the river into national use, it is predicted.

Must Lower Freight Rate on Acid

Contentions of the American Zinc, Lead & Smelting Co. that the freight rate on sulphuric acid in tank car loads from Hillsboro, Ill., to certain Ohio River crossings are too high were upheld by the Interstate Commerce Commission in a decision handed down March 8. The smelting company manufactures sulphuric acid at Hillsboro. Its principal competition comes from the sulphuric acid manufactured at Copperhill, Tenn. On March 1, 1921, increased rates were put into effect from Hillsboro to the Ohio River. Since that time, however, there have been various readjustments in rates which have been to the advantage of the producers at Copperhill. Under the new ruling lower rates must be put into effect.

Pulp and Paper Industries in Maine Developing Hydro-Electric Resources

The Central Maine Power Co. has been very active during the past year in developing hydro-electric power. At a recent meeting all of the officers were re-elected. H. D. Eaton of Waterville is president.

The Kennebec Pulp Co. of Skowhegan, Maine, has lately undergone several changes. Water power will be replaced by hydro-electric power. One large motor of 750 hp. and four small motors will be installed. This mill has been closed since last summer. It is reported that it will furnish the Keys Fibre Co. of Waterville, Maine, a considerable quantity of ground wood pulp.

J. A. Harris, general manager of the Oxford Paper Co., Rumford, Maine, announced Thursday, March 2, that his company had taken over the interests of the Rumford Falls Power Co. The power company operates a modern hydro-electric plant with present installation to develop 31,000 hp. The paper company thus assures itself of ample water and power supply for present and future needs.

Rumors are circulating that hardwood furniture factories may be located in Maine in the near future. This seems very probable since evergreen forests cut some decades ago have been replaced by hardwoods which are now abundant. Hydro-electric power is available at low cost. Efforts to utilize hardwoods for pulp manufacture are being made, but are not likely to lead to important commercial results in the near future.

Seven Terra Cotta Firms Indicted by Federal Grand Jury for Practice of "Open Competition"

Indictments charging conspiracy and monopoly in restraint of trade were returned against the following manufacturers of terra cotta by the federal grand jury on March 27:

American Terra Cotta & Ceramic Co., Chicago, W. D. Gates, president; Denver Terra Cotta Co., Denver, George P. Fackt, vice-president; the Midland Terra Cotta Co., Chicago, Hans Mendrus, president; Northwestern Terra Cotta Co., Chicago, Harry J. Lucas, vice-president; St. Louis Terra Cotta Co., St. Louis, R. F. Grady, vice-president; Western Terra Cotta Co., Kansas City, William Timmerman, president; Winkle Terra Cotta Co., St. Louis, John G. Hewit, vice-president.

The indictments charge that the companies, as members of the National Terra Cotta Society, participated in the so-called Eidy plan of open competition, the same plan that was condemned by the United States Supreme Court in the hard-wood lumber case.

According to the indictments, the terra cotta society divided the country into eastern, central and western districts. Manufacturers in one, it is charged, withheld from competing in another.

The indictment charges that each company reported daily on its transactions to district headquarters, which in turn informed the other members.

New German Nitrate Plant Reported

The *Berliner Tageszeitung* reports that a new nitrogen company has been formed at Munich named "Cosag" (Continentale Stickstoffwerke Aktiengesellschaft). The capital is fixed at 40,950,000 marks. The company will erect its first nitrogen works at Golling, near Salzburg, and has acquired the right to exploit valuable lime deposits situated only a few hundred meters from the site of the new works. Rights have also been acquired in connection with the use of current from electrical works now in course of construction.

Discussions at National Foreign Trade Conventions

"Financing and Expanding Foreign Trade" will be the basic theme of the Ninth National Foreign Trade Convention, which will be held in Philadelphia, Pa., May 10, 11 and 12. Leaders in American industry, commerce and finance will be among the thousands of delegates from all parts of the country who will study the problem of how to finance and expand the nation's foreign commerce.

Farmers Register Protest Against Duty-Free Oils —Claim Soap Lobby Threatens Dairy Products

Farm organization delegates from fifteen different states made a concerted, eleventh-hour effort on March 24 to obtain a pledge from the Senate Finance Committee that tariff protection would be given dairy products, fats and oils, against Oriental and South Seas competition which threatens if the tariff oil schedule goes through as it now stands.

They savagely attacked the so-called "soap lobby," declaring its demand for duty-free vegetable oils would sacrifice the prosperity of nearly 40,000,000 farmers and endanger the $70,000,000,000 capital now invested in American farms and dairies.

Senator Townsend read a bundle of telegrams just received from Michigan dairymen and farmers and agricultural college experts, which denounced the growing tendency for substitution of cheap vegetable oils in daily foods, referring especially to "oiled" milk, lard compounds, salad dressings, filled cheese and the like.

Chairman McCumber of the Finance Committee seemed to agree with the trend of thought by saying: "It seems hardly proper that one section of the country should live under the protection of high duties while another section of our people should be forced to meet the competition of the world's free trade." He inquired if the farmers' committee would favor a tariff that taxed vegetable oils destined for food uses, but admitted free such oils as would be used in soap-making.

C. F. Creswell, statistician of the Dairymen's League, presented evidence showing the immense amount of soya bean oil, copra and coconut oil, peanuts and peanut oil which would flow into this country from Manchuria and the tropics, where the yellow and brown races have well developed and growing industries.

The Senate Finance Committee has received about 25,000 letters from laundries and grocery men, instigated by the "soap lobby," according to Senator Calder, so a bitter contest is expected by the farmers.

Garabed Bobs Up Again to Aid Agriculture

Taking a leaf evidently from Henry Ford's book, Garabed T. K. Giragossian, through the instrumentality of Representative Riddick of Montana, again has placed his unlimited energy invention before Congress, this time with the idea of "aiding agriculture by providing facilities for nitrate plants, water for irrigation, and for promoting more efficiency in travel and transportation, through the elimination of expense or labor for motive power."

The resolution which passed Congress Feb. 8, 1918, has been amended by striking out the assertion that Giragossian is the first and original inventor or discoverer of the process. The new resolution provides "that any invention or discovery similar to the claim of Garabed T. K. Giragossian shall not have come into actual and general public use and demonstrated in a substantial manner to be feasible and practical prior to the demonstration of the 'Garabed.'" The resolution also states that "Garabed" is not electricity.

While Congress is no more skeptical of this alleged discovery than it was in 1918, the original resolution was passed when the country was desperately in need of additional power. Congress was ready to grab at any straw which carried with it the barest possibility of speeding up the war program. Under present conditions it is regarded as practically certain that no serious consideration will be given this proposition by Congress.

Water-Testing Methods Described

"Field Examination of Water," by W. D. Collins, has just been prepared as a mimeographed summary of the recommendations of the U. S. Geological Survey, superseding its earlier report on methods of field assay of water. Methods are given for determination of turbidity, color, iron, chloride, carbonate and bicarbonate, hardness, sulphate and calcium, and for computation of results. Those desiring a copy of the report can get it on application to the author at the U. S. Geological Survey, Washington, D. C.

March Meeting of Lehigh Valley Section of the A.C.S.

The Lehigh Valley Section of the American Chemical Society met in the Administration Building of Muhlenberg College, Allentown, Pa., on Thursday evening, March 30. Prof. S. W. Parr, head of the department of applied chemistry, University of Illinois, spoke on "Fuels."

Dr. Parr's discussion centered on the theory of coking or carbonization of coals and on the results obtained by him in his researches. He has developed a method of coking the so-called non-coking Illinois coal so as to make it suitable for domestic purposes.

International Nickel Co. Centralizes Research and Development Activities

Robert C. Stanley, formerly first vice-president, was recently elected president of the International Nickel Co. Mr. Stanley has ordered a reorganization of personnel, involving as its chief feature a new department of development and research with headquarters at 67 Wall St., N. Y.

The new department of the company is the outgrowth of a gradually maturing conviction that a study of its products and their successful use in the hands of the consumer is the key to the extension of tonnage distribution. Research departments at the mines, smelters and refineries of the company, established during the last few years, have now been crystallized into a headquarters organization in intimate contact both with its own plant developments and with outside engineering developments, touching on the use of nickel and Monel metal in all fields. This department will be under the direction of A. J. Wadhams, manager. Associated with him will be Dr. Paul D. Merica, director of research.

Mr. Wadhams has hitherto been manager of the large Bayonne refinery of this company and has for years been in direct charge of the manufacture of all of the company's products, and through this experience is fitted to an unusual degree for his new work.

Trade Associations to Be Studied for the U. S. Chamber of Commerce

A committee has been appointed by the Chamber of Commerce of the United States to study trade associations. The committee will concern itself chiefly with the service which trade associations can render to business and to the public. The members of the committee are:

Philip H. Gadsden, chairman, Philadelphia; president, American Electric Railway Association and formerly member of Federal Electric Railways Commission; vice-president, United Gas Improvement Co.

Thomas S. Adams, New Haven, Conn.; secretary, National Tax Association; professor of political economy, Yale University.

Fred R. Babcock, Pittsburgh; formerly president, National Wholesale Lumber Dealers' Association and of the Pittsburgh Chamber of Commerce; president, Babcock Lumber Co.

Charles J. Brand, Pittsburgh; formerly chairman, Cotton Distribution Board, and chief of Bureau of Markets, Department of Agriculture; vice-president and general manager, United Fruit Growers, Inc.

Henry S. Dennison, Framingham, Mass.; formerly director of planning and statistics, War Industries Board, and president of the Taylor Society; president, Dennison Manufacturing Co.

James R. Maccoll, Pawtucket, R. I.; formerly president, National Cotton Manufacturers' Association and chairman executive committee, World Cotton Conference; treasurer, Lorraine Manufacturing Co.

J. D. H. Morrow, Washington; vice-president, National Coal Association.

Alfred Reeves, New York; secretary, National Automobile Chamber of Commerce.

George Rublee, New York; formerly member of Federal Trade Commission and delegate to Allied Maritime Transport Council.

Imports and Exports of Chemicals

Imports of chemicals on the free list during February were valued at $4,044,647. The imports of dutiable chemicals were valued at $2,713,180. This shows a decrease as compared with February of 1921, when imports of free list chemicals were valued at $5,306,361. The imports of dutiable chemicals in February, 1921, were valued at $2,129,903. The figures are those of the Bureau of Foreign and Domestic Commerce.

The principal increase in importations was in the gum group. There was a decided increase in the imports of chicle and in camphor. Imports of coal-tar products remained at practically the same level as in February, 1921. There also were increased importations of alkalis and alkaloids. There was a heavy decline in imports of calcium products.

Exports of chemicals continued to decline during February. The value of all chemicals exported was $7,665,830. In February of 1921 the value of chemicals exported was $10,559,429. As compared with February of last year, the principal decline was in the coal-tar group, in pigments, paints and varnishes, in fertilizers and in calcium compounds. Acetate of lime was an exception in this latter group. Exports of that commodity in February, 1922, were nearly double those of 1921. Exports of explosives increased decidedly, as did those of caustic soda.

Canadian Concern Lands Large American Order by Virtue of Low Merchant Marine Freight

Owing to the fact that the Canadian Government Merchant Marine was able to quote a low freight rate, the Sidney Roofing & Paper Co. has obtained an order for 1,400 tons of roofing felt from a concern in Los Angeles. This order will keep the plant, which since the fire last year has been moved from Sidney to Victoria, busy for 2 months.

In connection with the above it its interesting to note that the Canadian Government lost $2,210,724 in operating its merchant marine in 1921, excluding depreciation and interest charges. Interest owed the government for 1921 was $3,357,833.39. Depreciation was figured at $4,158,775.51.

Reorganization of Canada Pulp & Paper Co. Involves Unusual Legal Entanglement

With a view to the reorganization of the Canada Paper & Pulp Co., Ltd., which erected a plant and acquired extensive limits at Port Mellon, on Howe Sound, B. C., the Chartered Trust & Executor Co., as trustee for the holders of 7 per cent first mortgage gold bonds to the value of $1,000,000 in the paper concern, is suing the paper company and has named itself as one of the defendants, because it is also trustee for holders of a simultaneous issue of 6 per cent redeemable debenture stock, the owners of which are likewise interested in the reorganization. While this seems to be rather a complicated legal tangle, it is understood to be really a friendly suit to clear the way to a reorganization of the concern. The Western Pulp & Paper Co. was formed during the period of the boom in newsprint, but the plant now has been idle for several months.

Interstate Commerce Commission Regulations for Shipment of Explosives and Poisons

Regulations effective March 20 affecting the transportation of explosives and other dangerous articles have been promulgated by the Interstate Commerce Commission in Order 3666. The order includes regulations for the transportation of explosives by freight, including ammunition for cannon, chemical warfare ammunition and explosive bombs and mines of all kinds. Required methods of packing, marking and certifying these explosives are covered in detail. Rules for the handling and waybilling of acceptable explosives are expounded. A second section of the order covers the regulations for dangerous substances other than explosives, including prussic acid, bromacetone, brombenzylcyanide, carbonylchloride, chlorpicrin, cyanogen, mustard gas, police gas grenades and xylyl bromide.

French Chamber of Deputies Supports Private Operation of Alsatian Potash Deposits

The French Chamber of Deputies has recently been discussing the future régime to be applied to the Alsatian potash mines sequestrated by France. The commission formed to deal with the question had recommended that the mines be exploited by three companies to which concessions should be given. This recommendation was upheld by the government on the ground that competition among the three different companies would increase production and keep prices down. The Chamber voted against a counter-proposal by which the mines would remain entirely state controlled, but adopted by a vote of 289 to 250 a second counter-proposal by which the concession would be given to a single company, in which the workers themselves would have shares, in conformity with the law of April 26, 1917. The commission will now have to study this proposal and present another report.

Meeting of the American Electrochemical Society in Baltimore Announced

Preliminary announcements have been made of the program of the spring meeting of the American Electrochemical Society in Baltimore. The convention will meet first at the Emerson Hotel Thursday morning, April 27.

The morning will be devoted to a symposium on electric cast iron in charge of A. P. Hinckley and Bradley Stoughton. A golf tournament and visits to industrial plants will divide the honors in the afternoon. In the evening the members will have the privilege of hearing Prof. R. W. Wood of Johns Hopkins on the subject of fluorescence.

A number of timely papers are listed for the meetings Friday and Saturday morning as well as the presidential address of the retiring president, Acheson Smith.

It is urged that those who plan to attend should engage hotel accommodations at once. W. H. Boynton is acting as chairman of the local committee.

Present Status of Calvert Process for Alcohol From Water Gas

Owing to occasional references in current publications to the so-called Calvert process for making alcohol from water gas and hydrogen, inquiries have been made in England to determine the true status of the process.

The inventions of Dr. Calvert have to do with the production of both ethyl and methyl alcohols from carbon monoxide and hydrogen, the production of the latter being in a more advanced stage than that of ethyl alcohol, which is a later invention. A small test plant is now in process of construction, but present information does not extend beyond laboratory results. The production of both alcohols consists in running mixed carbon monoxide and hydrogen gases at controlled temperature and pressure over a catalyst producing either of the desired alcohols and an excess of CO. Approximate theoretical yields are not yet in sight.

Civil Service Examination Announced for Assistant Examiner, Patent Office

The U. S. Civil Service Commission announces an examination for assistant examiner in the Patent Office. Examinations will be held on May 10, 11 and 12 and on June 21, 22 and 23. The salary is $1,500 and applications must be filed on Form 1312. Subjects include mathematics, physics, mechanical drawing, language, technics and one optional.

Peat Bogs of Maine to Be Exploited

A contract probably has been, or will be, signed by the Peat Engineering Co., of Bangor, Maine, and others for the construction and operation of a peat plant, with sales rights in Penobscot County. Penobscot County includes the cities of Bangor, Dexter and Old Town. The stockholders of the Peat Engineering Co. have voted to ratify a contract with F. T. Dow, inventor of equipment to dry peat. This operation will be watched with much interest, as there are numerous peat bogs in Penobscot County.

Association of Chemical Plant Equipment Manufacturers Will Organize

The organization committee of the Association of Chemical Plant Equipment Manufacturers will call a meeting to be held in New York during the week of May 8 to perfect a permanent organization of the association.

It is expected that the meeting will be addressed by Secretary Hoover and Dr. Julius Klein of the Department of Commerce on the value of industrial associations. There will also be several other speakers who have had practical experience in running expositions and shows.

Definite dates of the meeting will be announced in a later issue.

Bureau of Chemistry Arranges Dust Explosion Exhibit

The engineers of the Bureau of Chemistry have arranged an exhibit showing the need for preventive measures to avoid dust explosions and fires. The exhibit is arranged in three panels. One panel is devoted to grain milling and other food product industries. The second panel is devoted to threshing machines and the method of avoiding danger from fires when threshing is done in dry weather. The third panel is devoted to cotton gin fires. These fires are of almost explosive violence once they are started. Accompanying the exhibit is a stereomotorgraph showing plants wrecked by explosion and fire. The entire exhibit may be obtained by applying to the Department of Agriculture in Washington. It should be in great demand by persons and organizations interested in fire prevention.

A.C.S. Intersection Meeting to Be Held at Akron

Members of the Cleveland Section of the A.C.S. will be the guests of the Akron Section on May 3. The day will be spent in visiting the industrial plants in Akron and in games of various kinds. A dinner will be held in the evening at which Prof. Edgar F. Smith, president of the American Chemical Society, will be the principal speaker.

Dr. W. C. Geer is chairman of the Akron committee.

Examination for Junior Technologist Announced

Examinations for junior technologist in the Bureau of Standards and elsewhere will be held on May 24, July 5 and Aug. 23. Subjects in which examinations will be held include general chemistry and elementary physics, 20 points; mathematics, including calculus, 25 points; practical questions on optional subjects, including the technology of rubber, leather, paper, textiles, oil, and general, 30 points; education, training and experience, 25 points. Salary at the start will be from $1,200 to $1,500 per year. Application must be made on Form 1312 to the Civil Service Commission.

Personal

D. D. Berolzheimer has been appointed manager of the information bureau of the Chemical Catalog Co., Inc., and of the service department of the *Journal of Industrial and Engineering Chemistry.*

J. Parke Channing, president of the Seneca Copper Co., 11 Broadway, New York, has resigned. First Vice-President Linton of the company will act as president until a successor is chosen.

O. L. Chormann spoke before the regular meeting of the Rochester, N. Y., Section of the American Chemical Society, April 3, on "Pasteurization of Milk Under Vacuum."

Colonel J. K. Crain is to succeed Major J. H. Burns as head of the Ammunition Division of the Ordnance Department of the Army, a division which includes the important nitrate section. Major Burns is relieved because of the statutory requirement limiting service in Washington to 4 years. He goes to San Francisco to become the corps-area ordnance officer for the Ninth Corps Area. Captain D. P. Gaillard, who has been in charge of the nitrate section of the Ammunition Division, has been made commanding officer at the Old Hickory powder plant. P. E. Howard has succeeded him as chief of the nitrate section.

Thomas French is establishing a works in New York for the manufacture of certain colors similar to those made under his patents in Canada.

Alvin C. Goetz, for the past 3 years with the byproducts division of the Southern Cotton Oil Co., has resigned to accept the superintendency of one of Darling & Co.'s fatty acid distilling plants at Chicago.

Charles E. Golding, of Trenton, N. J., manager of the Golding Sons' Co., producer of feldspar, flint, etc., has resigned to become head of the Golding-Keene Co., recently organized to engage in a kindred line, with headquarters at Trenton.

H. W. Hardinge has returned from a business trip through England, France and Belgium.

Dr. R. B. Moore, chief chemist of the U. S. Bureau of Mines, expects to sail on May 6 for a 2 months' trip to Europe on professional business. He will visit France, Germany, Austria, Czechoslovakia, Holland and Belgium.

H. C. Parmelee, editor of Chemical & Metallurgical Engineering, was married on April 10 to Miss Eugenia McAusland, of Washington, D. C. They will be at home after May 15, corner of Spring and Lefferts Roads, Yonkers, N. Y.

E. C. Reeder, for the past 5 years chief engineer of the Rosiclare Lead & Fluorspar Mining Co., in charge of exploration, development and construction work at Rosiclare, Ill., resigned on March 1, to enter the employ of the Hillside Fluorspar Mines, of the same place, in a similar capacity.

R. T. Stull, who for several years has been superintendent of the Columbus (Ohio) Experiment Station of the Bureau of Mines, has been appointed assistant chief of the bureau's mineral technology division. In that position he will have technical supervision over the work in non-metallics and in ceramics.

Prof. The. Svedberg, of the University of Upsala, Sweden, will organize and direct the research work in colloid chemistry at the University of Wisconsin during the second semester of 1922-23 and the summer session of 1923, and will also give two lectures each week on the subject and conduct two weekly seminaries. During the summer session of 1923, lasting 6 weeks, the lectures given during the second semester will be repeated for the benefit of educators and research workers who find it impossible to attend the university during the regular session. A seminary will also be conducted through the summer session.

Prof. Maximilian Toch delivered a lecture at Cooper Union on April 3, on "Chemistry and the Next War," which was illustrated by two reels of moving pictures showing post-war government experiments on bombing operations.

Dr. Charles Wadsworth, 3d, of Chicago, has joined the staff of Chemical & Metallurgical Engineering as Assistant Editor, with headquarters in New York. Until recently he was in the operating department of the Grasselli Chemical Co.

Obituary

William F. McNabb, of Pittsburgh, Pa., secretary and treasurer of the Vanadium Metals Co., Vanadium Building, that city, died on March 27, of self-inflicted injuries in a Mount Clemens, Mich., hotel, where he had gone to regain his health. He was 36 years of age and was prominently connected with local industry, being also treasurer and director of the Flannery Zinc Co. and assistant treasurer of the Pittsburgh Electric Furnace Co.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

The Chemical Industries and the Stock Market

Coincident with the recent upward trend in wholesale prices there has been a noticeable recovery in the stock market. This return of confidence in business, while perhaps more or less psychological, augurs well for the immediate future of industry.

That the stocks of companies in the chemical and allied industries have followed somewhat the same trend as the general market is evidenced by the accompanying tabulation. For the purposes of this comparison, twenty representative companies operating in the field served by CHEMICAL & METALLURGICAL ENGINEERING were selected and the average price of their stocks was compared with the *Annalist's* averages for twenty-five general industrials and for twenty-five railroad stocks. It will be observed that the curve representing the chemical company stocks has followed with rather striking similarity that of the average for the industrials. The spread between the two curves was practically constant in 1917 and 1918. During the sharp rise that occurred in the first half of 1919 the two curves were almost together. While the chemical stocks, after reaching a peak in July, 1919, continued to show the same general tendencies as the industrials, the recoveries of the former were less effective and the falls more pronounced. The *Annalist* average reached its peak in October, 1919. Neither curve again attained this high level, although in April, 1920, the industrials came within a few points of its former high.

COMPARISON OF PRICES OF CHEMICAL, INDUSTRIAL AND RAILROAD STOCKS

In the decline of 1920 and 1921 it is of interest to note that both curves touched bottom in the same month, August, 1921. The chemical company stocks were practically 15 points beneath their previous low recorded in December, 1917. In the case of the industrials, however, the August, 1921, quotation was still at least a few points above that at the end of 1917. The present upward movement began in August of last year and has proceeded without interruption for the past 7 months. Apparently the average for the twenty-five railroad stocks has also participated in this advance, notwithstanding the fact that since 1918 the curves for industrials and railroads have had but little in common. The outstanding characteristic of the latter stocks during the last 5 years has been their comparative stability as evidenced by the absence of any wide fluctuations.

The companies whose stocks were used for this compilation were selected as representing the principal chemical and chemically controlled industries. The quotations used were the bid prices for common stock adjusted to the basis of a par of 100 and averaged on or about the first of each month. In the case of practically all of these companies their stocks are listed on the New York Stock Exchange. Included in the average are the following: Allied Chemical & Dye Corporation, American Agricultural Chemical Co., American Cotton Oil Co., American Linseed Co., American Smelting & Refining Co., American Sugar Refining Co., Central Leather Co., Corn Products Refining Co., Davison Chemical Co., E. I. du Pont de Nemours & Co., International Nickel Co., International Paper Co., Mathieson Alkali Works, National Lead Co., Texas Co., United Dyewood Corporation, United States Cast Iron Pipe & Foundry Co., United States Rubber Co., U. S. Industrial Alcohol Co., and Virginia-Carolina Chemical Co.

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

This week	158.36
Last week	156.75
April, 1917	207
April, 1918 (high)	286
April, 1920	261
April, 1921 (low)	140

The gain shown in the index number over last week is due to the rise in price of cottonseed and linseed oil, as well as ammonium sulphate. These higher prices more than offset the slight price reductions in acetic and citric acids, barium chloride, borax, caustic soda and caustic potash.

An Outside View of the Industrial Chemical Market

It is occasionally of interest to get an outside viewpoint on market conditions within the chemical industry. Such a view is afforded in the following statement extracted from a recent industrial letter of the Babson statistical services. While we are inclined to agree with Mr. Babson's views in regard to lowered costs and continued readjustment, we do not believe he is entirely justified in his inference that lower prices can be expected for such staples as alum, bleaching powder and caustic soda.

"The worst of the industrial chemical readjustment is definitely over, yet this does not necessarily mean that the minimum price basis is established. A lower plane is entirely probable. Industrial chemicals represent another group that experienced abnormal expansion to cope with the war demand. Even in the days of urgent demand there was no shortage. Consequently, our total producing capacity today, compared with actual needs, is exorbitant. Since early in 1920 competition has constantly increased.

"The price alignment has marked time more or less with the revision in producing costs, and the cost of production is

destined for lower levels. Incidentally, Europe is in the same category. Her producing ability is large and channels of consumption restricted. Our imports have naturally declined, but our exports have also recorded a drastic setback.

"We cannot disregard the fact that we are still in a period of depression, a condition that will not terminate for some time to come. Industrial activity will improve only gradually, particularly as some of our major industries have yet to complete the transitionary process. The demand for industrial chemicals this year will not be large. The average price is fully above 1913. From a comparative standpoint this is not high, but the unusual conditions that prevail suggest conservatism in such chemicals as alum, bleaching powder, caustic soda and soda ash. A constant supply is the primary incentive."

Better Technology an Imperative Need in the Chilean Nitrate Industry

That Chilean nitrate will continue for a long time to be an important source of fixed nitrogen, in spite of developments which may be made in the technology of nitrogen fixation, is the opinion of Paul F. Holstein of Chicago, an American chemical engineer with 10 years' experience in the nitrate fields, having been assistant manager of one of the American plants. In a recent interview he summarized some of the more important factors affecting the economic outlook for this industry.

Facts which must not be lost sight of are that over $200,000,000 has been invested in this industry and that in the past it has been possible by working the richest caliche to obtain a very substantial return on the investment and still sell under a high government tax. Under such conditions pleas for improved technology received scant attention. More recently, however, it has become necessary to work deposits containing only 17 or even 15 per cent of nitrate instead of 30 to 50 per cent and in addition competition has arisen in the form of synthetic nitrogenous materials.

A thorough study of methods for reducing the production costs of Chilean nitrate is becoming imperative. There are two well-defined lines of approach—the government tax and technology.

Since the beginning of the industry the nitrate tax has enriched the Chilean treasury by about $500,000,000. About two-thirds of the income of the Chilean Government is derived from this source and there is not much in the way of an alternative, so that the tax will probably remain, unless the industry should be seriously threatened. In such an event the government would have to take drastic measures for self-preservation.

Turning to the technology, much room for improvement is seen in the average plant and it has been estimated that a 40 per cent reduction in cost should be possible through improved processes. Better recovery, more efficient fuel utilization, and improved mining methods are problems which, when solved, will do much to decrease the cost of production. In many of the plants at present 30 to 33 per cent of the total cost of the finished nitrate at the plant is charged to fuel, while placing the ore at the plant accounts for 45 per cent more.

Since prices are controlled through a central association, it would seem quite possible for this organization to assist in the technological development rapidly becoming essential to the existence of the industry in the face of competition.

The New York Market

New York, April 10, 1922.

A slight improvement was reflected in the volume of chemical business during the past week and although conditions in general are far from normal, the tendency is toward betterment. Caustic soda producers report a heavy call for contract shipments and large tonnages have been moved from the works. There was also a decided improvement in the demand for copper sulphate, and heavy orders have been placed for foreign and domestic consumption. Barium chloride is still very scarce and prices have shown a net gain over the week. Sulphide of soda developed a firmer tone, owing to the reduction of imported stocks.

Arsenic.—There were a few sales noted at 7¼c. per lb. during the week and quotations ranged from 7¼@7½c. per lb. Futures were offered at 6¾@7c. per lb., depending upon quantity.

Barium Chloride.—Scarcity at present has created a very strong market and prices are steadily advancing. It was very doubtful if better than $87 per ton could be done at the close of last week. Some sellers were holding for $90 per ton. Domestic producers have been quoting $75 per ton, but practically all these sources are sold up to the latter part of June. Demand is very brisk.

Carbonate of Potash. — The 80-85 per cent material is showing additional strength in the resale market and large manipulators are not willing to quote below 5c. per lb. for prime goods. Quotations range from 4¾c. per lb. upward.

Caustic Soda.—Resale dealers quote the market at $3.60 per 100 lb. for export, April shipment from works. The market quieted down considerably during the week and foreign inquiries were not very noticeable. Producers, however, report a steady demand for contract shipments and quote the market firm at 2½c. per lb., basis 60 per cent, f.o.b. works, in carload lots.

Copper Sulphate. — There was a decided improvement noted in this commodity, especially from South American countries. The domestic inquiry has also shown improvement and the agricultural demand at present is very active. Considerable business was transacted to Middle Western farmers. Leading factors quote large crystals at 5½c. per lb. in carlots and $5.40 per 100 lb. for the smaller crystals. Some producers report a sold up condition on all large crystals.

Hyposulphite of Soda.—There were a few sales recorded during the week on the basis of $2.90 per 100 lb. for imported material. Domestic producers quote 3c. per lb. f.o.b. works. The demand has recently shown more activity and larger sales were recorded.

Prussiate of Soda.—Keener competition and a quiet inquiry have had a tendency to weaken quotations for imported material and sales were reported down to 16½c. per lb. The movement was practically confined to resale dealers.

Soda Ash.—Prices for spot material remained quotably unchanged. Carlots in single bags are quoted at $1.80 per 100 lb. and barrels at 2c. per lb. Leading producers quote contracts for light 58 per cent at $1.20@$1.25 per 100 lb. for single bags and $1.45 for barrels, basis 48 per cent, f.o.b. works.

Coal-Tar Products

There has been a marked improvement in this industry since our last report. Indications all around appear more favorable and the stability of prices throughout the list has restored the confidence of buyers. Resale material is not very plentiful. Producers report a livelier inquiry and it is very significant that passing business is being transacted by first hands. Price changes during the week have been very few. Those close to the pulse of trading believe that the recent recovery to more normal conditions is a very good sign that the bottom has been reached.

Cresol.—First-hand sales of U. S. P. goods are reported at 12@15c. per lb. Ortho-cresol is finding a fair outlet at 16@18c. per lb. The demand is moderate and confined chiefly to small quantities.

Naphthalene.—There has been a much better demand from various sources of seasonable character and resale dealers report additional inquiries. Prices are maintained in first hands. Balls are offered at 8c. per lb., flakes at 6½c. and crushed at 6@6½c. per lb.

Aniline Oil.—Supplies are liberal and the general condition of the market is hardly steady. Buyers have not shown any inclination to operate on a large scale. Producers quote the market at 16½c. per lb.

Benzaldehyde.—Small-lot sales have been the only feature of the market. Sales of the U. S. P. are reported at $1.25 per lb., while the technical is moving at 45c. per lb. The demand is moderate.

Toluidine.—Sales of the mixed have been transacted at 30c. per lb., with smaller lots held up to 35c. The demand is rather quiet, with passing transactions of a small nature.

The Chicago Market

CHICAGO, ILL., April 6, 1922.

The main feature of the industrial chemical market during the past 2 weeks was the firmness of prices. Practically no declines were to be noted and while actual advances were few, spot prices were very firm. Imported material is especially firm, with most stocks at a low point. Dealers and manufacturers are both apparently enjoying a good volume of business and seem to be fairly well satisfied. The trading is mostly in small-sized lots but it is noticeable that a few buyers are beginning to buy ahead.

GENERAL CHEMICALS

Caustic soda is in a firm position and is moving fairly well in small lots. Ground caustic, 76 per cent, is quoted at $4.35@$4.50 per 100 lb. and solid at $3.75@$4. *Caustic potash* is very firm, with spot stocks light. The high test, 88-92 per cent material is quoted at 6¾@7c. per lb. *Potash carbonate* has shown some signs of firmness and 96-98 per cent material is available at 10@12c. per lb. *Soda ash* is reported to be moving well and is unchanged at $2.30 per 100 lb.

Potash alum lacks quotable change at 5@6c. per lb. for the lumps and 6@6½c. for the powdered. *Sal ammoniac* is moving well at 7¾@8¼c. for the white granular. *Copper sulphate* is reported to be moving well and is very firm at 6@6½c. per lb. *Bleach* is moving fairly well at 3c. per lb. for large drums. *White arsenic* is in good demand and supplies are available at 8c. per lb. There is a good movement of *carbon bisulphide* and prices are firm at 6¾@7c. per lb. *Carbon tetrachloride* is unchanged as to price and is moving fairly well at 10½@11c. per lb. *Formaldehyde* is moving very well, but the price is weak due to competition and the weakness of the methanol market. Agents quote barrels at 9½@10c. per lb. and kegs at 11@12c. *Furfural* is enjoying a fair demand and is quoted in single drum lots at 50c. per lb. *Epsom salts* are moving in a routine way at 2¾@3c. per lb. for the U.S.P. crystals. Glycerine is rather quiet and refiners have announced nothing new in the way of prices. The c.p. material in drums is quoted at 16c. per lb. delivered. *Lead acetate* is quiet, with 12@13c. per lb. quoted on the white crystals.

Nothing new has developed with bichromates. The *potash salt* is quoted at 11¾@13c. per lb. according to the seller and *soda* at 9@9½c. The market is still bare of *potassium ferricyanide*. *Potassium ferrocyanide* is very firm and is moving well at 32@35c. per lb. *Permanganate of potash* is rather neglected and supplies are available at 18c. per lb. *Bicarbonate of soda* is moving in a routine way at 2¼c. per lb. There is a somewhat better demand for *sodium hyposulphite* and the price is unchanged at $3.95 per 100 lb. for the pea crystals in barrels.

LINSEED OIL—NAVAL STORES

Linseed oil continues to move very well in consuming channels. The price is firm and at least a few factors expect higher prices. Today's market was 86c. per gal. for the boiled oil in 5-bbl. lots and 84c. for the raw oil.

Turpentine is reported to be moving briskly and the price is firm. Today's market was 84½c. per gal. for 5-drum lots. *Rosin* is moving somewhat slowly and less than carlots of the WW grade was quoted today at $8.35 per 280 lb.

The Iron and Steel Market

PITTSBURGH, April 7, 1922.

Obviously it is necessary to dig beneath the surface to make an appraisal of the actual condition and prospects in the steel market. The superficial developments are increased demand, increasing production and stiffening prices in some steel commodities, definite advances in others. Superficially there is a great similarity to conditions that have existed in the early stages of all the periods of activity in the steel industry. It must be remembered that the steel trade has always been one of periods of activity interspersed by periods of inactivity. In periods of inactivity there have been starts toward full activity that were not carried to the end, and it has not always been possible to distinguish the one from the other.

At the present time opinion is divided. The facts as to orders are not subject to dispute, the question being as to the rate of consumption. Some argue that when buying of steel has been so heavy with consumption as it has been lately, increased consumption will bring heavier buying in future. Others argue that as consumption does not support the present rate of production the buying will decrease, part of the buying of late having been against replenishment of stock.

PRICES

Bars and shapes recently became quotable at 1.50c. as a general market price, as noted in this report a week ago. Plates seem now also quotable at the advanced figure, making the three heavy rolled products at 1.50c., against about 1.35c. a month ago. There are no rigidly maintained prices, however, in these commodities, concessions being no doubt given in some instances, while on the other hand small and undesirable orders command as high as 1.60c.

Effective yesterday, pipe mills decreased the preferential on plain end pipe from three points to one point, and on pipe with threads and not couplings from two points to a quarter point, beyond the regular discounts for pipe with threads and couplings. Shading of regular published prices has largely disappeared. In some quarters it is thought probable that a small advance in the whole pipe list will soon be made.

Practically all the sheet mills have now completed booking of business at the old prices and the $3 a ton advance announced some time ago by most of the mills as to become effective about April 1 may be regarded as in force. Meanwhile business has been brisk in actual shipping orders as well as in second quarter contracts. The new prices are: Blue annealed sheets, 2.40c.; black, 3c.; galvanized, 4c.; automobile sheets, 4.50c.

Wire products are very firm, plain wire being 2.15c. and wire nails $2.40. Demand for nails is excellent and for wire products in general is very fair.

PRODUCTION INCREASED

The rate of steel ingot production is now between 33,000,000 and 35,000,000 tons a year, having increased rather sharply in the past fortnight. The rate was about 29,000,000 tons at the end of February, and averaged 23,000,000 tons last October and November. Much question is raised as to the disparity between production and consumption, it being urged in some quarters that there is no appearance of such activity in steel consumption as was visible in 1912 and 1913, each of which years saw a production of 30,000,000 tons of ingots. Depletion and replenishment of stocks make a great difference, a fact illustrated by the production of ingots last July at only 11,000,000 tons a year, when obviously consumption must have been at a much greater rate.

The coal strike involves much more idleness at non-union mines than was expected, the lower Connellsville in particular being affected. There will be more drawing upon stocks of coal and coke in April and less non-union production than was expected. The strike at the union mines was generally expected to last 2 months or more, and an interesting question now is whether strikes in non-union districts will last long enough to be a factor at the end.

COKE AND PIG IRON

The Connellsville coke market has stiffened a trifle, spot and prompt furnace coke appearing firm at $3.50, when a week ago the market was quotable at $3.25@$3.50, there being odd lots to be picked up at the lower figure. Many furnacemen express themselves as quite averse to bidding for coke in case of a scarcity, preferring to bank furnaces and thus help their pig iron market, rather than pay extra prices for coke and thus help the coke market.

Pig iron is showing somewhat more activity in most districts and prices are stiffening. The valley market remains quotable at $19.50 for bessemer, $18 for basic and $19 for foundry, but confident predictions are made that the next important sales of basic and foundry iron will be at 50c. advance.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.30 — .31
Aniline oil, drums extra	lb.	.16½ — .17
Aniline salts	lb.	.24 — .26
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.25 — 1.30
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.75 — .85
Benzoic acid, U.S.P.	lb.	.60 — .65
Benzoate of soda, U.S.P.	lb.	.55 — .57
Benzene, pure, water-white, in drums (100 gal.)	gal.	.29 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.27 — .32
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.60 — .65
Beta-naphthol, tech	lb.	.28 — .30
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97–99%, straw color, in drums	gal.	.50 — .52
Cresylic acid, 95-97%, dark, in drums	gal.	.45 — .47
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	1.15 — 1.20
Dimethylaniline	lb.	.38 — .40
Dinitrobenzene	lb.	.23 — .25
Dinitroclorbenzene	lb.	.23 — .25
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.33 — .35
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Diphenylamine	lb.	.59 — .70
H-acid	lb.	.85 — 1.00
Meta-phenylenediamine	lb.	.90 — 1.00
Monochlorbenzene	lb.	.14 — .15
Monoethylaniline	lb.	1.20 — 1.25
Naphthalene crushed, in bbls.	lb.	.06 — .06½
Naphthalene, flake	lb.	.06½ — .07
Naphthalene, balls	lb.	.08 — .08½
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17½
Ortho-amidophenol	lb.	2.75 — 2.80
Ortho-dichlor-benzene	lb.	.15 — .20
Ortho-nitro-phenol	lb.	.75 — .80
Ortho-nitro-toluene	lb.	.12 — .15
Ortho-toluidine	lb.	.16 — .20
Para-amidophenol, base	lb.	1.25 — 1.30
Para-amidophenol, HCl	lb.	1.30 — 1.35
Para-dichlorbenzene	lb.	.15 — .18
Paranitroaniline	lb.	.75 — .77
Para-nitrotoluene	lb.	.70 — .75
Para-phenylenediamine	lb.	1.50 — 1.55
Para-toluidine	lb.	1.10 — 1.15
Phthalic anhydride	lb.	.35 — .38

Phenol, U. S. P., drums	lb.	11½	15
Pyridine	gal.	1 75 —	2.75
Resorcinol, technical	lb.	1 30 —	1.35
Resorcinol, pure	lb.	1.75 —	1.80
Salicylic acid, tech., in bbls	lb.	.23 —	.24
Salicylic acid, U. S. P	lb.	.25 —	.26
Solvent naphtha, water-white, in drums, 100 gal	gal.	.25 —	.28
Solvent naphtha, crude, heavy, in drums, 100 gal	gal.	.10 —	.12
Sulphanilic acid, crude	lb.	25 —	.27
Tolidine	lb.	1 20 —	1.30
Toluidine, mixed	lb.	.30 —	.35
Toluene, in tank cars	gal.	.25 —	.28
Toluene, in drums	gal.	.30 —	.35

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

GADSDEN—The Gadsden Clay Products Co. will construct a new power house at its plant and make other extensions and improvements. Gordon Hood is secretary and treasurer.

TROY—The Standard Chemical & Oil Co. is considering plans for the rebuilding of the portion of its plant No. 1, destroyed by fire, March 22, with loss estimated at about $75,000.

MONTGOMERY—The Sloss-Sheffield Steel Co. has tentative plans under consideration for the construction of an addition to its plant, including blast furnace with daily output approximately 250 tons.

RUSSELLVILLE—The Muscle Shoals Rock Asphalt Co., recently organized with a capital of $1,000,000, has acquired property totaling about 3,000 acres of asphalt rock lands and will build a local refining works with daily output of about 1,000 tons. C. E. Dexter, Louisville, Ky., is president.

Florida

ORLANDO—The Yowell-Drew Co. has acquired the local plant of the Orlando Pottery and has plans under way for a number of extensions and improvements. New equipment will be installed. N. P. Yowell is president.

Indiana

EVANSVILLE—The Atomized Products Corp., 6th St., has plans under way for the construction of a 2-story and basement addition, to cost about $75,000, including equipment. B. V. Cain is general manager.

ANDERSON—The International Rubber Co. of America, organized under Delaware laws with capital of $20,000,000, has acquired the local plant of the Quality Tire & Rubber Co. for a consideration of about $200,000 at a receiver's sale. The new owner will use the plant as an initial unit and will make necessary improvements. The company is said to be negotiating for the acquisition of the other plant of the Quality company, located at Elyria, O. J. D. Wiggins is president and general manager; M. D. Ganger is vice-president and superintendent.

EVANSVILLE—The Southern Indiana Gas & Electric Co. will build a large gas retort in connection with an addition to its local gas plant. Frank J. Haas is general manager.

Iowa

DAVENPORT—Fire, March 30, destroyed a portion of the plant of the Mammoth Glucose Co., with loss estimated at about $300,000, including machinery. The southwest wing of the structure was demolished.

DUBUQUE—The Globe Portland Cement Co., 416 McKnight Bldg., Minneapolis, Minn., will soon break ground for the construction of its proposed new local cement mill, comprising a number of buildings, estimated to cost about $1,500,000, including equipment. General building contracts for the work have been let. The C. L. Pillsbury Co., 1200 2nd Ave. South, Minneapolis, is engineer.

Louisiana

ALEXANDRIA—The Alexandria Oil & Refining Co. will soon commence the erection of an addition to its local oil refinery and will install equipment to double approximately the present output. H. T. Clark is president.

MONROE—C. H. Cole and associates are organizing a new company with capital of $250,000, to acquire and operate the local plant of the Monroe Cotton Oil Co. Negotiations for the purchase of the mill are being concluded and possession will be taken at an early date. The new owners plan for the installation of new machinery and will make a number of other improvements in the plant.

ST. ROSE—The Empire Oil & Gas Co., operating the former refinery of the Corson Petroleum Co., has preliminary plans under consideration for the construction of a large addition, to cost approximately $1,000,000, including equipment.

Maryland

CUMBERLAND—The Potomac Glass Co., manufacturer of tableware and glass novelties, is planning for the early occupancy of its new plant addition now nearing completion, and which has been designed to double the capacity. The extension will include a 10-pot furnace and auxiliary equipment, and represents an investment of about $100,000. It will give employment to more than 250 men. George L. Wellington is president.

BALTIMORE—The Rennous-Kleinle Division of the Pittsburgh Plate Glass Co., 3221 Frederick Ave., has revised plans under way for the construction of a 4-story and basement addition, 75 x 205 ft., estimated to cost about $50,000. Bids will soon be asked.

SALISBURY—The Standard Oil Co., Pratt and Commercial Sts., Baltimore, has acquired property on the east branch of the Wicomico River, Salisbury, as a site for a new distributing plant. Construction will soon be commenced on a number of steel tanks, pumping plant and other departments. The company has also acquired property at Cedar Ave. and 33rd St., Baltimore, 100 x 100 ft., and will use the site in connection with its local distributing plant.

Massachusetts

MARLBORO—The Dennison Mfg. Co., Framingham, Mass., manufacturer of paper products, has awarded a contract to the Aberthaw Construction Co., 27 School St., Boston, for the erection of a 4-story plant, 80 x 270 ft., on Maple St., Marlboro, estimated to cost about $500,000, with machinery. It will give employment to more than 500 operatives. Monks & Johnson, 99 Chauncey St., Boston, are architects.

Nevada

RENO—The Candelaria Mines Co. is completing plans for the construction of a new reduction plant on local site, with cyanide unit to have an initial capacity of 200 tons per day, and crushing department 400 tons daily.

New Jersey

TRENTON—The Keystone Pottery Co., New York Ave., has filed plans for the erection of a 1-story addition to its plant. The company specializes in the production of sanitary ware.

GLEN RIDGE—The Matchless Metal Polish Co. has acquired the plant of the Rare Metal Products Co., Bloomfield Ave. near Hillside Ave., which it has been occupying under lease. The plant consists of a main 3-story mill, with power plant, and will be used exclusively by the new owner. The site approximates 2½ acres of land, allowing for later proposed expansion.

New York

LOCKPORT—The A. W. Jack Corp., North Transit Road and Mill St., manufacturer of asbestos mill board and kindred products, will call for bids at once for the erection of a new plant on site adjoining its present works, to consist of a series of five buildings, brick and reinforced concrete, estimated to cost about $350,000, including machinery. Ground will be broken early in May and it is expected to have the plant ready for service by the close of the year. George F. Hardy, 309 Broadway, New York, N. Y., is engineer.

LITTLE FALLS—The Barnet Leather Co., 81 Fulton St., New York, N. Y., is completing plans and will soon take bids for the erection of an addition to its tanning plant at Little Falls, devoted for the most part to the manufacture of calf leathers. It will cost about $100,000, including equipment. Thompson & Binger, 280 Madison Ave., New York, are architects.

BROOKLYN—The Brooklyn Union Gas Co., 176 Remsen St., has completed plans for the erection of a 1-story gas-purifying house at its plant at Smith and 5th Sts.

LONG ISLAND CITY—Fire March 29 destroyed a portion of the 2-story plant of the Imperial Paint Co., 84 10th St., with loss estimated at about $50,000.

LOCKPORT—The Board of Works is planning for the installation of a new filtration plant at the waterworks, with storage reservoir, estimated to cost $360,000. A proposition to authorize James P. Wells, Cutler Bldg., Rochester, N. Y., engineer, to prepare plans is before the Board of Aldermen.

Ohio

FRANKLIN—Fire March 20 destroyed a portion of the local plant of the Vulcanite Roofing Co., manufacturer of paper composition roofing, with loss estimated at $250,000, including buildings and equipment. The company forms the Roofing Division of the Beaverboard Companies, Inc., Buffalo, N. Y., with headquarters at 2246 West 49th St., Chicago, Ill. Tentative plans for rebuilding the plant are being considered.

Pennsylvania

PITTSBURG—The Pennsylvania Chemical & Research Co., care of Loomis & Satterwaite, 410 Lloyd Bldg., architects, has awarded a contract to the Truscon Steel Co., Oliver Bldg., for the erection of a 1-story laboratory at Hays, Pa., 30 x 100 ft.

SHAMOKIN—J. E. Shipman & Son, manufacturers of fertilizer products, have commenced the erection of a new plant to replace their works recently burned.

CLEARFIELD—The Elk Tanning Co. is considering plans for the rebuilding of the portion of its plant destroyed by fire, March 28, with loss estimated at about $300,000, including equipment.

PHILADLEPHIA—The E-Z Chemical Co. has leased the 3-story building at 640-42 Rodman St. for a local plant.

WESTFIELD—The Pennsylvania Potash & Fertilizer Co. plans for the erection of a new plant on local site.

Tennessee

CONCORD—H. J. Winfrey & Sons are planning for the construction of two new kilns at their lime works, and will take bids until about May 1.

JACKSONVILLE—The Nashville Pulp & Paper Corp. will commence the erection at an early date of a number of new plant units at its works, Old Hickory Station. Other portions of the plant are now in course of construction. The entire works will consist of about eight complete operating units, estimated to cost close to $1,000,000. R. G. Cullen is engineer.

Texas

FREEPORT—The Freeport Sulphur Co. has leased the sulphur properties of the Texas Co., Houston, Tex., at Hoskins Mound, near Brazaria, Tex., and plans for the immediate development of the land. A complete surface plant will be installed and other production facilities established, estimated to cost in excess of $500,000. It is proposed to be ready for operation in about 10 months.

Virginia

HARRISONBURG—H. W. Dickey, operating the Harrisonburg Sanitary Pottery, is planning for the rebuilding of the portion of the plant, recently destroyed by fire, with loss of about $25,000.

Washington

SPOKANE—The Frantz Oil Corp., Frank Frantz, president, recently acquired by the Mutual Oil Co. of Wyoming and now operated as a subsidiary organization, has plans under way for the erection of a new oil refinery at Spokane, to have a capacity of about 1,000 bbl. per day and estimated to cost approximately 300,000, with equipment. Work will be commenced late in April.

WELLSBURG—The Eagle Glass & Mfg. Co. has awarded a contract to the Truscon Steel Co., Oliver Bldg., Pittsburgh, Pa., for the erection of three 1-story buildings at its plant, with main structure 50 x 100 ft. H. W. Paull is president.

KANAWHA CITY—Fire March 27 destroyed a portion of the local plant of the Libbey-Owens Sheet Glass Co., with loss estimated at about $200,000, including equipment. It is planned to rebuild. Headquarters of the company are in the Nicholas Bldg., Toledo, Ohio.

New Companies

THE IMPROVED OIL & REFINING CO., Okmulgee, Okla., has been incorporated with a capital of $100,000, to manufacture refined petroleum products. The incorporators are Paul M. Pope and W. B. Bahn, Oklahoma City, Okla.; and R. L. McClure, Okmulgee.

THE SCIENTIFIC CHEMICAL CO., Wilmington, Del., has been incorporated under state laws with a capital of $100,000, to manufacture chemicals and chemical byproducts. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington.

THE UNIVERSAL CHEMICAL CO., 16 Beach St., Boston, Mass., has filed notice of organization to manufacture chemicals and chemical byproducts. The company is headed by Harry Schlosberg.

THE TOMASEK TERRAZZO MOSAIC CO., 3147 West Van Buren St., Chicago, Ill., has been organized under state laws to manufacture mosaics and other fine ceramics. The incorporators are James E. Tomasek, Edward O. Degrenier and Alexander Campbell.

THE WOODLEY PETROLEUM CO., New York, N. Y., has been incorporated under Delaware laws with capital of $25,000,000, to manufacture petroleum products. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

THE SHAMROCK COTTON OIL CO., Shamrock, Tex., has been incorporated with a capital of $30,000, to manufacture oil products. The incorporators are F. A. Bailey and N. L. Carter, both of Shamrock.

THE CUBAN DOMINICAN SUGAR CO., 101 East Fayette St., Baltimore, Md., has been incorporated with a capital of 1,100,000 shares of stock, no par value, to operate a sugar refinery. The incorporators are Joseph W. Murphy, Frank J. Horan and James B. Guaragha.

THE UNITED LEATHER CORP., New York, N. Y., has been incorporated with a capital of $2,000,000, under Delaware laws, to manufacture leather products. The incorporators are Harold E. Edwards, M. C. Fargis and E. M. Pickert. The company is represented by the Corporation Trust Co. of Delaware, Dover, Del.

THE MITCHELL OIL CO. OF NEW JERSEY, Newark, N. J., has been incorporated with a capital of $50,000, to manufacture oil products. The incorporators are Theodore G. Hindenlang, Howard W. and George H. Lambert, 9 Clinton St., Newark.

THE FAIRMONT MOLDING CORP., Norfolk, Va., has been incorporated with a capital of $50,000, to manufacture metal castings. W. M. Hannan, Jr., is president, and R. B. Howton, secretary, bothh of Norfolk, Va.

THE MOTH K-L CO., Cranford, N. J., has been incorporated under Delaware laws with a capital of $1,250,000, to manufacture insecticides and other chemical products. The incorporators are P. B. Littlehall, Cranford; M. G. Reese, East Orange, N. J., and H. E. Hilty, New York, N. Y. The company is represented by the Registrar & Transfer Co., 900 Market St., Wilmington, Del.

THE AMERICAN SHALE BRICK CO., Martinsburg, W. Va., has been incorporated with a capital of $100,000, to manufacture brick and other burned clay products. The incorporators are Charles L. Magee, Washington, D. C.; James N. Dyson and F. Vernon Aler, Martinsburg. The last noted represents the company.

THE REX CHEMICAL CO., Salem, Va., has been incorporated with a capital of $1,000,000, to manufacture chemicals and chemical byproducts. The incorporators are Victor Yonce and R. B. Shelor, both of Salem.

THE IVANHOE COPPER CO., Wilmington, Del., has been incorporated under state laws with capital of $600,000, to manufacture refined copper and kindred metals. The company is represented by the corporation Service Co., Wilmington, Del.

THE DAULER OIL CO., Pittsburgh, Pa., is being organized by George B. Berger, Frank S. Delp and W. F. Hughes, to manufacture refined oil products. The company is represented by Calvert, Thompson & Wilson, 1737 Oliver Bldg., Pittsburgh.

THE INDUSTRIAL AROMATIC CO., Newark, N. J., has filed notice of organization to manufacture oil products. The company is headed by J. deSala Mendes, 201 Sherman Ave., Newark.

THE MISSOURI CLAY MINING CO., Poplar Bluffs, Mo., has been incorporated with a capital of $100,000, to operate clay properties, and manufacture burned clay products. The company is headed by John Denton, Ozark, Mo.

THE WILLIAM A. BANKS CHEMICAL CO., Pittsburgh, Pa., is being organized by Robert Carson, E. M. Haller and Carl E. Glock, Pittsburgh, to manufacture chemicals and chemical byproducts. The company is represented by J. M. Graham, 1712 Oliver Bldg., Pittsburgh. Application for a state charter will be made on April 18.

THE TOMLINSON PAINT & VARNISH CO., 2213 North Crawford Ave., Chicago, Ill., has been chartered under state laws, to manufacture paints, varnishes, oils, etc. The incorporators are Edwin W. and Charles N. Tomlinson, and William Sporleder.

THE TIGER OIL CO., Tulsa, Okla., has been incorporated under Delaware laws, with a capital of $1,000,000, to manufacture petroleum products. The incorporators are H. R. McGill, Burton Hartley and Herbert Miller, all of Tulsa. The company is represented by the United States Corporation Co., 65 Cedar St., New York, N. Y.

THE NEW NORMA CHEMICAL CO., Memphis, Tenn., has been chartered under state laws to manufacture chemicals and chemical byproducts. The incorporators are D. E. Chamberlin, Gerald A. Cotter and W. H. Englehard, all of Memphis.

THE P. J. BOUR CORP., Pittsburgh, Pa., is being organized by P. J. Bour, George H. Lepper and George H. Sherman, to manufacture heat-and slag-resisting cements and other refractory products. Application for a state charter will be made on April 17. The company is represented by Saul Schein, 1506-10 Berger Bldg., Pittsburgh.

THE POLLYANNA OIL CO., Minneapolis, Minn., has been incorporated under Delaware laws, with a capital of $400,000, to manufacture petroleum products. The incorporators are E. C. Carmen, R. G. Powell and Gordon Cain, Minneapolis. The company is represented by the Corporation Registry Co., 900 Market St., Wilmington, Del.

THE GREAT EASTERN OIL CO., 1119 Fidelity Bldg., Baltimore, Md., has been incorporated with a capital of 600 shares of stock, no par value, to manufacture oil products. The incorporators are George S. Price, George C. Hepp and Marion W. Thomas.

THE VIC RUBBER CO., New York, N. Y., has been incorporated with a capital of $20,000, to manufacture rubber products. The incorporators are S. and M. Gromet, and S. Kaplan. The company is represented by H. H. Feigin, 261 Broadway.

THE EVANSTON GLASS CO., Chicago, Ill., has been incorporated with a capital of $10,000, to manufacture glass specialties. The incorporators are Ralph R. Swarthout, William J. Ross and Ralph D. Matteson, 30 North Dearborn St., Chicago.

THE MICHIGAMUA OIL CO., Ann Arbor, Mich., has been incorporated with a capital of $25,000, to manufacture refined petroleum and other oil products. The incorporators are A. M. and John J. Cox, and R. F. Weslie, all of Ann Arbor.

JOHANESON, WALES & SPARKE, INC., New York, has been incorporated with a capital of $100,000, to manufacture pulp and paper products. The incorporators are W. M. Wilson, A. M. Hanson and G. S. Webster, Jr. The company is represented by G. M. Spencer, 120 Broadway, New York.

THE COSMOPOLITAN OIL CO., Indianapolis, Ind., has been incorporated with a capital of $500,000, under Delaware laws, to manufacture petroleum products. The incorporators are Everett C. Arnold, Asher Buck and Frank A. Moore, all of Indianapolis. The company is represented by the United States Corporation Co., 65 Cedar St., New York, N. Y.

THE MOORE BRASS WORKS, Wilmington, Del., has been incorporated under state laws, with capital of $50,000, to manufacture brass, bronze and kindred products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del.

THE ARLINGTON ANILINE WORKS, INC., Peabody, Mass., has been incorporated with a capital of $20,000, to manufacture colors, dyes and affiliated products. Arthur A. Krivian is president; and Bernard Lander, Roxbury, Mass., treasurer.

THE U-MIX-IT CHEMICAL CO., 11 Winthrop St., Hartford, Conn., has filed notice of organization to manufacture chemicals and chemical compounds. M. H. Miller heads the company.

Industrial Notes

THE ORTON & STEINBRENNER CO., of Chicago, Ill., and Huntington, Ind., manufacturer of locomotive cranes, clam-shell and orange-peel buckets and coal crushers, has made arrangements with J. Ross Bates, formerly connected with the Wonham Bates & Goode Trading Corp. of N. Y. and Boston, to represent it in the New England States and New York City. Mr. Bates has offices at 136 Liberty St., New York City, and 128 School St., Watertown, Mass.

THE UEHLING INSTRUMENT CO., manufacturer of CO_2 recorders and other fuel economy equipment, will be located at its factory, 473 Getty Ave., Paterson, N. J., instead of at its former address, 71 Broadway, New York City.

SANDVIK STEEL, INC., announces the consolidation of its general steel and steel belt conveyor departments in Suite 2001, Woolworth Bldg., New York City, with the following executive officers: W. D. Thomas, president and general manager; Anders Johnson, vice-president; Gurrick M. Spencer, secretary, and Harry Carlson, sales manager.

THE WHITLOCK COIL PIPE CO., Hartford, Conn., announces that in addition to its regular agents and representatives it has recently obtained the services of George D. B. Van Tassel, superheater expert, of Detroit, Mich., who will represent the company's interests in Detroit and vicinity.

THE CARBORUNDUM CO., Niagara Falls, N. Y., announces the appointment of Harry Fowler as district sales manager of the Cincinnati territory, to succeed Charles R. Cox. Mr. Cox has been transferred to the main office at Niagara Falls to take up new duties on sales statistics.

THE MCCLAVE-BROOKS CO. has appointed the Mahler Machinery & Supply Co., 1445 Syndicate Trust Bldg., St. Louis, Mo., as its sales representative for that district for McClave combustion systems, including stokers, grates, steam blowers, boiler fronts, etc.

THE CELITE PRODUCTS CO., Chicago, Ill., announces that during the last 3 months there have been a number of changes in its sales organization, including the establishment of branch offices in Boston, Buffalo, Cincinnati and Minneapolis. F. W. Emerson is in charge of the Boston office, W. D. VanArnam in the Buffalo territory, L. M. Lindsey in the Cincinnati office and E. R. LaBelle at Minneapolis. A change has been made in the New Orleans office, and J. C. Etheredge is now district manager for that territory.

THE OLIVER CONTINUOUS FILTER CO., 33 West 42nd St., New York, will demonstrate at its New York laboratory the application of the Oliver continuous filter to pulp washing during the convention in New York of the pulp and paper industry the week of April 10. All pulp and paper men will be welcome at this demonstration.

THE COMBUSTION ENGINEERING CORP., New York, announces the opening of a new branch office at 1137 Guardian Bldg., Cleveland, O., which will be in charge of Frank Henderson, who has been associated with several of the prominent stoker companies in that territory.

THE ELECTRIC FURNACE CO. has moved its general and sales offices from Alliance, O., to Salem, O. By this action all departments of the company will be consolidated at its works, Wilson St. and Pennsylvania Railroad, Salem, O.

THE CHAIN BELT CO., Milwaukee, Wis., has announced the appointment of G. F. Sherratt as manager of the Pittsburgh office in the Union Arcade Bldg. Mr. Sherratt will be in charge of all the company's chain and engineering business in the Pittsburgh territory and is equipped to render

engineering service on power transmitting and material handling problems. The Chain Belt Co. specializes on chain and material handling equipment for all industries. The products of the company are manufactured under the trade name of "Rex." The Ward Equipment Co. of Pittsburgh will continue to handle the complete line of Rex concrete mixers and pavers, and the United Equipment Co. the Rex traveling water screens.

W. E. MEGRAW, safety director of the H. H. Robertson Co.'s plant at Ambridge, Pa., was handed a fac-simile of the Rice Safety Award bronze tablet, because of the total elimination of accidents in 1921, at the recent fourth annual banquet of the Western Pennsylvania division of the National Safety Council. Mr. Megraw in a brief talk accepted the award on behalf of the 124 employees who had achieved a record heretofore believed impossible in accident prevention work. This is particularly interesting because in addition to the usual industrial hazards, the men are constantly unloading and handling steel sheets, coating them with asphaltic compounds heated to from 300 to 400 deg., often under severe fume conditions, moving the sheets and the finished product from place to place, and at times working on lines through which hot oils are piped.

THE WESTINGHOUSE ELECTRIC & MFG. CO. announces that owing to increasing activity in the power and railway divisions of the Pittsburgh office the two divisions will be separated. Burton Steveson, who has been manager of both divisions, will continue as manager of the power division and F. G. Hickling has been appointed manager of the railway division.

THE BUTTERWORTH-JUDSON CORP., manufacturer of acids, intermediates and dyestuffs, has canceled its contract with L. M. Bowes, under which Mr. Bowes, doing business as the Standard Color Co., was sole seller of Butterworth-Judson dye products. It is the intention of the Butterworth Judson Corp. to market all of its products through its own selling force. After April 8 the sales offices of the corporation will be located at 30 Church St., New York City. The expansion of the sales department necessitated this changing to larger quarters.

THE WESTON ELECTRICAL INSTRUMENT CO., of Newark, N. J., announces the appointment of the following sales representatives: Shiefer Electric Co., Inc., with offices at Rochester, Buffalo and Syracuse, N. Y., for upper New York State and Erie, Pa.; L. D. Joralemon, Otis Bldg., Philadelphia, Pa., for Pennsylvania, Delaware, Maryland and the District of Columbia, and the Warren C. Graham Co., Carondelet Bldg., New Orleans, La., for Louisiana, Mississippi and lower Alabama.

Capital Increases, Etc.

THE MADISON GLUE MFG. CO., 97 Beekman St., New York, N. Y., has filed notice of increase in capital from $10,000 to $100,000.

THE MAMER BRICK CO., Benton Harbor, Mich., has filed notice of increase in capital from $60,000 to $160,000, at the same time changing its name to the Mamer Co.

THE MANATI SUGAR CO., 112 Wall St., New York, N. Y., is disposing of a bond issue of $8,000,000, the proceeds to be used for general financing, refinery operations, extensions, etc. Regino Truffin is president.

THE STANDARD CLAY CO., a Delaware corporation, has filed notice of organization to operate at Brazil, Ind., with capital of $300,000, to manufacture brick, pipe and other burned clay products. The company is represented by Albert F. Price, Brazil.

THE COLUMBIAN BRONZE CORP., Freeport, L. I., has filed notice of increase in capital from $450,000 to $1,250,000.

THE BINGHAMTON GLASS CO., Binghamton, N. Y., has filed notice of increase in capital from $60,000 to $150,000.

THE UNION BAG & PAPER CORP., Woolworth Bldg., New York, N. Y., with plants at Hudson Falls, N. Y., and other points, is arranging for a bond issue of $15,000,000, of which about $7,000,000 will be offered for sale at an early date.

THE NOCO OIL PRODUCTS CO., St. Louis, Mo., has been organized to take over and consolidate Cleage & Co., St. Louis, Mo., and the Noco Petroleum Co., Kansas City, Mo., and operate oil refineries. Thomas D. Cleage heads the new organization.

THE UNION OIL ASSOCIATION, Los Angeles, Cal., has filed notice of incorporation with capital of $30,000,000, to take over the properties of the Union Oil Co. of Cal., including refineries, pipe lines, etc.

Industrial Developments

RUBBER—The Thermoid Rubber Co., Trenton, N. J., has adopted a capacity day-time operating schedule at its plant. It is planned to inaugurate a night shift at an early date.

The Goodyear Tire & Rubber Co., Akron, O., has increased production from 20,000 to 22,000 tires a day at its local plant, as compared with an output of about 13,000 tires daily during last November. A large increased working force is being employed.

The Goodyear Rubber Co., Middletown, Conn., has increased operations from 4 to 5 days a week at its local plant, giving employment to more than 250 persons.

The General Tire & Rubber Co., Akron, O., is increasing production at its plant, with tire department running at close to regular capacity. The first quarter of the present year has produced a 65 per cent increase in sales as compared with the corresponding period of a year ago.

CERAMIC—Potteries in the East Liverpool, O., district are increasing operations, with bulk production of the 30 plants devoted to general ware and kindred products averaging in excess of 86 per cent of normal at the present time.

The St. Joe Brick Works, Slidell, La., operated by M. P. and C. W. Schneider, have adopted a full-time production schedule on a basis of 40,000 bricks per day, giving employment to more than 100 men.

OIL—The Sapulpa Refining Co., Sapulpa, Okla., has arranged for the immediate resumption of production at its local refinery, following a shut-down for a number of weeks. The plant has a rated output of 5,500 bbl. per day.

PAPER—The S. Y. Beach Paper Co., Seymour, Conn., has resumed operation at its local mill, with employment of about 80 men, following a shut-down for more than a year. The company will make a number of improvements in the plant, with the installation of additional equipment for increased output.

IRON AND STEEL—The Tennessee Coal, Iron & Railroad Co., Birmingham, Ala., has placed operations on a capacity basis in the open-hearth department at its Ensley, Ala., works. During the past month the company has blown in three blast furnaces, all devoted to basic iron. Record production is being developed in the line of ingots and billets.

Two of the largest works of the Carnegie Steel Co., at Homestead and Duquesne, Pa., are now operating in all departments, following the blowing in of blast furnaces and resumption at the 72-in. and 110-in. mills. The works have been idle, in part, for some months past. The company will soon blow in the furnace No. 1, at its New Castle, Pa., plant, the only unit now idle at the mill; this will place the works on a 100 per cent basis for the first time in more than a year. Operations have been resumed at the mills at the Mingo Junction, O., plant of the company, with addition of about 100 men to the working force. This plant will soon go on a 100 per cent basis, with the employment of approximately 200 more men. Another blast furnace has been blown in at the Edgar Thomson works of the company at Braddock, Pa., making 7 out of 11 units in service at the mill.

The Brier Hill Steel Co., Youngstown, O., is arranging to blow in another stack during the present month.

The Republic Steel Co., Youngstown, O., is operating at four of the six finishing mills at the plant, and plans to increase production at an early date.

The steel plate mills in the Pittsburgh, Pa., district are now operating in excess of 80 per cent of capacity. Based on pre-war figures, this would be greater than 100 per cent of normal plant output.

The Sloss-Sheffield Steel Co., Birmingham, Ala., is planning for an early increase in production at its North Birmingham plant, giving employment to a number of additional men. Steady production is being maintained at the byproduct coke-oven plant of the company in the North Birmingham district.

The Midvale Steel Co. is planning for the immediate blowing in of one of the blast furnaces at its Coatesville, Pa., plant. The stack has been idle since last November.

TIN PLATE—The American Sheet & Tin Plate Co. has resumed operations at the four remaining mills at its Guernsey works, near Cambridge, O., developing full production for the first time since last November. At the Elwood, Ind., plant, the company has started two more double mills in operation, bringing the works to 90 per cent of capacity.

COKE—The H. C. Frick Coke Co. is arranging for the early resumption of operations at its Whitney plant in the Scottsdale, Pa., district, following an idle period of 13 months. A total of 250 ovens will be lighted for initial service. The company has added 750 ovens to the active list at the Uniontown, Pa., works.

Coming Meetings and Events

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Baltimore, April 27, 28 and 29, 1922. Headquarters will be at the Emerson Hotel.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Rochester, N. Y., during the week of June 5, 1922. Meetings will be held in the spring instead of in the fall as heretofore.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its summer meeting at Niagara Falls, Canada, June 19 to 22. Headquarters will be at the Clifton Hotel.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its nineteenth annual meeting at Bigwin Inn, Bigwin Island, in the Lake of Bays district, Ontario, Canada, on June 21, 22 and 23.

AMERICAN OIL CHEMISTS' SOCIETY will hold its annual meeting at the Grunewald Hotel, New Orleans, La., May 8 and 9.

AMERICAN SOCIETY FOR STEEL TREATING will hold a sectional meeting at the Bureau of Mines auditorium, Pittsburgh, Pa., on May 25 and 26. The International Steel Exposition and Convention of the society will be held in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-fifth annual meeting June 26 to July 1, at Atlantic City, N. J. Headquarters will be at the Chalfonte-Haddon Hall Hotel.

AMERICAN WELDING SOCIETY will hold its annual meeting April 26-29 at the Engineering Societies Building, New York City.

CANADIAN INSTITUTE OF CHEMISTRY and the SOCIETY OF CHEMICAL INDUSTRY will hold their annual meetings in Ottawa May 15-17.

CERAMIC SOCIETY (London) is to have a foreign trip to Sweden and Denmark from May 27 to June 10.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY will hold a meeting at Lyons, France, June 27 to 30.

IRON AND STEEL INSTITUTE (British) will hold its annual meeting on May 4 and 5 at the House of the Institution of Civil Engineers, Great George St., S. W., 1, London.

NATIONAL ASSOCIATION OF PURCHASING AGENTS EXPOSITION (the "Informashow") will be held in connection with the seventh annual convention of the association at Exposition Park, Rochester, N. Y., May 15 to 22.

NATIONAL COAL ASSOCIATION will hold its annual meeting at Congress Hall, Chicago, May 24-25.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (EIGHTH) will be held in New York Sept. 11-16.

NATIONAL FERTILIZER ASSOCIATION will hold its twenty-ninth annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 12.

NEW JERSEY CHEMICAL SOCIETY will meet at Stetters Restaurant, 842 Broad St., Newark, N. J., the third Monday of April, instead of the second Monday as usual.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY and the AMERICAN PULP AND PAPER ASSOCIATION are holding annual meetings at the Waldorf-Astoria, New York, this week.

The following meetings are scheduled to be held in Rumford Hall, the Chemists Club, New York: April 21—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting; May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting; June 9—American Chemical Society, regular meeting.

A Development Committee For the American Chemical Society

AT ITS meeting in Birmingham 2 weeks ago the American Chemical Society took official action which, if followed to a logical conclusion, will have a profound bearing on the future development of the organization. By vote of the Council, the president is to appoint a committee of seven to consider the Society's aims and purposes, its present activities, its needs, its service to members and its general efficiency in accomplishing the objects to which it is dedicated.

This is a timely step. The A.C.S. is the last of the great national engineering and scientific bodies to take stock of its activities and determine by a careful survey how closely it is in harmony with the spirit of the times. The need is even greater because the Society has grown rapidly in numbers; and expression of the views of the membership and participation in Society functions have become increasingly difficult. In fact the bulk of the membership is probably inarticulate on most of the Society's problems. This is inevitable in some degree, but the constant effort should be to improve a society's machinery to make it more satisfactory and efficient.

What are some of the things to be considered by the development committee of the A.C.S.? First, there is the problem common to all our national bodies—a direct consequence of the length and breadth of our land—of regional representation in the directorate of the Society, based on the geographical distribution of the membership. Another problem arising from the same source is how to afford a scattered membership opportunity to participate in conventions and sectional gatherings.

A possible solution lies in discontinuing one of the two general meetings per year, either spring or fall, and substituting therefor an appropriate number of intersectional meetings in different parts of the country. This plan, combined with a generous distribution of annual meetings, would encourage participation by a larger number of members. Further, the papers for the annual meetings could then be more carefully scrutinized before acceptance, and the quality of the programs raised accordingly.

Another subject for investigation relates to grades of membership. Who is a chemist? Everyone who belongs to the A.C.S.? By no means! And yet by appropriate regulation it would be easily possible to grade membership in the A.C.S. so that the term "member" or "fellow" would be a guarantee that rigid qualifications had been complied with. No one could feel hurt if he were unable to meet the requirements, but he could take professional pride if he were able to measure up to the standard. And it would help to answer the question, "Who is a chemist?"

Other matters for consideration by the committee will arise out of the publishing activities of the society. The A.C.S. is in the publishing business in a large way. Is it satisfactory to the members? How is it managed? What does it cost? What changes or improvements are desired, if possible? The Society's finances undoubtedly will also come under the scrutiny of the committee and the membership in the interest of effecting possible economies. In short, every activity and policy of the Society will be laid open to friendly criticism if the investigation is conducted as thoroughly in the A.C.S. as it has been in the other national bodies.

It is the intention to complete the investigation within 6 months and to have the committee report at the Pittsburgh meeting next fall. This will necessitate active work in getting the views of local sections on the various questions, possibly holding open hearings in some important centers, so that recommendations can be formulated within the allotted time.

In our judgment a vast amount of good can come to the Society as a result of this action. Professional bodies, like business companies, need occasional overhauling. They get into ruts and lose the spirit of progress. Above all they fail sometimes to keep in touch with their members until dissension arises with all its undesirable and unfortunate consequences. Much of the success of the investigation will depend on the composition of the committee—a matter to which President SMITH undoubtedly will give the most careful attention. The rest will depend on the spirit in which the committee works and the extent to which the membership co-operates.

The Senate Tariff Bill

IN ANOTHER part of this issue we publish a brief review of the salient features of the Senate tariff bill. The Finance Committee's revision of the measure passed by the House last July contains many provisions of vital importance to our chemical industries. Outstanding among these is the temporary extension of the embargo on dyes and synthetic organic chemicals—an action viewed with satisfaction only by those who have been most pessimistic of the legislative situation.

Continuing the dye and chemical control act of the emergency tariff for 1 year (or 2 at the discretion of the President) doubtless offers encouragement for the resumption of manufacturing activities, but it is questionable if it is sufficient to attract the new capital necessary to round out the complete development of the dye industry. Manufacturers in a position to know tell us that in the average dye plant a complete turnover of equipment and process is necessary within a period of about 10 years. To cope with such a situation and at the same time to continue the development and exploration into new fields requires definite assurance that this work will not be wiped out in 1 or 2 years.

The dye embargo will probably meet some opposi-

tion in the Senate, but it is hoped that the favorable light thrown on the industry during the recent investigation of the Senate Judiciary Committee will react in its favor. The attitude of the farm bloc is not yet known, but announcement has recently been made that the agrarians have chosen Senator NICHOLSON of Colorado to lead their attack on the chemical and metal schedules. It will be recalled, with no little apprehension perhaps, that Senator NICHOLSON'S predecessor was the "doubting Thomas" whose tactics succeeded in defeating the Longworth bill in 1920.

Not unwelcome among the other changes in the chemical schedule is the substitution of specific duties for about thirty ad valorem rates. These are thereby removed from the field of controversy regarding the method of valuation which will be carried in the final draft of the law. The wide discretionary powers given to the President add to the uncertainty of the tariff, but if wisely used may offer a workable solution to the problems arising from changing economic conditions.

In analyzing the many provisions of the chemical schedule we have thought it desirable to offer a tabular comparison with the rates in the House bill and in the existing tariff law. The preparation of such a table entails a number of difficulties. For example, the basis for assessing ad valorem duties in the Senate bill is the same as in the act of 1913—namely, foreign market value—but it is not the American valuation plan used in the Fordney bill. Furthermore, many of the paragraphs show slight changes in phraseology, which must yet be interpreted by the customs authorities and therefore render comparisons difficult and hazardous. For these and many other reasons we are convinced that the bill itself deserves the careful study of all who are directly affected by its provisions.

Raising the Standard Of University Instruction

APPARENTLY, a certain section of the readers of technical periodicals feel that the editor knows everything—or at least knows somebody who can tell them what he doesn't know. Of course, this is a very flattering compliment, and one which tickles even a dormant vanity.

So the editor gladly tells SMITH the composition of magnalite, and obtains for JONES a few facts about the manufacture of tin oxide, or sends BROWN a list of competent chemists, with a gentle reminder that technical advice should come from consultants.

Once in a while a request arrives which excites some speculation—not so much because of the information it seeks as a wonder about just what is going on in the head of the correspondent. For instance:

"Could you send me some matter on the subject of steel, as an alloy, chiefly from the mechanical and structural viewpoint? I am to give a lecture on this subject at —— University shortly, and would be very grateful for any slight assistance. The matter need not be very extensive, as my time is limited."

Now the university which is to hear the lecture is no mean institution, and the lecturer is a man who assuredly is expert in a certain branch of philosophy. But what imp has given both the university and the lecturer the idea that he is competent to instruct anyone in "steel as an alloy," even in a limited time? Dozens of engineers who know something about steel as an alloy for machines and structures live within an hour's travel of this university, thirsty for knowledge. It would be curious to know if one of the best of them would accept a similar invitation to expound the creeds of Homoousians and Homoiousians, and then write to the editor of *Christian Science Monitor* for data.

Aluminum and Magnesium

IT IS tempting to start this essay with some hackneyed phrases like "It never rains but it pours." New alloys are being described in great number. Particularly alloys of the light metals, alloys devised and studied by the more progressive establishments which find themselves able to produce war-time supplies of aluminum, magnesium or silicon, and only disarmament conferences in the offing! If widespread popular use of these now relatively scarce metals should follow their development for army and navy, the history of heat-treated alloy steels for projectiles and armor plate would only repeat itself.

The development of uses for aluminum is well known. Shortly after its discovery it was hailed as "the coming metal," but these prophecies have yet to be fulfilled. Its white color and the fact that it needed no enamel to keep it from rusting have given it a great vogue for household utensils. Large quantities of castings are also used where lightness, durability and attractive color are desirable. It has even become a very serious competitor to copper for high-tension transmission lines—for equal duty the supporting towers can be set so much further apart and the transportation charges be so much reduced that the larger cost of aluminum per pound is often more than wiped out.

But it waited for the discovery of some method to harden and strengthen aluminum before it could be used as a structural alloy; this has been done in the alloy "duralumin" and in the new "A," "E" and "Y" alloys developed by the English during the war. Even yet such structural uses have been confined to aircraft, and perhaps will largely remain so until engineers have developed a new designing technic which will enable them to make members combining strength and lightness, the dual advantages, to a high degree and without wasting much metal. Furthermore the cost of the principal metal, aluminum, must be reduced from its present 20 cents per pound before it can successfully compete with expensive alloy steels, two or three times as strong, even if three times as heavy.

Meantime, here comes magnesium—an essential component, although in small percentages, of the hardened aluminums. It in turn is 40 per cent lighter than aluminum, and if sufficiently pure, is apparently no more susceptible to corrosion. Its price is still high, ranging about $1 per pound, but this doubtless could be considerably reduced if any large tonnage were absorbed by industry. Magnesium also is the basis of a series of well-advertised alloys called "Electron," originated in Germany, and of Mg:Al alloys developed in this country.

It needs little imagination to convince one that the surface of this metallurgical field has only been scratched. The possibilities are almost limitless. It will be developed by many men in many different places, but what they find cannot help but be of interest to any engineer who is interested in making some new or old engine serve mankind less wastefully—that is to say, to all real engineers.

A Record in Rail Production

PRODUCTION of rails 100 lb. and over per yard in 1921 was the greatest in the history of the rail industry, the output being 849,566 tons, the heaviest production of such sections previously having been 766,851 tons, in 1916. It has been more or less customary for many years past to speak of there being a "controversy" between the rail producers and the railroads, but the word is not altogether fitting. There has been a difference of aim. The railroads wanted a higher quality of rail, with little extra cost over the base price, while the rail mills favored the using of heavier sections. It would appear from the statistics of production that the rail mills have been making progress in having their contention put into practice, for the ratio of rails 100 lb. and over to rails 85 lb. and over but under 100 lb. has been steadily increasing. The 1921 production was as follows, in gross tons:

Under 50 lb.	211,568
50 to 84 lb.	214,936
85 to 99 lb.	902,748
100 lb. and over	849,566
Total	2,178,818

The total production of rails in 1921 was small. Since 1898 there have been only 2 years, 1908 and 1914, with lighter production. The record high production was made in 1906, with 3,977,887 tons. Statistics of rail production, of course, furnish no key to the manner in which track is being maintained. In 1887 and nearby years there was much building of new railroad, with heavy rail production, as well as imports. In 1906 and nearby years there was much laying of secondary track, together with particularly great replacement because old and light section rails were being destroyed rapidly by the heavier rolling stock recently introduced.

Even at the present time there is some rail wear, necessitating replacement, that will proceed more slowly in future, through rails being replaced by heavier sections. If the rails ever catch up with the rolling stock, by improvement in quality and increase in section, annual replacement requirements of the railroads will represent a relatively unimportant portion of the total steel output of the country. It is recognized, of course, that as the section is increased the tonnage required to lay a given length of track is correspondingly increased.

The industrial use of rails has been increasing steadily with the growth of industrial operations, or even more rapidly. In 1913 the production of rails 45 lb. and lighter was 470,405 tons, whereas in 1920 the production was 489,043 tons, an 81 per cent increase, while for 1921 production, naturally enough, dropped to 211,568 tons. The proportion of light or industrial rails to rails required by the regular steam roads has greatly increased.

The bessemer rail has practically disappeared. In 1907 production was 13 tons bessemer to 1 ton open-hearth. In 1911 open-hearth passed bessemer. In 1921 there was 36 tons of open-hearth to 1 ton of bessemer. In 1912-13 a total of about 6,000 tons of electric rails was produced, for experimental purposes, while there has been practically no such production since then. The alloy-treated rails, which ran about 150,000 tons in both 1911 and 1912, have almost disappeared. Doubtless there is a connection between these facts and the increased vogue of rails 100 lb. and over in section.

The Spring Meeting In Birmingham

BIRMINGHAM is a considerable distance away from most other places—except Shelby County, Alabama, where the rigors of the Volstead act are modified with "corn." When the Alabama Section urged the American Chemical Society to be its guest for the 1922 spring meeting the state was full of chemists, and Muscle Shoals, which is a certain Irish twist in the Tennessee River, was getting ready to do something, and there were any number of willing hands there to help things along. But hard times can make great changes, and the curious illusion that qualifies American business in chemistry has also spread over Alabama. There, just as with us here in the North, merchants who have "bought into" chemistry regard research and scientific control as the first luxuries which, under pressure of hard times, a corporation should rid itself of. So there were very few Alabama chemists available at the time of the meeting, although those few did yeoman's service in looking out for the three hundred and fifty-odd registrants.

The effect of such a meeting on the city of Birmingham and environs would be hard to tell. Probably it is slight. But the enthusiasm of the men at the meeting was very great. They get closer acquainted when there are not so many, and the discussions are more informal and intimate. We doubt if the Educational Section has ever had so illuminating a meeting. This was in part because Dr. SMITH presided, and his presence is always a guaranty of the best kind of company. Then again, the subjects were well chosen, and the participants felt themselves pretty well acquainted.

Very important was the symposium on distillation which opened the meetings of the Division of Industrial and Engineering Chemistry. Organic chemistry has grown into a division of importance. It was always numerically rich in papers, but in later years some of the papers have proved to be very interesting. The Petroleum Section, soon to be dignified as a Division of the Society, maintained the high standards set in its two previous meetings at Rochester and New York. Rubber, cellulose, physical and inorganic, sugar, dye, water—in fact all the branches of chemistry represented at the divisional and sectional meetings—report encouraging progress and many noteworthy contributions.

H. G. Wells on Modern Alchemy

YOU can usually find something of interest in H. G. WELLS' books if you persevere and read far enough! After writing about half a million words on History, Mr. WELLS freshens up—possibly after a cheering session at tea and muffins, and jots down the following thoughts, only too true:

"As scientific men tell us continually, and as 'practical' men still refuse to learn, it is only when knowledge is sought for her own sake that she gives rich and unexpected gifts in any abundance to her servants. The world of today is still much more disposed to spend money on technical research than on pure science. Half the men in our scientific laboratories still dream of patents and secret processes. We live today largely in the age of alchemists, for all our sneers at their memory. The 'business man' of today still thinks of research as a sort of alchemy."

ENSLEY BLAST FURNACES, TENNESSEE COAL, IRON & RAILROAD CO.

Birmingham Meeting, American Chemical Society

Report of the Sixty-third Meeting, April 3-7, 1922—Council Meeting—Addresses at General Sessions—Abstracts of Papers Presented at the Industrial, Physical and Inorganic, Rubber, Sugar, Dye and Water Divisions and at Educational, Historic, Cellulose and Petroleum Sections

BIRMINGHAM, Iron City of the South, threw wide her gates on April 3 to 7 for the convening of the sixty-third meeting of the American Chemical Society. In point of attendance the spring meeting fell short of most of the Society's recent gatherings, for less than 400 members were registered, but this loss in numbers was more than compensated by the better opportunities for developing acquaintanceships and stimulating good fellowship. Southern hospitality was seen at its best. The local committees, the members of the Alabama Section, the industries and the generous-hearted citizens of the Birmingham district did much to make the excursion into the Southland one of the most memorable in the history of the Society.

The Council Meeting

The Council met at 4 p.m. at the Southern Club, with President Smith in the chair. He believed the past year had been one of progress in building up a better understanding of what chemistry means in the public mind. There is, however, still a great deal to be done and he urged on members of the Society the need constantly to expound the relations of chemistry to progress.

The Society has had an annual deficit to meet for 3 years past, so that the directors, in order to avoid loading it with debt, had planned for certain restrictions in expenditure. These consisted in refusing the additional quotas asked for and needed by the editors of *Abstracts* and the *Journal*, in cutting down the appropriation for the *Industrial Journal*, and in omitting the publication of the formula index. They did this with great regret, but sound financing made it necessary to limit the budget to their means. President Smith then called upon Secretary Parsons to read a letter from President F. P. Garvan of the Chemical Foundation in which he advised that that corporation would make good any deficit of the Society up to $25,000, in order to avoid the retrenchments decided upon, to the end that the progress of chemistry in America may not be inhibited for lack of proper information. The thanks of the Society were voted to the Foundation, to President Garvan, and also to Messrs. Parsons and Howe for negotiating the gift.

The Priestley committee made its report and asked to be discharged. A portrait has been provided and funds for a medal are in hand. President Smith, as chairman of the committee, showed a replica of the medal in bronze, and we take pleasure in saying that it was designed by an artist, and that the die provides for a medallion which is beautiful in appearance. This is a consummation devoutly to be wished, inasmuch as other greatly sought prizes in chemistry are nothing more than sculptured whisker exhibits in gold with names in raised letters. The Priestley medal is to be given once in 3 years for distinguished services in chemistry, and the committee of award is to consist of the president, the last past president, the secretary and the treasurer of the Society, and the editors of its journals. Dr. Smith was thanked for his splendid work as chairman of the committee.

Note was made of the passage of the patent bill, and the Society was congratulated on the fact.

The charges brought against American chemical industry have been well threshed out before an investigating committee in Washington, and the industry completely vindicated.

The scientific monographs are a complete success, and the technological monographs are coming along with equal promise of merit. The outlook for these works, both in pure science and in technology, is very favorable.

The deaths of Giacomo Ciamician, honorary member, and of Charles Baskerville were duly recorded and proper resolutions were spread upon the minutes.

It was voted that the Council of the Society urge the publishers of chemical books to adopt a uniform practice of printing the date of the writing or revision of every work issued. For lack of such regularity questions of priority often are held in abeyance.

The Cellulose and Petroleum Sections asked to be made regular divisions of the Society, and it was voted that they formulate bylaws and submit these for approval at the Pittsburgh meeting in September.

In order to establish regularity in the organization of divisions it was voted that 3 years shall elapse after the formation of a Section before it may become a Division.

New local sections were authorized at the Hawaiian Islands and at Sacramento, Cal., and, subject to the waiver of the Pittsburgh Section, one for northern West Virginia at Morgantown was authorized.

Next Spring Meeting in New Haven

The invitation of the New Haven Section and the Corporation of Yale University to meet at New Haven in the spring of 1923 was accepted.

Although it may not be voted on more than 1 year in advance, Dr. Smith advised that Philadelphia was planning for a great sesquicentennial exposition in 1926, and that the Philadelphia Section was urgent in the hope that the Society would meet there at that time.

Prof. William McPherson was elected director to succeed Major H. E. Howe, who, on assuming editorship of the *Industrial Journal*, became ex-officio a member of the board.

The felicitations of the Council were extended to Prof. Henry Clay White on the completion of his 50 years of service at the University of Georgia.

It was voted that the Council bear in mind that when eminent contributions are made for research or to further the advancement of chemistry, they be duly acknowledged and recorded at its meetings. The munificence of George F. Baker in building the laboratory at Cornell was a case in point.

In regard to the selection of alternates for local councilors it was ordered that the manner of selection be left to the respective Sections, but that individual councilors shall not have the power to name their own proxies.

Beginning Jan. 1, 1923, the name of the *Journal of Industrial and Engineering Chemistry* is to be changed to *Industrial and Engineering Chemistry.*

In order to consider lines of activity and measures of reconstruction that may be desirable for the Society, including a possible distinction between professional and non-professional members, it was voted that the president appoint a committee of seven to report at the Pittsburgh meeting.

It was also voted that the intersectional meetings be encouraged and that the Society approve of them.

The meeting concluded, after a dinner tendered by the Alabama Section, with reports of the various committees. In regard to maintaining an employment bureau, the sense of the meeting was that, while the Society should not undertake it, the maintenance of such a bureau by the Chemists Club or by a separate corporation be encouraged.

The General Meetings

The first general meeting was opened in the ballroom of Hotel Tutwiler on Tuesday at 10 a.m. by J. F. Carle, chairman of the local executive committee. After expressing the pleasure of the local section in having the Society meet with them, Mr. Carle introduced Nathan L. Miller, Lieutenant Governor of Alabama, who welcomed the visitors in behalf of his state. He spoke of the natural resources of Alabama which could not have been developed without the aid of the chemical profession. In referring to the water-power possibilities at Muscle Shoals recently brought to the attention of the entire country, Governor Miller said: "Whether the Ford offer is accepted or rejected, one thing must be said to his credit, and that is that by his offer he has saved this wonderful development from the junk pile. Wherever cheap power is, there is manufacturing and where there is manufacturing a great field is offered for the chemist."

W. E. Dickson, City Commissioner, was next introduced by Mr. Carle, and extended the welcome of the city of Birmingham in behalf of the municipal government. President Smith thanked the distinguished hosts in the name of the American Chemical Society, and continuing in his characteristic and delightful manner, he reviewed chemistry's recent contributions to the health, happiness and prosperity of the country. Deprecating the strife which has grown up recently between the so-called "pure" and "impure" branches of science, Dr. Smith urged a united effort in demonstrating the relation of chemistry to the welfare of the general public.

A resolution of respect to the memory of Prof. Charles Baskerville was read by Ellwood Hendrick and unanimously approved by the assembly. Similar resolutions were introduced by Prof. W. A. Noyes in observance of the death of the following eminent contributors to the science of chemistry: Giacomo Ciamician of Bologna, Italy, Adolph von Bayer of Bavaria, and Emil Fischer of Berlin.

Development of Forest Product Industries in the South

Problems confronting the forest product industries of the South were outlined in a comprehensive manner by Carlile P. Winslow, director, Forest Products Laboratory, Madison, Wis.

Enormous original timber resources in this part of the country have been developed in the past 30 years to an extent which has given direct support to from 30 to 75 per cent of the working population of the different states. However, the peak of production has been passed and a decrease to less than half the present output may be expected within the next 15 or 20 years. Since conditions in the South are more favorable to the rapid and cheap growth of timber than in any other part of the United States, immediate reforestation should relieve the situation and prevent the development of a crisis.

The practical solution to the future timber supply lies largely in definitely showing that the growing of timber is profitable. This can be accomplished to a large degree by well-directed and progressive research to determine how to utilize existing wastes and how to produce at a profit the products and byproducts existing and available in the raw material. Mr. Winslow devoted a major part of his paper to the possibilities for development in naval stores, turpentine and rosin production by steam distillation and extraction from chips, destructive distillation of hard and soft woods, newsprint paper from resinous woods, ethyl alcohol from wood waste, hydrolyzed sawdust for cattle feed, wood preservation. The elimination of waste by the use of dimension stock cutting in the secondary wood-using industries and by careful use of wood for boxes and containers was also emphasized.

Industrial Development of the South

William H. Stone, Associate Editor, *Manufacturers Record*, presented an inspiring address on "The Remarkable Development of the South and Its Relation to the American Chemical Industry." He illustrated the progress of the South since 1880 by comparing it with what the South was accomplishing prior to 1860 and what conditions were for 20 years preceding the Civil

War. Prior to 1860 the South was rapidly outstripping New England and the Middle States in its total per capita wealth, production of agricultural products, railroad construction and manufacturing. After the Civil War, however, the South was in desperate financial and industrial straits until about 1880, when recovery began. Mr. Stone quoted numerous statistics from the "Blue Book of Southern Progress" to show developments in the Southern States since 1880, particularly in the growth of population, capital invested in manufactures, production of pig iron, bank deposits, and in the production of various non-metallic mineral products. For nearly all of these, the 1919 figure is double or more than double the corresponding figure for the entire United States in 1880 and in some instances is equal to the country's production in the census years of 1900 and 1910. These figures show clearly that the South has not been a laggard in the utilization of her natural resources. In concluding his address, Mr. Stone quoted several eminent chemical authorities to show that the South has great potentialities for the development of a chemical industry.

Manufacture of Phosphoric Acid in the Electric Furnace

The first paper at the afternoon session on Tuesday was delivered by Theodore Swann of Birmingham, who discussed the manufacture of phosphoric acid in the electric furnace. Mr. Swann, who is president of the Federal Phosphorus Co., described that company's operations at Anniston, Ala., where an electric furnace plant of eight furnaces with a total transformer capacity of 20,000 kw. is now in use. Electric power is supplied by the Alabama Power Co. from its hydroelectric plant on the Coosa River and is delivered to the furnaces at 44,000 volts.

The process consists in charging a mixture of phosphate rock, coke, sand and iron borings into an electric furnace and smelting to liberate the phosphorus. A ferrophosphorus, analyzing 24 to 25 per cent of phosphorus, is tapped off. Such phosphorus as is not absorbed by the iron is carried off in the furnace gases and oxidized by the air to P_2O_5. The furnace gases and phosphorus fume are then blown through a condensing apparatus and an electrical precipitator, where a strong phosphoric acid, containing as much as 90 per cent H_3PO_4, is collected. The iron in this product is said to be about 0.06 per cent and the As_2O_3 content 0.02 per cent.

A concentrated fertilizer using a high strength liquid phosphoric acid (62 per cent P_2O_5) to produce ammonium phosphate offers a promising possibility for this process. By adding potash to this compound a fertilizer containing three to five times as much plant food as the ordinary fertilizers is obtained. The development of such a product is of course dependent on its intelligent use by the farmer.

Petroleum Research

"There is urgent need of a promoting and co-ordinating agency to foster general petroleum research of a fundamental character, the results of which can be used by all those engaged in the development of the industry." So declared Dr. Van H. Manning, director of research of the American Petroleum Institute, in his address on "The Pioneer's Field in Petroleum Research." Although investigations and research of the highest order are being conducted in governmental, educational and industrial laboratories, this has been largely at the expense of unnecessary duplication of effort and of financial loss. The increasing necessity for greater efficiency and economy in the production and utilization of petroleum is a responsibility resting heavily upon the shoulders of American chemists.

Dr. Manning described his present paper as the first gun in a campaign to bring the problems of the chemist and of the industry to the attention of the corporations and others who are in a position to endow the undertaking of such a comprehensive research program. As indicative of the character and scope of the work which should be undertaken, a list of approximately seventy problems of the petroleum industry has been compiled by Dr. Manning and mimeographed copies were distributed to all who were interested in petroleum research. Many of the problems presented are too large for any single individual or institution to cope with unaided; others are so great as to require the collective resources of the nation's educational, governmental and industrial research departments; still others may require the establishment of entirely new research facilities.

This research program, which later was indorsed by the Section of Petroleum Chemistry, may be said to represent a broad picture of the future work which must be done in the production, transportation, refining, marketing and utilization of petroleum and its products.

Recent Developments in Chemistry of Rubber

A very clear résumé of recent work in rubber chemistry was given by Dr. W. C. Geer.

Crude rubber is apparently formed in certain glands of the rubber tree and put into the latex in the form of solid particles about 0.0005 mm. in diameter, so that 1 c.c. would contain about 50,000,000. The latex averages about 28 per cent rubber hydrocarbon, 60 per cent water, the remainder being resins, proteins and mineral matter. The proteins exert a protective action on the colloidal particles which varies among different species. Bacterial action upon the proteins starts immediately in the fresh latex, so that the coagulation must be carried out without delay.

Coagulation may be effected in various ways, but there is a decided need for a thorough chemical study of the whole subject. After washing, the soft dough or coagulum produced by the action of acetic acid on latex contains about 92 to 94 per cent of rubber hydrocarbon.

Dr. Geer emphasized the declining importance of wild rubber and predicted that it would soon practically disappear. He said that London was the financial center, Singapore the shipping center and Akron the manufacturing center of the industry.

One reasonably reliable means of determining the botanical origin of rubber is the acetone soluble, as determined by analysis. It is not, however, a guide to the quality of vulcanized rubber.

Brief reference was made to the importance of studies on the diffusion of gases through crude and vulcanized rubber. A rubber mixture in which poison gases are insoluble would be very desirable.

Much work has been done in recent years on the chemistry of vulcanization. It used to be thought that sulphur vulcanization did not take place until the melting point of sulphur had been reached, but it is now recognized that vulcanization is a function of time as

well as temperature, so that the amount of sulphur combined is proportional to the time at constant temperature. With 3 per cent of sulphur, a soft rubber is obtained, no compound between rubber and sulphur being formed. With excess sulphur, combination takes place up to 32 per cent, but the only compound formed is the monosulphide. As yet the mechanism of vulcanization is not well understood and it is not possible to remove the sulphur and get the rubber back.

Organic accelerators increase the turnover and have beneficial effect upon many of the properties. In this connection credit should be given to the Diamond Rubber Co. for pioneer work. In 1906, George Oenslager experimented with aniline as accelerator and in June, 1907, A. H. Marks used thiocarbanilide. Some modern accelerators are so powerful that the mixture will vulcanize over night at room temperatures.

In the case of fillers, particles of large size are not as strength-giving as smaller ones. The use of carbon black and zinc oxide is based not only upon fineness but also upon some other factor, probably interfacial tension or specific adhesion to rubber. Contrary to a common impression, fillers have a definite use and some of them cost more than the crude rubber, so that they are certainly not added to cheapen the mixture. The service test is the final judge of any mixture and the phenomenon of aging is receiving careful attention.

packing of food under actual factory conditions, the effect of various factors has been determined, among them preheating before sealing, exhaustion of air from the cans, life of typical spoilage bacteria, etc. Hydrogen sulphide, residual free oxygen in the pack, excessive treatment of hominy with lye and other causes of food discoloration are also important problems as yet unsolved.

No accurate basis for evaluating tin plate for can-making is known. The steel base, according to some authorities, should have carbon, silicon and sulphur respectively less than 0.2, 0.025 and 0.1 per cent and phosphorus between 0.05 and 0.1 per cent. But little is known as to the effect of extending the rolling time, annealing, methods of rolling, effectiveness of pickling or method of tinning. Usual practice demands open-hearth base for can ends, but bessemer steel is used for the bodies of the cans. The perforation of cans by fruit acids still remains a big problem and one not likely to be settled until more sound metallurgical research has been completed on these questions.

Informational Needs in Science and Technology

The circumstances leading to the organization of the Research Information Service of the National Research Council and the ambitious plans of that division for the cataloging and dissemination of scientific information

Carlile P. Winslow, Edgar F. Smith, Ellwood Hendrick, H. C. Parmelee, R. B. Moore, W. D. Collins, Rev. Father Coyle, W. H. Stone

In conclusion, Dr. Geer indicated the future of the industry and stated that the developments in the chemistry of rubber have resulted in improvements in the industry.

Research for the Canners

Problems of the canning industry which require research begin with the planting of suitable seeds and extend to the shipping, storage and spoilage of canned goods on the shelf of the merchant. Dr. W. D. Bigelow, director of the Research Laboratory of the National Canners' Association, discussed these problems broadly, with special emphasis on the importance and scope of those still awaiting solution. Food poisons and food values, including vitamines, both need attention, but the urgent industrial questions relate to processing of the canned goods to prevent spoilage. The three major and interrelated studies of Dr. Bigelow's laboratory are: (*a*) Determination of thermal death point of spoilage bacteria; (*b*) rates of heat penetration into foods during cooking or sterilization; and (*c*) effect of acidity (p_H number) on bacterial life.

The major troubles of the food canner are involved in spoilage or deterioration. By studies of experimental

was the basis of the address "Informational Needs in Science and Technology" by Charles L. Reese, chemical director of E. I. du Pont de Nemours & Co. Much time is lost and work is duplicated because of the fact that the tremendous fund of man's previous experience and knowledge is not conveniently available. The war emphasized the need for some central clearing house for scientific information and many individual attempts were made to organize such bureaus. Most of these have been abandoned because of economic pressure, although some are struggling to achieve self-support and profit. Dr. Reese expressed the belief that a general informational clearing house should be an endowed public service organization independent of the need of self-support or of gain.

As an example of the importance of classified information in connection with research, the speaker cited the information bureau of "das Königlische Materialprüfungsamt," which claims to be able to answer 80 per cent of the problems put up to it supposedly demanding experimental research.

The Research Information Service of the Research Council has been available for 3 years. Foremost

among the principles of policy are the desirability of developing a general clearing house for scientific information rather than a depository of knowledge, the conduct of free informational service for the promotion of research and the development of complete co-ordinated machinery for gathering, classifying and disseminating information.

It is proposed to extend this service eventually to an international scope, embracing the entirety of human knowledge.

Chemistry in the Old South and the New

Dr. F. P. Venable, past president of the Society, spoke on "Chemistry in the Old South and the New." He pointed out Charleston, S. C., as vying with Philadelphia in scientific inquiry during Colonial days, and he gave a short sketch of Prof. Emmet of the University of Virginia and of his distinguished pupil J. Lawrence Smith, who was later U. S. Commissioner to Turkey to aid that government in the development of Turkish mineral resources and in the growing of cotton. He also told of the work of Prof. Mallet, his own guide and mentor, of his atomic weight determinations, his production of ordnance for the Confederacy during the Civil War, his work on zirconium in which he proved Berzelius to be in error in his conclusions; his long professorship of industrial chemistry at the University of Virginia, and his many contributions to science.

The Civil War was followed by 10 years of so-called reconstruction which was worse than the war, and everything was wiped out. Work had to be done under the stress of extreme poverty. When the speaker was 23 years of age, completing his education in Germany, he received the call to take charge of the department of chemistry at the University of North Carolina. He had indeed full charge of it, inasmuch as his only assistant was a negro preacher. The laboratory was a cellar, now used for coal storage. The water supply came from a hogshead and their force pump was operated by this same darkey preacher-motor-power; and it was irregular. Iron sulphide was made at a blacksmith's forge and the work had the unexpected effect of instigating a revival in the church of his assistant, who had smelled the fumes of fire and brimstone, and with this experience he was inspired to lead sinners to the anxious seat and to rescue them as brands from the burning.

The university was closed during reconstruction days, and when it opened its income from all sources was $10,000 a year. Half of its alumni had been lost in the war. Today it has 2,000 students, an annual income of $750,000, and last year the Legislature appropriated $2,000,000 for new buildings and equipments.

He related many experiences and concluded with the statement that generally speaking in institutions of learning of the South, both state and private, the sciences are receiving important consideration. On the other hand, there is much need for more research. Many of those in control of these institutions oppose research as not within their scope, and this is an error which should be corrected. He said also that those in charge of Southern industries must awaken to the fact that this is a new world, and that they must be guided by science if they would prosper.

The Public Meeting

At the public meeting held in the auditorium of Hotel Tutwiler on Wednesday evening, Prof. Marston T. Bogert of Columbia University, past president of the Society, delivered an address on "The Flower Fields and the Organic Chemist. Perfumes, Natural and Synthetic." He outlined the very slight knowledge that we possess of this Cinderella of the senses, and indicated the belief that olfactory phenomena are of a chemical nature. He gave Boni's scale of three groups of odors, Zwaardemker's nine primary odors, and Henning's "smell prism" of six. He brought out the theory of correspondence between various odors and notes on the muscial scale, and he recalled Henning's dictum that we recoil from certain odors through the association of fear rather than from unpleasant sensations produced in the nose. He recalled the tradition that "over-indulgence in smell among a people is said to characterize a period of moral decadence." We are disposed to doubt this, however, and to attribute the dictum to the early Christian fathers, who were instigated by the anchorites to the belief that the world was straightway coming to an end, and that smelling was sinful because of its sex associations.

His talk was replete with miscellaneous information. For instance he said that 1 part in 8,000,000 of musk may be easily detected, but that so may 1 part in 10,000,000 of vanilla. Butyl mercaptan is noticeable in dilutions of 1 part in 460,000,000, and he said there are soil odors recognizable in even greater dilutions.

The Ainus of North Japan track their enemies by scent, just as a dog tracks game. The sense is more generally developed in men than in women. And since our senses are magnified as they are made to do the work of others that have been lost, he said Paris perfumers are training men blinded in battle to become perfumery experts.

Sharks have an olfactory organ 12 ft. square. Bears hate the smell of musk, but are especially fond of the odor of asafœtida. Bedbugs follow up the scent of their victims in seeking prey. Ants have a curiously combined tactile and olfactory organ which enables them to sense shape and odor at once. They know the age of one another by this means.

In Athens a popular place of meeting was at the perfumers' shops. Solon prepared a law that only men should be permitted to buy or use perfumery—and we should like to read the discussion that followed. The Arabs were formerly the great perfumers of the world, and they supplied Greece and Rome in the days of their respective greatness.

The lecture was followed by lantern slides showing the perfumery industry of France.

Division of Industrial and Engineering Chemistry

A short business meeting preceded the reading of papers before the Division of Industrial and Engineering Chemistry. A letter from Prof. J. R. Withrow recommended that no concerted action be taken by the American Chemical Society on the A.S.T.M. specifications for lime. P. H. Walker presented a report from the committee on methods of analysis and specifications for soap and soap powder, A. H. Campbell, chairman, representing the results of 4 or 5 years' work. It was adopted. H. E. Howe said that the committee on oils and fats, W. D. Richardson, chairman, was active and that a progress report would undoubtedly be ready for the Pittsburgh meeting. W. D. Collins reported progress for the committee on standardization. The gas chemists expressed a desire to hold a section meeting at Pittsburgh.

The feature of the technical program was a sympo-

sium on distillation, the fourth of a series of symposia. Plans for the program were upset in several cases, however, by the refusal of employers to permit the presentation of purely fundamental data. Automatic heat control was suggested as the topic for a symposium at Pittsburgh. Prof. R. E. Wilson felt that it should be extended to include all methods for process control.

Symposium on Distillation

Efficiency and Capacity of Fractionating Columns

Two viewpoints were taken in considering the efficiency and capacity of fractionating columns—the theoretical and the practical.

Prof. W. K. Lewis took up the theoretical phase and showed how it was possible to modify Sorel's mathematical treatment so that computation is simplified and graphical presentation of results is possible. As in Sorel's method, the enrichment from plate to plate was determined by equating the energy and material input and output, assuming that equilibrium was reached between the vapors and the liquid through which they bubbled.

Although the equations are applicable generally, they were developed for specific mixture, alcohol-water, in order to facilitate presentation. Considering a column in continuous operation with the feed entering at the middle of the column, the following equation was derived for the rate of enrichment or the rectification between any plate n above the feed and the next higher plate, $n + 1$:

$$\frac{dx}{dn} = k\left[(y_n - x_n) - \frac{V_c}{O_{n+1}}(y_c - y_n)\right]$$

where:

$\frac{dx}{dn}$ = rate of increase in concentration of liquid per plate.

k = fractionation efficiency of tower and plates; ratio of plates theoretically required to actual requirement.

y_n = mol fraction of more volatile component in vapor.

x_n = mol fraction of more volatile component in liquid.

V_c = mols of distillate produced per unit time.

O_{n+1} = mols of overflow from plate $n + 1$ to n.

y_c = mol fraction of more volatile component in the distillate produced.

Assuming perfect rectification, the equations developed were used to calculate the theoretical minimum number of plates required for a given rectification, by combining them with experimentally determined relation between x and y for mixtures under consideration. The result is an integral which may be evaluated graphically.

These equations were checked against experimental data on alcohol-water and hydrocarbon mixtures and found to agree satisfactorily.

As a further demonstration of the applicability of these equations, a practical problem was worked out—that of continuously rectifying a 10 per cent alcohol solution to produce a 94.5 per cent product and leave only 0.1 per cent in the waste. Factors to be determined were overflow or heat consumption, height of column or number of plates, point at which feed should be introduced. Plotting the results of the calculations indicated the following solutions to the problems:

The minimum overflow for rectification was found to be 3 mol per mol of product. When the influence of the amount of overflow per unit of distillate upon the number of plates required was considered, it was again apparent that an overflow of at least 3:1 was necessary. At this ratio an indefinite number of plates would be required as the curve became almost parallel to the axis. At an overflow of 4:1, 67 plates would be necesary; at 6:1, 36 plates, while at 20:1, 25 plates would suffice. Beyond this point there was no further appreciable drop, as the curve became parallel to the other axis. An economic balance between the cost of a column and the cost of heat to operate it can be struck from such a curve.

The feed should enter the column on that plate at which the enrichment curves for the bottom and the top of the column intersect. The author stated that so far as he knew this was the first method for determining the point at which the feed should enter. It would seem that in commercial practice the feed is often introduced too high up in the column.

H. E. Howe, W. Lee Lewis, Charles L. Reese, Van H. Manning, J. E. Teeple, William McPherson, Francis P. Venable, M. H. Ittner, B. R. Tunison

W. A. Peters, Jr., chairman of the symposium, explained how Prof. Lewis' method had been applied to plate columns of both sieve and bubbler cap type and to packed columns. It was found more convenient to use an arithmetical equation based upon Prof. Lewis' differential equation and also to use latent heat fractions instead of mol fractions. The relation existing between the compositions of the vapor rising from one plate, the liquid refluxing from the plate above and the heat balance in the theoretical column is given by the equation

$$X_{n+1} = \frac{y_n - y_c(1-\rho)}{\rho}$$

X_{n+1} being the equivalent latent heat fraction of the light boiling material in the liquid on the $n + 1$ plate; y_n the equivalent latent heat fraction of the light boiling material in the vapor rising from the nth plate; y_c the equivalent latent heat fraction of the light boiling material in the distillate; ρ the ratio of the heat required to volatilize the liquid run back divided by the total latent heat in the vapor passing up through any horizontal cross-section of the column. Equivalent latent

heat fraction is a term used to designate the heat required to volatilize the amount of light boiling material in 1 lb. of the mixture on or above the given plate divided by the latent heat required to volatilize 1 lb. of this mixture.

From this it is apparent that when ρ, y_c and y_n are known, X_{n+1} can be determined, which fixes the value of y_{n+1}, so that liquid and vapor composition at any point in the theoretical column may be determined.

Comparison between actual and theoretical columns may be made by determining ρ, y_n and y_c from a run on a given mixture and calculating the theoretical column which will give the same values for y_n and y_c with the same value for ρ. The number of plates calculated divided by the number actually required gives the efficiency factor, k, of the actual column. For filled columns divide by the height of the filled column. It was found more convenient to use the reciprocal of this efficiency, called the height of equivalent theoretical plate, *H.E.T.P.*

This method was first applied to a 28-in. sieve plate column with twenty-eight plates separating acetic acid and water, the distillate containing 98.52 per cent water and the liquid on the top plate 98.14 per cent water.

LOCAL COMMITTEE

Left to Right—A. G. Overton, J. T. MacKenzie, J. P. Montgomery, F. W. McMeans, J. R. Harris, R. W. Allen, J. F. Carle, M. Kuniansky, A. K. Boor and T. Swann.

Calculating one theoretical plate at a time, the fifteenth plate was found to give a liquid containing 98.1 per cent water and a vapor with 98.6 per cent. Thus fifteen theoretical plates will do the work of twenty-eight in the sieve plate column, so that the average efficiency k is $15 \div 28 = 0.536$.

Tests with alcohol-water mixtures in a standard 36-in. Badger bubbler cap plate column gave a value of 0.70 for k when less than 90 per cent alcohol by weight was contained in the mixture.

In order to account for the increased efficiency, two tests were made in the same bubbler cap plate column. k was found to be 0.45 for acetic acid-water and 0.694 for the alcohol-water, showing that there is a marked difference in the efficiency of the same column for different mixtures, although there is no difference between plate columns of either type under comparable conditions of immersion and size of perforations.

In the case of packed columns the efficiency was found to vary inversely as the diameter of the packing, while even greater divergence was noted between the efficiency for different mixtures than in the case of the plate columns.

The increased efficiency of packed columns when small packing is used is offset somewhat by the cost of the smaller fillings. In determining the cost it is necessary to consider the capacity factor, which for practical design purposes may be measured by the maximum vapor velocity which a given column will stand without priming. Small hollow cylinders make an ideal filling material and the author announced that his company had patented a method for making ¼- to ⅜-in. hollow cylinders at an estimated cost of about $30 per cu.ft., which is in sharp contrast to the figure of $250 per cu.ft. quoted by a London firm for ¼-in. rings patented by Dr. R. Lessing and described in *J. Soc. Chem. Ind.*, 1921, vol 40, pp. 115-119.

Assuming the lower figure for the small rings, a comparison was made between the cost of a cast-iron bubbler cap plate column and a column packed with ¼-in. cylinders, each to be equivalent to fourteen theoretical plates and to deliver 41 gal. of 92.5 per cent alcohol per hour with an average value of 0.8 for ρ. From the data for maximum vapor velocity, the diameter of the plate column must be 24 in. and of the packed column 18 in. The height will be twenty plates and 4.7 ft., respectively. A cast-iron column of this size actually cost $1,300 in 1919, but could probably be made now for $1,000. The cost for the packed column was estimated as $365. In the case of acetic acid-water separations the cost of the packed column was not found to be much lower ($1,200, against $1,350), but the life should be much longer.

A valuable feature of this method is that it makes possible direct comparisons between laboratory and plant fractionating columns, so that a large column can be designed to make any desired separation which has been made in a laboratory column.

Plate Efficiency of a Continuous Alcohol Still

A paper by Clark S. Robinson on the plate efficiency of a continuous alcohol still was summarized by Prof. W. K. Lewis. Three tests on an alcohol column gave widely varying plate efficiencies, ranging from 24 to 56 per cent. In discussion it was pointed out that in most of the earlier data on this subject either the heat consumption or the concentrations on the plates was omitted.

Simple Distillation of Hydrocarbon Mixtures

Prof. W. K. Lewis presented the results of work done with C. S. Robinson on the simple distillation of hydrocarbon mixtures. Gasoline is a mixture of hydrocarbons whose boiling points range from 50 to 200 deg. C. The usual test is an Engler distillation. The refiner would like to know what his plant results are going to be from such a laboratory distillation. Prof. Lewis found that with a mixture of 65 per cent benzene and 35 per cent toluene the curve for simple distillation calculated from Raoult's law checked the Engler curve within 1 deg. except near the end of the curve. This deviation was found to be due to rectification which could be eliminated by slightly superheating the still head. This method may be applied to gasoline.

Benzene Purification

A very thorough discussion of the steps involved in the purification of benzene from absorption in straw oil was given by S. S. Heide. The crude is first fractionated to give 70 per cent of 90 per cent crude benzene, 13.5 per cent of 90 per cent crude toluene, 4.5

per cent each of crude light solvent and crude heavy solvent and a residue containing 5 per cent wash oil and 2.5 per cent naphthalene. The working up of each fraction was then considered in detail.

Wood Turpentine

C. A. Lambert described the production of wood turpentine from stumps, downwood or slabs by steam distillation. A charge of 14 tons gives 112 gal. of crude wood turpentine, which upon refining gives 60 per cent pure wood turpentine and 40 per cent pine oil. The physical properties of each 5 per cent fraction were presented in tabular form.

Calculation of Heats of Vaporization

There being no adequate data on heat of vaporization of liquids, Prof. W. K. Lewis and Harold C. Weber pointed out the possibility of calculating these from Hildebrandt's modification of Trouton's rule and from vapor pressure curves.

Glycerine Distillation

Recent developments in distillation systems for the production of dynamite and chemically pure glycerine were outlined by J. W. Bodman. Steam for the spray in the still is supplied by the sweet-water evaporator which is made a part of the unit under vacuum. By means of suitable heat exchangers over 90 per cent is recovered directly as dynamite glycerine as compared with 75 per cent under the older systems. In addition to this and the reduced steam consumption, floor space is economized.

General Papers

Whitewashes and Alkaline Paints

Investigations carried out in the research laboratory of the National Lime Association on whitewashes and aqueous lime paints were summarized by Dr. G. J. Fink.

Of the siccatives used, those such as casein, which with lime form insoluble films, proved to be the best, while those which are water-soluble, such as glues, are not so satisfactory for exteriors. Several alkaline salts were used for accelerating the solution of casein, trisodium phosphate proving to be the most satisfactory. Among the addition agents used with lime in mixtures containing no definite siccative alum and table salt were effective in improving the workability and permanence of the whitewashes. Several formulas developed and tested were shown to be superior to most of those in common use.

Discontinuous Extraction Processes

L. F. Hawley made a study of Turrentine's kelp char extraction process (*J. Ind. Eng. Chem.*, 1921, vol. 13, p. 605), according to the theory of discontinuous extraction formerly developed (*J. Ind. Eng. Chem.*, 1917, vol. 9, p. 866). By using Turrentine's data in the mathematical theory of the process it is shown that the incomplete extraction is due to the fact that complete solution of the potassium chloride was not obtained in the first treatment of the raw material. The other conditions of extraction were so efficient that the final recovery was only slightly less than the theoretically perfect recovery with the solvent ratio and number of treatments employed in the process.

In answering the question, "Can We Afford to Make Potash in America?" R. Norris Shreve reviewed conditions in the domestic industry and drew up a balance sheet of debits and credits to show the necessity for tariff protection.

Fuels, Engineering and Chemistry

Eight of the papers of this Division dealt with problems of fuels chemistry or fuels engineering and formed virtually a second symposium. A. C. Fieldner and G. W. Jones, of the Bureau of Mines, presented further results on their studies of internal combustion engines, discussing particularly "carburetor adjustment by gas analysis." The relation of the pounds of air per pound of gasoline varies widely with commercial service station adjustments. The results of road trials on various cars shows that about 13.5 lb. of air per pound of gasoline burned is the average ratio for maximum power; 15 lb. for theoretical complete combustion; and about 17 lb. for maximum efficiency (miles per gallon). The carbon dioxide percentage in the exhaust which corresponds to these several air-gas ratios is definite. For example, 12 per cent CO_2 in the exhaust is equivalent to a carburetor adjustment for maximum power. An ordinary adjustment corresponds to about 70 per cent completion of combustion on the average, whereas a good carburetor adjustment easily reaches 85 per cent combustion.

With some carburetors, adjustment by methods of analysis at one rate of operation permits good operation at other rates. Such carburetors are regarded as properly designed. Other carburetors have the reverse direction of trend in curve with change in rate of operation and consequently cannot be accurately adjusted for all rates of use. Using the method of gas analysis on the exhaust as the basis of adjustment, these investigators have found generally that 20 to 60 per cent increase in mileage per gallon is easily attained. Methods for sampling of exhaust gases and for adjustment of carburetors on the road are described fully.

Classification and Analysis of Coal

S. W. Parr, of the University of Illinois, proposed in his first paper a new classification of coal based upon its heating value per unit of coal substance and the per cent of volatile matter contained. Former methods of classification were based largely upon the ratio of the volatile matter to the fixed carbon of the coal. Parr proposes to determine the unit heat value of coal substance by subtracting from the total B.t.u. 5,000 times the percentage of sulphur and dividing the remainder by 1 minus the sum of 1.08 times the ash plus 0.55 times the sulplur. This gives a true heat value for the coal substance itself without regard to the percentage of the ash or sulphur contained.

A large number of data were presented to show that wide variation in the heat value of coal substance would be found on identical coal by the ordinary method of calculation. The variation with different ash or sulphur content on coal from the same seam or mine is usually 125 to 250 B.t.u. and sometimes reaches 1,100 B.t.u. But the Parr formula calculated on different samples from the same seam or mine invariably gives agreement within the limits of experimental error for the heat value determination. The discrepancy between clean and dirty fractions from coal washing were usually less than 50 B.t.u., in only one or two cases reaching 80 B.t.u. The results are so accurate that it is possible to detect by this means the county within the State of Illinois from which coal comes or to identify the seam from which it comes. In other words, this method gives a significant characteristic of any particular type of coal independent of the variation of ash or sulphur in

the particular sample examined. This is true not only for mid-continent coals but also for samples from South Africa, Brazil, West Virginia and other bituminous coal territory and also for cannel coals, sub-bituminous and anthracite.

Parr proposes a chart using the heating value per unit of coal substance as one co-ordinate and the volatile percentage as the other. This classification groups the coals as follows:

	Heating Value Per Lb. of Coal Substance
1. Brown lignite	11,500-12,500
2. Black lignite	12,500-13,500
3. Sub-bituminous	13,500-14,000
4. Western bituminous	14,000-15,000
5. Eastern bituminous	15,000-16,000
6. Anthracite	15,500-16,000

Thus it is noticeable that on the basis of heat value alone the lignites and younger bituminous coals are differentiated sharply, but the actual percentage of volatile enters to distinguish between coals of similar heat value but of different percentage of volatile ranging in the order anthracite, semi-anthracite, low volatile bituminous (Pocohontas type), Eastern bituminous and cannel coal, all of which have about the same heat value per unit of pure coal.

Parr also reported on a method for the ultimate analysis of coal by use of sodium peroxide fusions. He considers this method quite good enough for engineering work and particularly important where calculation of stock losses is desired. The calculation determines the hydrogen content of the coal by subtracting from the total heat the heat from the carbon (8,080 calories per gram), and that from the sulphur (2,777 calories per gram), and dividing the remainder by 24,450 (the heat value of hydrogen in calories per gram). Calculation is also made on the assumption that the nitrogen in the coal is 1.25 per cent (a figure quite generally applicable), and thus a determination of oxygen in the coal is possible by subtracting from 100 the sum of the percentages of carbon, sulphur, hydrogen and nitrogen. In discussing this paper by Parr, W. K. Lewis and A. C. Fieldner outlined briefly other crude engineering methods for similar calculation of ultimate analysis.

Heat Value Of Wood

A third report by Parr gave data on the heating value of wood as follows: Oak, 8,550 B.t.u. per pound; pine, 8,836; birch, 8,458. These three woods when thoroughly air-dried contain moisture removable at 105 deg. C., as follows: Oak, 8.35 per cent; pine, 8.88 per cent; and birch, 10.18 per cent.

Melting Point Of Coal Ash

A. C. Fieldner, W. L. Selvig and W. L. Parker, of the Bureau of Mines, Pittsburgh laboratories, reported on comparisons of the standard gas furnace and micropyrometer methods for determining the fusibility of coal ash. In the air the micropyrometer method does not agree at all well with the gas furnace method, but when used with a reducing atmosphere about the sample the agreement is good for ash samples melting not higher than 2,600 deg. F. With samples melting above this point the micropyrometer method gives distinctly different results than the furnace method. In the case of the micro method, the vitrification or fusing of fine edges of the ash particles is observed. In the case of the furnace method using cones, it is the slagging of the mass as a whole which is observed. On chain grates coals which slag are objectionable. With underfed stokers only vitrification of ash substance is sufficient to give trouble. Therefore for the two types of furnace use the two methods of laboratory determination may be correspondingly significant. However, as yet this practical feature of the work has not been settled. In the investigation the Bureau of Mines has had the cooperation of the Bureau of Standards, the New York Consolidated Gas Co., the United Gas Improvement Co., and others. In these co-operative tests it has been found that the micro methods check to about the same extent in most cases as do the furnace methods—that is, ranging over about 100 deg. F. between different laboratories. The same man working with one apparatus usually finds variation of not over 40 deg. F. between tests on the same sample.

Coke Properties And Use

H. J. Rose, of the Koppers Co. laboratory, Pittsburgh, presented a paper on the determination of specific gravity of coke. He points out that the fineness of grinding is important. He recommends water as the wetting medium with 200-mesh coal boiled for 30 minutes. His results are not yet definite as to whether or not a vacuum must be used to get complete wetting in the pores.

S. P. Kinney and G. St. J. Perrott, of the Bureau of Mines, Tuscaloosa Station, reported preliminarily on "The Shatter and Friability Tests for Metallurgical Coke." The general conclusion which these investigators have reached is that friability-test results are of no meaning whatsoever. Results of the shatter test are of little greater significance. The average deviation of tests on the same coke, even though made as carefully as possible, will be several per cent. Hence it is altogether impractical to use this test as a guide for oven operation. Results were presented on work done by all of the customary methods, including the drop test, the bag test, the revolving drum method, etc.

G. St. J. Perrott and H. W. Clark reported very fully on the results of their investigation in Salt Lake City, where they participated in the Bureau of Mines' study of the smoke problem of that community. Their results on coking of Utah coals have already been published in Chem. & Met. In this report they developed somewhat further the estimate of cost of coke and of the market for byproducts in that territory. Their figures indicate that it will be impractical for a coke plant to be established in Salt Lake City of sufficient size to meet the need for smokeless fuel if coke is to be substituted for bituminous coal generally. The market for byproducts in that territory is wholly inadequate to absorb at a favorable figure the output of a plant of that size.

Section of History of Chemistry

The Section of History of Chemistry has a good start, and so long as Drs. Edgar F. Smith and C. A. Browne are in the saddle, the Section is sure to thrive. Dr. Smith presented a sketch of Dr. Thomas Cooper, an Englishman by birth, a brilliant student at Oxford, but so radical in his views and so outspoken and insistent in his opinions that waves of trouble were always rolling about him. He was a jurist and served as Circuit Judge in Pennsylvania, he practiced medicine successfully, and was finally appointed to the chair of chemistry at South Carolina State College at Columbia. Dr. Browne harked back to early references to chemical warfare, while Father Coyle of Holy Cross College, Worcester, Mass., told a thrilling list of the achievements of a Jesuit priest

named Anastasius Kirchen who lived 1602-1680, invented the magic lantern as an incident, but who was in effect one of the fathers of modern chemistry. A number of other interesting papers were presented.

Section of Chemical Education

The Symposium on Chemical Education was carried on under the chairmanship of President Smith, and it proceeded without a dull minute. The papers had to do with high school and first year college chemistry and the training of chemical engineers. In teaching high school chemistry, for instance, the question was raised whether it was not better to begin with metals and more tangible things than with gases and the difficulties of the gas laws to young minds. It seemed to resolve itself into the conclusion that the first thing to accomplish is to arouse the interest and curiosity of the pupils—and when this is accomplished the rest is easy.

What to do with high school chemistry in college was a harder question. In some colleges preliminary teaching of the subject is not recognized, and in others freshmen are divided into those who have had chemistry and those who have not, but this does not always work out well. Many who have "had chemistry" and even passed their examinations don't know anything after all, while others are well prepared. It was a hard nut to crack. At one university they have two classes scheduled for the same hour, and at the end of the first month many who have entered the more advanced class drop back into that which is elementary. But even that is not satisfactory, and the problem seems not yet solved.

There was considerable discussion on what the function of the first year's course in chemistry is, whether formative or informative. Father Coyle of Holy Cross College, Worcester, Mass., believed that the study of chemistry develops character. But the question would not down as to whether the first year of chemistry belongs properly in the secondary school or in college.

The "Project Method" of Teaching Chemistry

Prof. Gordon of the University of Maryland outlined a very interesting "project method" for teaching chemistry. This consists in re-writing the book, leaving out whatever may be easily discovered. It brings the classroom into complete co-ordination with the laboratory, for what is left out in the book and discussed in the classroom becomes the subject for study in the next laboratory period. The vacant spaces are filled in by the students, and the books are checked up before they are taken out of the laboratory. In the first half hour of the class following the laboratory period there is a quiz on what has been done, and a correction of all errors made, while the latter half of the hour outlines again work which is to be completed in the laboratory. It works well with about 400 students, on a basis of 2 hours lecture and quiz to 3 hours laboratory. It challenges the students to think, and they get credit for their thinking.

In the afternoon session the Massachusetts Institute of Technology plan was outlined, in which students spend a fifth year in industries, and there followed a general discussion, with papers interspersed, of chemical engineers.

Industrial Chemists Wanted

It seemed generally agreed that in 4 years' time it is impossible to train a good chemist and a good mechanical engineer at once. Either the chemistry or the mechanics must suffer. It was suggested that what is wanted is industrial chemists, and not mechanical engineers with a smattering of chemistry. In response to the question of what a chemical engineer should be, credentials offered by applications for positions were quoted, in which, in very defective English, the applicants had shown their studies of chemistry, physics and mathematics to be in the ratio of 12 to 1 to 1½. In other words, they had "boned up" on chemistry and did not know anything else. What to do with those roughnecks in professional life seemed another unsolved problem. Somebody proposed that applicants for positions be required to send moving pictures of themselves at table, and phonograph records of their colloquial discourse.

Teaching Methods in Vogue Elsewhere

Prof. Bogert of Columbia described methods in vogue at Columbia and Prof. Charles W. Evans circulated a series of charts which he had found very helpful in teaching organic chemistry. Lively discussion was elicited by Prof. H. A. Webb of Teachers' College, Columbia University, who presented a paper on "Standard Tests in Science, Especially Chemistry." These were drawn up on the basis of "mental tests." They show up the unpreparedness of students in an amazing manner, and enable the authorities to weed out much earlier in the process than otherwise those who cannot learn. By standardizing they make marking easy: the professor's secretary can do it by means of a key, whereas if tests are not standard there are scarcely two instructors who mark alike. Against the system is its somewhat mechanical nature of treating all students alike when they are individually different, and the fact that its whole merit is lost if advance copies of the questions get around. But a number of professors seemed to feel that a great advance had been made in the art of examining, and that these new standard examination papers should be warmly welcomed.

Prof. J. P. Montgomery of the University of Alabama told of his plans for chemistry courses, and Prof. Edward G. Mahin of Purdue presented a paper on "Science or Athletics?" It doesn't take much imagination to picture the plight of a professor of science who is trying to lead his students along into the paths of

wisdom, and to compare the piffling unimportance of his message with that of the cheer leader. It was a sad paper, that viewed the matter with alarm, but it found such favor among the auditors that the author was urged to have it published. Somebody suggested that it wasn't athletics that dragged students down as much as the quality of the young men themselves that could not reach up. But that was not a popular view.

The foregoing is a record of impressions rather than a detailed report of the meeting. Dr. Smith's frequent and illuminating comments and anecdotes made it really a memorable occasion; and if we had the space we would gladly tell more. If nothing definite was accomplished, it was, nevertheless, full of leads and in this respect it was said by a number of those present that, for their own purposes, it was the best meeting ever.

Section of Petroleum Chemistry

The Petroleum Section, first organized a year ago at the Rochester meeting, is one of the youngest sections to become a Division of the Society. This authorization, recently approved by the Council, is to take effect at the Pittsburgh meeting in September, 1922. The encouraging progress made as a section speaks well for the future success of the new Division of Petroleum Chemistry.

In the absence of Chairman T. G. Delbridge, Vice-Chairman D. K. French of Chicago presided at the two sessions on Wednesday, April 5, during which a number of interesting papers were read and several important items of business transacted. Some changes were proposed in the Section's constitution and bylaws, and after discussion by Dr. W. F. Faragher and the secretary, Dr. W. A. Gruse, the following resolution was adopted as a definition of the scope of the Petroleum Division: "The Division of Petroleum Chemistry shall devote its attention to the chemistry of petroleum and its products and not to the preparation of standard methods of tests and specifications; however, it shall at all times be the spirit of the Petroleum Division to co-operate if desired with other scientific societies and agencies interested in this field." In other words, a clear line of division is made between the Petroleum Division's activities and those of the A.S.T.M. committee D-2 and similar agencies interested in marketing and buyer-and-seller problems.

Physical Properties of Petroleum Oils

The first paper on the program was presented by A. P. Bjerregaard, chief chemist for the Empire Refineries, Inc., who discussed the effect of temperature changes on the volume of petroleum products, as well as the losses by evaporation and from entrapped air. His conclusions on these important questions and other useful data regarding the expansion of petroleum oils have been published in a pamphlet, which is being distributed from the company's offices at Tulsa, Okla.

An interesting discussion of viscosity measurements and the surface tension of petroleum oils followed the reading of papers by C. K. Francis and H. T. Bennett of Tulsa, of W. H. Herschel of the Bureau of Standards and W. A. Fulweiler and C. W. Jordan of the United Gas Improvement Co., of Philadelphia.

Blended Motor Fuels and Knocking

Thomas Midgley, Jr., of the General Motors Research Corporation, read a paper by T. A. Boyd and himself in which he discussed the detonation characteristics of aromatic and paraffine hydrocarbons such as met with in blended motor fuels. Knocking in internal combustion engines has been shown to be dependent on the chemical composition of the fuel and its pressure of detonation and not on pre-ignition, to which it is generally attributed. The compressions to which aromatic hydrocarbons can be subjected without detonation are very high as compared with the initial compressions that can be employed when paraffine hydrocarbons are used. But little has been known regarding the relation of the composition of blends to their detonation tendencies, one of the reasons being the lack of a suitable apparatus for conducting such tests. The laboratory of General Motors has, however, developed a special instrument consisting of a small auxiliary cylinder tapped into the cylinder head of a gas engine. The piston of this small cylinder is held firmly in place by a strong spring, but in such a way that its vibrations can be measured electrically. With the use of this instrument accurate measurements were made for a wide range of blended fuels and values were given for the limiting compression ratios at which the different blends will give combustion that is free from detonation.

Corrosion of Petroleum Refining Equipment

Ralph R. Matthews and Philip A. Crosby in two previous papers[1] had shown that in distilling mid-continent petroleum in a so-called pipe still, HCl was formed due to the hydrolysis of $MgCl_2$ in the brine associated with the crude oil. The authors used ammonia in their fractionating columns and succeeded in combating the corrosion at a comparatively small cost. This article, together with photographs of the corroded parts, will be published in an early issue of Chemical & Metallurgical Engineering.

Extraction of Gasoline From Natural Gas

F. M. Seibert, in a paper prepared by F. E. Hosmer and himself, reviewed the natural-gas gasoline industry from 1904, when two plants produced a total of 16,000 gal., to 1920, when 650 plants had an output of 483,000,000 gal. He then outlined one of the methods of gas extraction in which a great deal of progress is now being made. The author referred to the low-pressure evaporation method in which the crude product is utilized to furnish refrigeration for cooling the gas after being subjected to pressure.

After discussing briefly the use of solid absorbing materials such as activated charcoal and silica gel, attention was directed to the liquid absorbents of which either crude oil, mineral seal oil, naphtha or low-grade gasoline is used. In the crude oil process it was stated that the best results could be obtained by subjecting the gas to about 50 lb. pressure at ordinary temperatures and absorbing the gasoline at a saturation ratio up to 25 per cent.

Research Program Indorsed

The concluding feature of the Section's program was a conference on the promotion of research on petroleum. Naturally the research program outlined by Dr. Van H. Manning in his address before the general meeting of the Society formed the basis of this discussion. Willing co-operation was expressed by Dr. Bjerregaard and others. Finally by official action the Petroleum Section went on record as indorsing Dr. Manning's program and voted to appoint a committee, which should include

[1] Chem. & Met. Eng., vol. 22, No. 11, p. 491, and vol. 23, No. 23, p. 1128.

representatives of the Bureaus of Mines and Standards, and which should co-operate with Dr. Manning in promoting joint research on the chemistry and chemical technology of petroleum.

Division of Sugar Chemistry

The color of sugar and sugar products and use of various materials for decolorizing them were the subjects of discussion in one group of papers presented before this Division. There were also, of course, several important reports on analytical methods and apparatus for testing of sugar or its byproducts.

The color of the solution of a sugar is certainly not a good index of purity. This fact was well demonstrated by the data presented by F. W. Zerban, who discussed "The Color Range of Cane Sirups and Molasses." Data on about 1,000 samples were reported to show the relation between the color as tested on diluted specimens in the Hess-Ives instrument in comparison with the "purity." Only 56 per cent of the samples follow the rule of color relationship normally expected, according to Zerban's data. He presented a curve of the relation between these properties for products of Louisiana plants using the sulphitation process and developed a mathematical expression of the curve. However, this curve did not apply to Cuban molasses at all. It was shown also that where carbon had been used in connection with the processing the color was lighter than would normally correspond to the purity for similar materials not so treated. The importance of color rather than purity in fixing the commercial value of a sugar was made clear by a discussion of the results.

Decolorizing Principle of Bone Char

A preliminary report on "The Decolorizing Power of Bone Char," by P. M. Horton, was presented by C. E. Coates. Horton discussed the earlier work of Hall and of Patterson on the influence of nitrogen in bone black upon its decolorizing power. The earlier workers claim that the nitrogen-bearing bodies were the active element or at least contributed largely to the activity. Horton digested samples of the material on the water bath for 1 hour at 90 deg. C. with concentrated sulphuric acid, filtered, diluted, obtaining a gelatinous flocculent precipitate. Another sample was digested for several days with acid at room temperature and the precipitate similarly obtained. Both precipitates were dialyzed free from acid and tested for decolorizing value. It was found that when the acid was eliminated thus, the results reported by the earlier workers were not duplicated. It is therefore concluded that the activity of the char when affected by treatment is due to a change in the structure or surface of the carbon and not simply to the removal of the nitrogen-bearing material. The earlier workers probably mistook the decolorizing effect of the acid remaining in the nitrogenous material for a property of the material itself.

Bone Black vs. Activated Charcoal

C. E. Coates strongly advocated the manufacture of plantation standard granulated sugar either with or without activated char instead of shipping the plantation sugar to a refinery "owned by the trust." Emphasizing the importance of uniform size, color and purity of the finished granulated sugar for maintenance of regular trade, he insisted that small plants handling about 50 tons of sugar per day were reasonably efficient units for neighborhood operation. Even though probably not as efficient as big plants, they can be operated well enough to pay profits to plantation sugar mill owners, for the additional investment would be between $25,000 and $50,000, especially if no additional buildings were required. Any animal or vegetable chars, including bone black, require care for refinery use. Activated carbon can be used with much cheaper installation than is possible with bone black, but certain disadvantages are sometimes met, for chars are sold on a royalty basis, often with exaggerated claims as to their possibilities, and no standard procedure for use has been generally established. Difficulty in filtration of material decolorized by activated char is met if great care is not used; but with proper chemical research and development, Prof. Coates believes there is some net advantage for the activated char in comparison with bone black. He states the loss in reactivation is 1 to 2 per cent, but care and proper treatment is essential or the value after processing is seriously decreased. Reactivated char costs $15 per ton for recovery, in contrast from six to ten times this price for new material. It can be used thirty to fifty times before discarding and the total cost of the char should be about 2c. per 100 lb. of sugar refined. This is a trifle higher than bone black cost, but the investment is sufficiently less to offset the difference.

Color and ash absorption by bone black and by decolorizing carbons was discussed by W. B. Horne, who claimed that the carbons, though superior in color absorption, removed no ash. Tests of carbon fixed on a porous earthy base gave encouraging results for ash as well as for color removal. Dr. Horne assumes in his comparison that removal of 0.2 per cent of ash from the raw sugar by bone black gives a 1 per cent increase in sugar recovery; however, he does not reconcile this with the ratio of 2 to 1 commonly reported by refiners. His cost comparisons are all on the 5 to 1 assumption.

C. E. G. Porst, director of research of the Corn Products Refining Co., with M. Moskowitz, discussed plastometer tests on alkaline thin boiling cornstarches, giving a mathematical and experimental report of results. Alkali addition produces a firmer paste almost up to the neutral point, but further addition weakens the paste, though it makes it smoother, translucent and of better spreading power.

M. Louis Baissac of the Island of Mauritius informally discussed some of the conditions and problems of sugar production in the tropical islands of Australasia. Much plantation white sugar is made in that territory, but no decolorizing carbons are used there as yet. The luxuriant growth of vegetation in some of this country is well shown by the yield on certain special plots of cane where 15 to 17 tons of finished sugar per acre have been manufactured in certain seasons.

Division of Physical and Inorganic Chemistry

The growing interest in colloids was reflected in the fact that one-third of the papers of this Section were devoted to colloidal or closely related subjects. The start is being made to place the study of the physical properties of colloids on a quantitative basis. Important additions to colloidal science, followed shortly by industrial applications, are bound to result from this method of treatment.

Whenever a capillary tube method is used to measure the viscosity of a viscous liquid there is an error due to incomplete drainage which is larger the greater the

viscosity and the shorter the time of drainage. This error may be as great as 1.5 per cent. A table should be worked out for the corrections required for oils of different viscosity and for varying drainage periods, according to Bingham and Young of Lafayette College. The present unsatisfactory means for comparing the yield value and mobility of a paint with its so-called painting consistency was pointed out by Bingham and Bruce. A committee recently appointed to report on standard samples of paint had been able to make only rather rough estimates. By plotting the volume flow against shear the results lie on a straight line within the error of the stop watch used. This line when extrapolated to zero volume flow should give a value accurate to a very few per cent of the minimum yield value of any given plastic material. In the discussion it was brought out that starch pastes follow a slightly curved line and gelatine a straight line.

Crystalline Structure

Two papers were presented on the lattice structure of crystals. Dr. Sosman showed a model to help explain the idiosyncrasies of silicon dioxide in its various minerals, while Dr. Wherry is of the opinion that the electrons are held rather rigidly in the crystalline lattice and that frequently an electron is shared by more than two atoms. The conception of the "domain" of the atom was defined as the space reserved for each atom as bounded by planes which bisect the lines joining atomic centers. The fact was pointed out that very few of the atomic domains were in the simplest geometric forms but occurred usually in truncated modifications thereof.

Papers by Edward C. Franklin and by Cady and Elsey described some interesting reactions taking place in anhydrous ammonia and pointed out the similarity of nitrogen and oxygen compounds—e.g., nitric acid and its counterpart, ammono-nitric acid or hydrazoic acid.

Glue and Gelatine

Dr. R. H. Bogue of the Mellon Institute read an interesting paper on the connection between the hydrogen-ion concentration and the properties of emulsoid colloids. In the determination of the content of jelly a concentrated solution of magnesium sulphate is used to precipitate out the jelly which is least soluble at its isoelectric point. In studying the joining strength, so important for glues, the optimum acidity produced a change in the viscosity of a 1 per cent solution by only 7 centapoises from the least favorable concentration. The determination of viscosity with an ordinary pipette involves a change of about 10 centapoises for every second read on the stopwatch—far too crude a measure. At the isoelectric point the ions of electrolytes are most easily washed out. There are a very great number of plant operations where the concentration of the hydrogen ion should be known and controlled.

Ash-free gelatine was prepared by Sheppard and Sweet of the Eastman Research Laboratories by passing a 220-v. direct current through a 5 per cent gelatine near its isoelectric point. Then on precipitating with redistilled acetone but 0.01 per cent ash was left. The elasticity as shown by twisting various cylinders of different concentrations of gelatine did not have any special properties at the isoelectric point. The interfacial tension against toluene, on the other hand, was found, by the drop number method, to exhibit maxima at the isoelectric point for most concentrations and at a variety of temperatures. The addition of aluminum salts caused a shift of the maximum to the alkaline side. Inorganic gels are formed either by an interlacing of threads or by films surrounding the disperse medium, according to Dr. Harry B. Weiser of the Rice Institute. A study of the behavior of dibasic organic acids and ethereal salts on water surfaces was described by King and Wampler in light of recent work by Langmuir and Harkins. In general, the adsorption of the dibasic acid is less than that of monobasic acids, although the results among different acids are somewhat irregular. Prof. Jack P. Montgomery of the University of Alabama described the adsorption of alkali halides by barium sulphate as being almost in the order of molecular weights. Lithium chloride was scarcely adsorbed at a concentration up to a millimol in 50 c.c.

New Apparatus

An interesting thermoregulator has been developed by E. B. Starkey and Prof. Gordon, as shown in Fig. 1. The tarnishing of the surface of mercury where the make and break occurs is done away with. The capillary tube contains air, but the oxygen is eliminated with the first spark or two. Toluene is placed in the bulb and the amount can be regulated through the stopcock *S* when working at different temperatures.

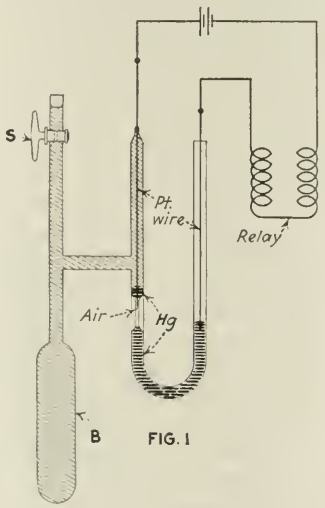

FIG. 1

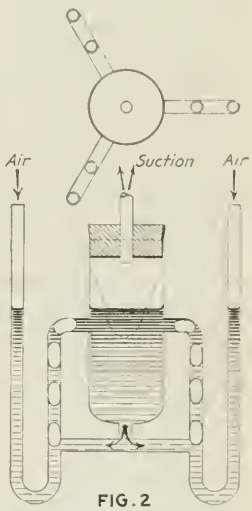

FIG. 2

FIGS. 1 AND 2—SKETCHES OF NEW APPARATUS
1—A thermoregulator with a clean mercury contact surface.
2—A simple cell for rapid electroanalysis.

A simple and easily constructed cell for rapid stirring of the electrolyte was described by Prof. Edgar of the University of Virginia. By applying water-pump suction to the top of cell, as shown in Fig. 2, air is drawn up through the three side arms so rapidly that a marked vortex is produced. This eliminates any tendency to entrain spray and permits very rapid analytical depositions.

Section of Cellulose Chemistry

The work of the Forest Products Laboratory stood out prominently in the meetings of the Cellulose Section, at which thirteen papers were presented and discussed. The report of the committee on the preparation of standard cellulose was accepted with certain modifications. In this connection W. O. Mitschlering, Atlas Powder Co., read a paper on the "Use of Standard Cellulose." The object of the investigations reported was to introduce a normal cellulose into experimental laboratories. It was found that when normal cellulose was used for nitrating purposes, the spent acid obtained was purer than that from the nitration of ordinary

plant cellulose, the product was more uniform and the loss of cellulose during nitration was lower. A revised method for testing the viscosity of cellulose solutions was devised by which the cellulose passes into solution immediately and is tested in a neat falling sphere viscosimeter designed by the author.

Harold Hibbert presented a résumé of work done by himself and co-workers on the synthesis of various cyclical acetal derivatives. The value of the work as stated by Dr. Hibbert lies in the fact that such derivatives are very closely related structurally to the pentosanes, hexasanes, starch and cellulose. It is hoped that from a knowledge of the behavior of these synthetic products toward acids, alkalis, bisulphites, etc., valuable information will be obtained relative to the action of sulphites, for instance, on related derivatives present in wood. Knowing the limits within which the stability of such materials lie may result in information which will make possible increased yield of paper pulp by the bisulphite process.

Work of Forest Products Laboratory on Hydrolysis and Fermentation

Five of the papers from the Forest Products Laboratory were read by E. C. Sherrard. One of the most interesting discussed the manufacture of "Ethyl Alcohol From Western Larch." The idea prompting the investigation was that since the butt logs contain 10 to 25 per cent galactan they constitute the best source of this material and that if a similar quantity of sugar is obtainable from larch cellulose in addition to that in the galactan, this would be an excellent source of alcohol. Galactan was extracted with hot water, hydrolized and fermented. The residue from the water extraction was hydrolized (15 minutes at 115 lb. steam) with sulphuric acid, and the resulting sugars extracted. The average yield was 39.9 gal. of 95 per cent alcohol per ton of dry wood, the largest yield ever obtained from any wood. The importance of this work to the paper maker is obvious, since by extracting the chips with water before pulping, an easily convertible sugar may be obtained.

A discussion as to the structure of celluloses from different sources was brought forth by a paper on the "Effect of Concentrated HCl on Different Celluloses," by E. C. Sherrard and A. W. Froehlke. Several cellulose samples from woods and cotton were treated with HCl and the change of angular rotation observed. Curves in which specific rotation was plotted against time show marked differences, indicating differences in the structure of the celluloses.

Additional evidence of differences in the chemical structure of wood cellulose from that of cotton cellulose was offered as a result of investigations by E. C. Sherrard and G. W. Blanco into "Some of the Products Obtained in the Hydrolysis of White Spruce." In this work, the volatile products, the soluble materials and the fibrous residue have all been studied. The best cooking conditions were determined. The yield of volatile acids was found to be 1.9 per cent of the dry wood used, the yield containing four times as much acetic as formic acid. Methods for the identification and determination of various sugars were developed. A yield of furfural was obtained equal to twice the yield of volatile acids.

"Sugar Formation in a Sulphite Digestor," by E. C. Sherrard and C. F. Suhm, discussed the rate of sugar formation during the pulping process and the effect of the formation on the quality of pulp. It was found that the rate of sugar formation is influenced mostly by the temperature and the concentration of free SO_2. Time is also a factor, since prolonged cooking increases sugar production, but at the expense of cellulose.

"The Results of Analyses of Some American Woods," read by L. F. Hawley, presented the work of the Forest Products Laboratory on Western woods as possible substitutes for those species which are becoming scarce. The acetic acid content, pentosane, methoxy and furfural content of eight species was determined. Dr. Hawley also presented some recent results on the distribution of methoxy groups in the products of wood distillation, by L. F. Hawley and S. S. Aiyar.

"The Analysis of Western White Pine and Eucalyptus," by S. A. Mahood and D. E. Cable, gave interesting figures on the yield of acetic acid from the two woods and a comparison of their lignin and alpha cellulose content.

Symposium on Production of Cattle Feeds From Waste Cellulose

A symposium on the production of cheap cattle feed from wood waste brought out some interesting discussion. E. C. Sherrard described the acid hydrolysis of sawdust for production of feed and the experiments of Prof. Morrison of Wisconsin University in substituting this product for barley in the standard cattle ration. Harold Hibbert described the Oexmann process of treating straw with alkali under pressure for the production of a feed which is 75 per cent edible. An improvement over this process is the Beckmann method, by which 100,000 tons of feed was made in Germany in 1918. Chopped straw is treated for 3 hours at 100 deg. C. with a 1 per cent Na_2CO_3 solution. Since no pressure is required, this can be carried out by any farmer and yields a feed which is 75 per cent edible, whereas the original chopped straw was less than 20 per cent edible.

Division of Dye Chemistry

Of the twelve papers scheduled for the Dye Division, only six were read, as several of the authors were not present. R. N. Shreve, secretary of the Division, presided.

Herbert L. Haller's paper on the preparation of phenylglycine ortho carboxylic acid from anthranilic acid and monochloracetic acid was read by Max Phillips of the Color Laboratory, Bureau of Chemistry. The paper discussed the optimum conditions of concentration, time, temperature, ratio of reacting materials and condensing agent as determined by experiment. This process was said to be used commercially in France.

"The Preparation of 7-7′ Di (alpha-hydroxyisopropyl) Indigo" was the subject of a paper by Max Phillips. It described the preparation of a new indigo dye from paracymene obtained from sulphite turpentine. The new dye has a similar absorption spectrum to that of indigo and compares favorably in dyeing properties. It is soluble in most organic solvents. Thus far the yield obtained is only about 15 per cent theoretical.

"The Influence of Sulphur on Colors of Azo Dyes" was the subject of a paper by W. R. Waldron and E. Emmet Reid, read by the latter. Dr. Reid exhibited several series of wool samples in connection with his talk, showing the effect of sulphur in the sulphide and sulphone condition in comparison with the sulphur-free base. Thirty different bases containing sulphur in various positions and associated with various alkyl and aryl radicals were prepared, diazotized and coupled with dye intermediates. It was found that sulphide sulphur

deepens the color, but the sulphone group gives a color even lighter than that of the base.

"Uses of Paratoluenesulphonyl Chloride in the Manufacture of Dyes and Intermediates" was the title of a paper by Jules Bebie, Monsanto Chemical Co. This substance is a byproduct in the manufacture of saccharin. One of its derivatives, chloramine-T, is an excellent germicide. It can be used as a component or part of a component for the production of various classes of azo dyes and in combination with azo dyes containing hydroxyl groups to make the resulting dyes fast to alkali and soap.

"The Application of the Direct Dyes in Coloring Paper," by Walter C. Holmes, E. I. du Pont de Nemours & Co., was read by title by A. E. Houlehan. The paper discusses the ineffectiveness of customary trade practice for sized papers due to the formation of considerable proportions of aluminum lakes of undesirable characteristics. A large range of attractive shades of superior fastness are said to be possible by judicious employment of copper lakes of various individual dyes and combinations.

"The Analysis of Beta Naphthylamine," by Henry R. Lee and D. O. Jones, was read by the former. Four methods for this determination were discussed, with advantages and comparative results. Melting point curves for beta naphthylamine with each of its usual impurities were given.

Division of Organic Chemistry

A most ambitious program of thirty-odd papers was scheduled for the Division of Organic Chemistry and long sessions were held on both Wednesday and Thursday. The chairman, Dr. Hans T. Clarke, had not recovered sufficiently from his recent illness to attempt the long trip to Birmingham, and in his absence the meetings were conducted by Prof. Frank C. Whitmore, secretary of the Division. Unfortunately lack of space in this issue precludes the detailed mention of the many interesting and valuable papers which were presented before the organic chemists, but it is at least worth while to comment on an important innovation introduced by this Division. On March 25, well in advance of the Birmingham meeting, Dr. Whitmore sent a complete set of abstracts of all papers to each member enrolled in the Division. This action not only stimulated the interest of organic chemists in the work of the Division but afforded an opportunity for those unable to attend the meeting to follow its progress. It is the belief of the Division's officers that only a small proportion of the organic chemists of the country are now enrolled in the Division of Organic Chemistry, and it is suggested that those interested in receiving copies of abstracts communicate with Dr. Whitmore, of Northwestern University, at Evanston, Ill.

Division of Rubber Chemistry

It will be recalled that at the New York meeting the Division of Rubber Chemistry went on record as favoring the formation of a central research laboratory under the direction of the Rubber Association of America. After due deliberation the Rubber Association has decided that the time is inopportune for such an undertaking and is, therefore, taking no action at present.

The Geer age test was formally adopted as the standard age test of the Division. The feeling was expressed by Mr. Boggs and others that the present specifications containing limits on extracts, total and free sulphur, etc., are restricting development. Physical and life tests were considered much more reasonable. The Rubber Division methods of chemical analysis are now ready for publication and will be taken up for approval at the September meeting. The physical testing committee has prepared agenda and will report at the September meeting.

Internal Mixers

R. P. Dinsmore reported on an elaborate series of experiments on internal mixers performed at the Goodyear Tire & Rubber Co. One gathered from his paper that the results have not been entirely satisfactory. He met with least difficulty in low-grade compounds. He mentioned the interesting observation that rubber which is plasticized by heat at high temperature, such as is obtained in the internal mixers, has a greater recovery—that is, is stiffer—when cooled than stock broken down to the same apparent plasticity on the mill.

Thermal Properties of Rubber and Rubber Pigments

Extensive experiments to determine the specific heat and conductivity of rubber fabric and were summarized by Ira Williams in a paper on "Thermal Properties of Rubber and Rubber Pigments." This matter is of great importance. Mr. Williams' tables will be found below.

THERMAL CONSTANTS OF PIGMENTS

Pigment	Sp.Gr.	Sp.Ht.	Conductivity (C.G.S. Units)
ZnO	5.5	0.125	0.00166
Red oxide	4.7	0.160	0.00132
$MgCO_3$	3.0	0.303	0.00103
Lithopone	3.95	0.115	0.00094
Whiting	2.68	0.201	0.00084
Cord fabric*	1.5	0.324	0.00082
Blanc fixe	4.35	0.114	0.00078
Gas black	2.0	0.204	0.00067
Dixie clay	2.6	0.200	0.00058
Talc	2.70	0.209	0.00058
Litharge	9.25	0.052	0.00051
Rubber, smoked sheet crepe, etc., including cured	0.92	0.502	0.00032
Golden antimony	3.20	0.025	0.00021
Sulphur	2.00	0.175	0.00012

Physical Properties of Rubber Compounded With Light Magnesium Carbonate

H. W. Greider made a study of the physical properties of rubber compounded with light magnesium carbonate. The dolomite deposits of Pennsylvania furnish an adequate supply of raw materials. Best grades of precipitated carbonate approximate $11MgCO_3 . 3Mg(OH)_2 . 11H_2O$. The water is probably chemically combined. No decomposition below 265 deg. C. The light magnesium carbonate has a specific gravity of 2.18. Extensive compounding data show 9 volumes magnesium carbonate to 100 volumes rubber to be the optimum ratio. This corresponds to 21 parts by weight on rubber. Magnesium carbonate ranks as a filler between zinc oxide and carbon black. The high set imparted will restrict its use. Surface aging of stocks high in carbonate is bad, due probably to crystals of carbonate. Mixtures of carbon black and magnesium carbonate, 6 volumes and 3 volumes, respectively, to 100 of rubber, show greatest stiffening action. The combination of zinc oxide and magnesium carbonate is the best aging. Work is going forward on producing an amorphous magnesium carbonate which the author hopes will overcome the high set.

Stress-Strain Curves

W. B. Wiegand presented some excellent ideas on a standardized graph for stress-strain curves, etc., for the purpose of making the work of the various investigators more comparable. This matter was referred to the physical testing committee.

Relation Between Chemical and Physical State of Cure

The relation between chemical and physical state of cure of rubber vulcanized in the presence of certain organic accelerators was discussed by Norman A. Shepard and Stanley Krall. Their paper dealt with the old question of the relation between physical properties and coefficients of vulcanization. Experiments were performed with several common accelerators. The accelerator ratios were varied until the stress-strain curves at a definite cure—namely, 60 minutes at 141.7 deg. C.—passed through a definite point. In this manner they secured the same depolymerization from heat in all cases. It was found that equivalent stress-strain curves under these conditions were given with the following compound:

Base Stock:	
Rubber	48
Zinc oxide	48
Sulphur	3
Equivalent accelerator ratios:*	
Hexamethylenetetramine	0.5
Paranitrosodimethylaniline	0.25
Aldehyde ammonia	0.75
Thiocarbanilide	1.5

*The amounts of accelerator shown were added to four different mixes of the base stock.

The coefficient of vulcanization was obtained as follows:

Extraction 16 hours in an Underwriter's flask with acetone; 5 hours' extraction with alcoholic potash; 16 hours' extraction with alcohol followed by treatment with an ether hydrochloric mixture, as according to Stephens, followed by long extraction with water to remove all soluble sulphates. Sulphur was then determined by the Watters and Tuttle method. Coefficients of vulcanization were as follows: 0.87 with hexa-, 1.03 with paranitroso, 0.98 with aldehyde ammonia, and 1.38 with thiocarbanilide. The authors therefore conclude that vulcanization coefficient has no relation to physical properties and that the various accelerators have a specific action other than sulphur addition.

Recent Developments of the Chemistry of Rubber

Dr. Geer repeated his very interesting talk before the Rubber Division.

Approximately thirty-five members attended the meeting of the Division.

Division of Water, Sewage and Sanitation

Prof. Edward Bartow, of the State University of Iowa, read a paper prepared by himself and two of his associates, M. E. Flentje and W. U. Gallaher, discussing the effect of temperature on the rate of reaction in water softening by the lime-soda ash method. Although the reactions in this process are well known, the effect of heat has not been definitely established in the literature. Furthermore, the manufacturers of hot lime-soda water softeners have made public but little of their own data on this subject.

The experimental work described in this paper was conducted on the deep-well water of Iowa City, which has a mineral acid hardness around 95 p.p.m. A special apparatus was developed which could be heated electrically to a constancy of 0.5 deg. In addition to temperature variations, the amount of lime was varied to ascertain the effect of mass action on the process. It was used both in excess and in lesser quantity than that theoretically required for complete softening.

The principal conclusions of the authors were as follows:

1. The rate of reaction increases with lime provided sufficient sodium carbonate is added to neutralize the non-carbonate hardness.
2. The rate increases greatly with the rise in temperature; the greatest relative increase in rapidity probably occurs in the 18-20 deg. C. rise above normal.
3. Completeness of reaction also increases with temperature and the first 18-20 deg. is likewise most effective. The time of reaction is cut from 4 hours to 30 minutes. At a rise of 40 deg. the reaction is almost instantaneous—in fact there would appear to be no justification for heating above 65 deg. C.
4. With increasing temperature a small decrease was noted in the amount of lime required for softening.

Mechanism of Iron Removal

Prof. A. M. Buswell, chairman of the Division, gave an interesting discussion of the mechanism of iron removal. Our prior knowledge of iron in water has been very ably summarized in a long paper presented by Robert Spurr Weston[1] in 1909 and Dr. Buswell limited his comments to more recent developments. In connection with the two usual methods of removal—viz., filtration and aëration followed by filtration—it was pointed out that detention after aëration is not particularly effective, since even 6 hours fails to remove more than 25 per cent of the Fe. The probable explanation is that the iron is still in colloidal form. Gravel filters, probably by adsorption, will remove 25 per cent and thus lessen the load on slow sand filters.

The fact that lime will remove iron, while alum is not so effective, can be explained on the basis that the $CaCO_3$ resulting from the lime forms negatively charged particles which attach themselves to the colloidal suspension. Alum, on the other hand, forms positive colloids which do not exhibit the "attaching" power of the $CaCO_3$. This theory is confirmed by the fact that other negatively charged particles such as clay and diatomaceous earth act in a manner similar to lime.

Dr. W. W. Skinner, secretary of the Division, summarized two papers from his laboratory at the Bureau of Chemistry. The first, by J. W. Sale, discussed the determination of specific gravity of mineral waters by calculation. The second, by Dr. Skinner and Messrs. Badger and Sale, outlined a number of interesting reminiscences regarding the unusual compositions noted in certain bottled mineral waters.

The Value of the p_H Determination in Water Treatment

Chairman Buswell also summarized a paper by Dr. W. D. Hatfield on the application of p_H value to the operation of a filter plant. After reviewing the various methods for determining the hydrogen-ion concentration, the author concludes that the colorimetric methods

[1] "Purification of Ground Waters Containing Fe and Mn," *Trans.*, Am. Soc. C. E., vol. 64, pp. 112-207 (1909).

are more satisfactory than the electrometric. He has found the buffer solutions of Clark and Lubs to be the most useful. Among his principal conclusions are that the amount of alum used is dependent upon the buffer value of the water, which in turn is roughly dependent upon the methyl orange alkalinity. Coagulation begins at a p_H value of 7.8 and in the summer months is satisfactory at around 7.6. The most efficient results at the Highland Park (Detroit, Mich.) filter plant over several months demonstrated an optimum value of 7.3. In the discussion of this paper it was pointed out that these conclusions are of course applicable only to the single plant studied.

Dr. Buswell, in a lucid discussion of the chemical equilibria in the coagulating basin, drew a chart which showed the striking importance of the hydrogen-ion concentration. It was made very evident that all of the basic reactions in water treatment are more or less dependent upon this factor. Much of the work which has been done recently, especially by the engineers, to simplify water chemistry has been at the expense of neglecting many of the underlying fundamentals such as are considered in Dr. Buswell's paper.

The Smoker

On Tuesday evening the members of the Society were the guests of the Alabama Technical Association at a smoker given at the Southern Club of Birmingham. The hosts, who are the Alabama members of the leading national engineering societies, provided an interesting program of music, vaudeville and good fellowship. Perhaps the most popular as well as unusual feature of the program was the characteristic negro melodies sung by a chorus from the Colored People's Sixteenth Street Baptist Church.

Excursions to Plants

The Tennessee Coal & Iron Co.'s Special

Through the energetic efforts of the Alabama Section's committee on excursions, of which J. R. Harris was chairman, and through the courtesy of the Tennessee Coal, Iron & Railroad Co., about two hundred members were enabled to visit the numerous industrial plants clustered in the Birmingham Valley. A special train was furnished which left Birmingham at 9 a.m. on April 7 and carried the members to the iron, coke, steel and wire works and to the iron and coal mines, stopping at each point of interest long enough for a brief inspection trip through each plant.

Although any of the plants visited would have offered enough of interest to consume several days of inspection, the well-planned excursion served admirably to give the members a birdseye view of this industrial center of the South. In this richly endowed valley were seen iron and coal mines, limestone quarries, gravel beds and byproduct coke plants within a radius of a few miles. the longest rail haul required for any of the raw materials of the steel works being 14 miles. The morning of the trip included stops at the Ensley plant of the Tennessee Coal & Iron Co., where the blast furnaces and open hearths were seen in operation, a visit to the Bessemer rolling mills, which were rolling out steel rails, and stops at Ishkooda iron mine and the coal mine at Edgewater. Arrived at Bayview, the members were greeted by the strains of "Dixie," while on the slope above a beautiful lake were found tables loaded down with barbecued meat and Southern delicacies and even a mysterious tent which was rumored to contain a high explosive, manufactured from corn in the nearby hills of Shelby county.

After a hearty luncheon, the special train proceeded to the T.C.I. byproduct plant, which was thrown open for inspection; thence to the Fairfield blooming mill, where the plate and structural mills, tie plate department and car plant were seen. The final stop was made at the American Steel & Wire Co. and opportunity was afforded for seeing the drawing of wire, the weaving of wire fences and the manufacture of wire nails. Not one of the tired chemists that tumbled from the train at 6 o'clock in Birmingham but had conceived an admiring appreciation of the industrial activity of this section.

Additional opportunity was afforded on Saturday, April 8, for visits to the American Cast Iron Pipe Co. and the fertilizer and cement plants in the vicinity of Birmingham. Great credit is due to the local committees, not only for the well-planned trips but for the excellent arrangements for meeting places, entertainment and transportation. The executive committee was composed of J. F. Carle, chairman; Theodore Swann, C. N. Wiley, M. Kuniansky, J. T. MacKenzie, J. R. Harris, H. S. Geismer and A. K. Boor.

Visit to Muscle Shoals

A desire on the part of many to visit the Muscle Shoals nitrate plants and power site resulted in arrangements being made for special sleepers leaving Birmingham Friday night and arriving at Sheffield Saturday morning. About fifty made the trip, the delegation being divided at Sheffield into two parties, those who intended to spend the entire day there and those who wished to leave early in the afternoon. Members of the Sheffield Chamber of Commerce very kindly furnished automobiles and conducted the parties through plants 1 and 2, and the steam power plant on the Tennessee River, which were thrown open for the occasion. In the afternoon the visitors were afforded the privilege of a detailed and extremely interesting inspection of Wilson dam under the expert guidance of Colonel Weeks, officer in charge of construction.

The two crowded days of excursions and sightseeing brought a successful meeting to a fitting close. Each homeward-bound member carried away a jumble of pleasant impressions — the beauty and hospitality of Birmingham, her remarkable industrial activity, the magnitude of the Muscle Shoals project, the solid support which Henry Ford has in the South, the hospitality which was manifested everywhere and recollections of friendship renewed and made.

Au revoir, Dixie, and thank you!

E. H. H. C. P. Wik Kirk Buck Mack
"CHEM. & MET.'S" DELEGATION AT BIRMINGHAM

Chemical Schedule of the Senate Tariff Bill

A Study of the Changes Proposed in the Fordney Measure Which Will Most Affect the Chemical Industries—Provisions for Flexible Tariff and Temporary Extension of Dye Embargo—Tabular Comparison of Rates With House Bill and Existing Law

AFTER nearly 9 months of study and preparation the majority members of the Senate Finance Committee have reported their long-expected revision of the permanent tariff bill. Although many important changes have been made in the draft approved by the House, a long and bitter fight is in prospect before the bill is finally written on the statute books. A number of the crudities and rough spots in the Fordney measure have been smoothed over and notable improvement made in the elimination of certain provisions of questionable merit.

As in past tariff laws, ad valorem rates in the Senate bill are based on the foreign value of imported merchandise. The American valuation plan as embodied in the bill passed last July by the House was abandoned because of the limited number of exactly comparable domestic and foreign products and the difficulty and probable litigation involved in defining comparability to the satisfaction of importers, domestic manufacturers and customs officials.

As a substitute measure the committee has incorporated provisions for a flexible tariff and proclaimed American valuation such as had been recommended by President Harding. The elasticity in the tariff has been provided by giving the President authority to increase or decrease the rates not exceeding 50 per cent, if after investigation he finds such action is necessary. The President is also empowered to change the basis of valuation on certain items from the foreign value to the value of the domestic article; to impose penalty duties and prohibit the importation of particular goods; and to impose additional retaliatory duties against any country which discriminates against us.

Embargo on Dyes and Synthetic Organic Chemicals

So far as the chemical industries are concerned the outstanding feature of the tariff bill is the extension for 1 year of the dye and chemical control provisions of the emergency tariff act. A last-minute change before the bill was reported provided that the President could extend the embargo for an additional year if it should be found necessary. Chairman McCumber, in the report which accompanied the bill, gives the following explanation of the committee's attitude toward the domestic dye and synthetic organic chemical industries:

> It was found that the rates provided for dyes and coal-tar chemicals, after the limited embargo provisions covering these products had been eliminated on the floor of the House of Representatives, were wholly inadequate to protect the domestic industry.
>
> It is common knowledge that Germany had a monopoly of the world's trade in dyes prior to the war. Although our domestic industry has made great strides during and since the war, when these products have been admitted to the United States only under license, as provided by the emergency tariff act of May 27, 1921, and although our industry is capable of supplying between 85 and 90 per cent of the quantity required by domestic consumers, it has not attained a point of efficiency of manufacture where it can hope to compete with the well-organized industry which exists in Ger-

RATES OF DUTY ON IMPORTANT CHEMICALS IN SENATE BILL COMPARED WITH THOSE IN HOUSE BILL AND UNDERWOOD-SIMMONS ACT

many. Your committee has reached the conclusion that no rates in American tariff history would be adequate to protect this industry.

Your committee therefore recommends that the provisions of the emergency tariff act relating to dyes and synthetic organic chemicals be extended for a period of 1 year after the tariff bill becomes a law. The President is also authorized, if upon investigation he ascertains that the rates specified upon coal-tar intermediates and dyes do not equalize the differences in competition here and abroad, or if he ascertains that an industry in the United States is being or is likely to be injured by reason of the importation of like intermediates or dyes into the United States, to issue a proclamation stating such fact and to continue the dye and chemical control act in force for a further period not to exceed 1 year. In addition, the following rates of duty on these products are proposed: 50 per cent plus 7 cents per pound on intermediates and 60 per cent plus 7 cents per pound on finished coal-tar products.

Under the administrative provisions previously referred to, the President is given authority to change the basis of these rates to the American values of similar or competitive articles and also to increase or decrease these rates as much as 50 per cent if such action is found to be necessary. The extension of the dye control provisions for 1 year, or 2 years if necessary, will give the President ample time to investigate conditions in the dye industry and to ascertain what changes in rates and methods of valuation are necessary in order that all branches of the organic chemical industry may become firmly established in the United States.

The inequalities between the rates on citrate of lime and citric acid were adjusted by increasing the duty on citric acid from 12 to 18 cents per pound and decreasing

the rate on citrate from 7 cents to 6 cents per pound. The duties on lactic acid and oxalic acid have been increased considerably over those in the House bill. The rates on butyl alcohol and competitive products were more than cut in half by the Senate Finance Committee. Both crude and ground barytes received substantial increases and additional compensatory duties were imposed on the various barium chemicals. In the case of mercurials, too, it was necessary to increase the duty in order to compensate for the increase in the rate on quicksilver, which had been changed on the floor of the House. The duty on chalk was radically increased—from 15 to 35 per cent—presumably to take care of the highly purified, chemically refined chalk.

Changes From Ad Valorem to Specific Duties

In a number of places throughout the chemical schedule it will be observed that specific duties were substituted for the ad valorem rates of the House bill. This was usually done in the case of definite chemical compounds in which there is but little variation in the grades or qualities ordinarily used in commerce. Another factor which no doubt prompted many of these changes was the relatively greater stability in prices at present than at the time the House bill was framed.

The duty on natural dyeing and tanning extracts has been more than doubled over that in the House draft. A new classification covering vulcanized or hard fiber has been inserted to provide for cellulose products made by treating cellulose with zinc chloride to hydrolize it and then after dehydration, molding the material by pressure. The glue and gelatin paragraph has been entirely rewritten and edible gelatin has been separated from other forms of glue and gelatin. In the case of the technical products the separation is on a price basis —the dividing line being at a value of 40 cents per lb.

Vegetable Oils

A heavy duty was placed on cottonseed, soya bean, coconut and peanut oils, but by means of an important proviso these oils can be imported duty free under bond for use in the manufacture of products unfit for food. This is practically equivalent (except in the case of peanut oil) to putting them on the free list. The duty on castor oil has been reduced and that on alizarin assistants increased from 25 to 35 per cent. One interesting and highly important change has been in the case of tapioca and sago, which were transferred from the free list and given substantial duties under the agricultural schedule.

The paragraph on soap was changed materially and the language of the old 1909 provision accepted. This provides somewhat higher duties but will also give the customs officials a chance to distinguish between "perfumed" and "unperfumed" toilet soap.

Potash and Cyanide Tariffs

Fertilizer materials remain dutiable, although the rate on ammonium sulphate was reduced from $\frac{3}{5}$ to $\frac{1}{4}$ cent per pound. Chilean nitrate, however, continues on the free list. The sliding scale of duties on crude potash salts—viz., 50 cents per unit for the first 2 years, 40 cents for the third, 30 for the fourth, 20 for the fifth, and thereafter duty-free—was continued in the Senate bill, although a number of slight reductions were made among the refined potassium salts.

The results of one of the most interesting of the tariff battles in the chemical schedule is found in the new paragraph 33a, which provides a 10 per cent duty on potassium and sodium cyanides. This may be said to represent a compromise between the demands of the domestic producers and those of the important consuming interests.

Paragraph 5, the important "catch-all" or "basket" clause of the chemical schedule, which includes "all chemical elements, salts and compounds" not elsewhere specially provided for, carries a duty of 25 per cent ad valorem. This is the same as in the Payne-Aldrich tariff of 1909 and is an increase of 5 per cent over the rate in the corresponding paragraph of the 1913 tariff.

Research Develops New Concept of Soils

Investigations by the Bureau of Soils of the Department of Agriculture have resulted in the announcement of an interesting new conception of the nature of soils. A colloidal material, quite different in nature from the mineral particles and organic matter which are generally believed to make up the whole of the soil, has been isolated from a number of different soils and has been dubbed "ultra clay." It seems to constitute a fundamental part of the soil. Studies of the behavior and properties of the colloidal particles that make up this ultra clay are giving a new concept of the soil, and it is predicted that these researches will throw fresh light on many soil problems.

Ultra clay is described as a gelatinous material which shrinks greatly on drying and has a high absorptive power for water, ammonia, salts and dyes. At the proper moisture content it may have a binding power far greater than portland cement. At other moisture contents it is highly plastic. In short, this material has in an exaggerated degree most of the properties characteristic of the soil as a whole.

Chemically, ultra clay appears to be chiefly a gelatinous silicate of aluminum with varying amounts of ferric hydroxide, silicic acid, aluminum hydroxide and organic matter, in a colloidal condition. These substances exist in such a fine, or colloidal, state of subdivision that when the material is shaken up with water a permanent, opalescent suspension is obtained and many of the individual particles appear under the ultramicroscope only as points of light in active motion. In the presence of certain salts the colloidal particles coagulate, forming large aggregates which readily settle out.

The Electric Resistance Furnace in an English Brass Foundry

A month's test was recently conducted to determine the utility of a Baily 1-ton nose-tilting type furnace in one of the oldest brass-rolling mills in England. The test charges consisted of cartridge shells and rolling mill scrap, pouring 60-40 brass into round billets, strip molds and condenser plates.

In the test on round billets, 3 in. to 6 in. in diameter, operating the furnace continuously for thirty-one heats, 50 hours was consumed in melting and a total of 48,608 lb. of brass was poured. The electrical energy consumed was 306 kw.-hr. per ton of metal melted.

With a similar charge of cartridge shells and rolling mill scrap pouring 60-40 brass into condenser plates weighing 1,700 lb. each eighteen heats required 31 hours and 49 minutes. The total metal melted was 30,744 lb. at an energy consumption of 276 kw.-hr. per ton of metal melted.

By Otto Wilson
Former Chief, Latin-American Division, Department of Commerce

In 1914, when the outbreak of the European war practically shut off the Russian exportation of platinum, the chemical industry and other platinum users of the world turned to the second most important source, the Republic of Colombia. These two countries have furnished practically the world's supply of platinum—Colombia before 1914 being a distant second to Russia, supplying only 6,000 to 15,000 oz. out of a total of 250,000 to 300,000 oz. With the Russian output greatly curtailed, Colombia's proportion, as well as the actual amount produced, increased rapidly. In 1917 the estimated production of Colombia was 32,000 oz. and that of Russia 50,000; in 1918 the figures were 35,000 oz. for Colombia and 25,000 for Russia; in 1919 Colombia produced about 35,000 oz. and Russia 30,000; and in 1920 the two countries were about equal with 35,000 oz. each. These figures, of course, especially as regards Russia, represent only broad estimates.[1] Our imports from Colombia in 1920 were 29,853 oz., and in 1921 31,840 oz. There is reason to believe that with more intensive mining operations the South American country may in time lead the world as a platinum producer, even with a normal Russian output.

Colombian platinum is derived entirely from placer operations in the sands and gravel of the rivers of the western part of the country, from the Ecuadorian border to the headwaters of the Atrato River. The principal stream, so far as known deposits are concerned, is the Condoto River, a tributary of the San Juan. Most of the platinum has heretofore been recovered by natives, but dredging operations, backed by extensive British and American capital, are now being carried on. The South American Gold & Platinum Co. has two dredges working on the Condoto River, and is preparing a third which will be larger than either. One of the dredges produced 6,349 oz. in 10 months in 1919, and in the first 8 months of 1920 worked at a still better rate. The British Platinum & Gold Corporation also has a dredge on the Opogodo River of the San Juan basin. Colombian platinum as it reaches the market consists of 80 to 85 per cent of platinum, a higher proportion than the average, the remainder comprising other metals of the platinum group, notably osmium and iridium.

The platinum deposits are said to extend over the border into Ecuador, but apparently the metal, which is found associated with gold, is not found in important quantities in that country. On the island of Chiloe, off the mainland of Chile, beach deposits of black sand are reported to contain some platinum, but in amounts too small to be profitable so far as present discoveries have disclosed.

Lead and zinc are scattered over many countries of South America, and are smelted in many of them, as also in Mexico. The output of lead (metric tons) in South America and Mexico in recent years has been:[2]

	1913	1914	1915	1916	1917	1918	1919	1920
South America..	2,729	3,145	4,667	4,267	4,571	5,268	7,234	5,510
Mexico.....	62,000	23,598	31,384	19,966	46,612	88,503	78,645	84,200

*For Parts I and II, which discuss other mineral resources of these countries, the reader is referred to Chem. & Met. Eng., vol. 26, Nos. 14 and 15, pp. 631 and 697, April 5 and 12, 1922.

[1]The U. S. Department of Commerce gives the following as a Russian estimate of production in recent years: 1914, 156,960 troy oz.; 1915, 108,489 oz.; 1916, 78,997 oz.; 1917, 98,483 oz.; 1918 (to July 1), 13,166 oz.

[2]Amer. Bur. Metal Statistics Year Book, 1920.

The chief South American lead exports come from Peru, where it is obtained as a byproduct in silver mining or from the ancient slag of the Cerro de Pasco copper mines, which formerly produced silver. The total represents scarcely a third of 1 per cent of the world's output. In the neighboring country of Bolivia there is also a small production, the exports running from 1,000 to 3,000 tons a year. The ore is galena and the only field worked is near the town of La Quiaca, on the Argentine border. This ore is generally exported through Buenos Aires. Argentina has numerous deposits of lead in the same districts in which copper is found; in fact, the sulphides of the two metals often occur together. Working heretofore has been for the purpose of obtaining silver, with which the lead is often associated. All deposits are lode deposits.

In the provinces of San Juan, Mendoza, Neuquen and Cordoba there has been more or less exploitation and development of the argentiferous galena veins, but in other provinces containing apparently abundant deposits, among which are Salta and Jujuy, there has been little production. Lead has been reported from several localities in Brazil; Chile has a small output from the silver mines; Colombian lead ores have been found in the departments of Caldas, Santander, Boyaca and Cundinamarca, and Venezuela has lead deposits in the states of Lara and Tachira. Galena deposits in the State of Minas, Uruguay, have been worked occasionally.

Zinc in the form of sphalerite is associated with lead and other ores in several countries and large deposits are said to exist in the Yauli district in the Province of Junín in Peru. The general lack of transportation facilities, however, has prevented development or active interest in most of these sources.

Mexico has extensive deposits of both lead and zinc. Lead smelting is an important industry, particularly in the Monterey district, and the annual pig-lead production of 50,000 to 125,000 tons makes Mexico one of the notable sources of the world's lead supply. The chief states producing lead are Chihuahua, Durango, Sonora, Nuevo Leon, Coahuila, San Luis Potosi and Zacatecas. There is apparently a large potential output of zinc in Mexico, and in the Piedras Negras district, when prices are favorable, production of calamine ore is carried on at the rate of 10,000 tons a month. The total Mexican production in recent years has been at the rate of 11,000 to 45,000 tons a year.

In Central America, Guatemala has deposits of lead, zinc and copper near Concepcion, and the International Railways has shipped several hundred tons of calamine ore and lead carbonates, together with concentrates.

Bauxite Deposits in the Guianas

While Brazil is said to have deposits of ferruginous bauxite among the surface iron ores of Minas Geraes, and occurrences are reported in Venezuela, Colombia and Ecuador, the only section of Latin America where the mineral is known to exist in large quantities is the Guianas. Because of lack of settlement and of transportation facilities the beds have not been fully mapped out, but they are said to be of great extent, and a former Governor of British Guiana has declared that the deposits of that colony are probably the largest in the world. The alumina content is very high, analyses showing over 60 per cent. The work of exploiting these deposits was begun in 1913, but during the war there was little activity. In 1917 shipments from British Guiana amounted to 2,070 tons, in 1918 to 4,266 tons, in 1919 to 1,967 tons, and in 1920 to 29,394 tons. Because of lack of a demand in the United States the company working the deposits stopped operations early in 1921. Shipments for the first 5 months of 1921, had, however, amounted to 10,545 tons, against 2,982 tons in the previous year.

Antimony From Mexico, Bolivia and Peru

Mexico, Bolivia and Peru have a place among the antimony-producing countries of the world, but only the first named ranks as an important source. Mining in South America was largely the result of war-time demands. The Mexican ores are mixed sulphides and oxides, containing 5 to 50 per cent antimony, and are found principally in the states of San Luis Potosi and Queretaro, although occurrence is spread widely over the country. Sonora, Guerrero, Durango and Lower California, among other states, have deposits of unknown extent. Production in 1917 is stated to have been 2,646 tons; in 1918, 3,278 tons; in 1919, 470 tons; and in 1920, 1,572 tons.

The Bolivian ore is of high grade, running over 50 per cent antimony, but the visible supply is said to be limited. The country is not an important prospect for the future, although war-time shipments were heavy, rising to 27,414 tons of ore in 1916, valued at $6,614,000. The chief producing district is in the southern part of the Department of Potosi. The Peruvian output has come mostly from the Department of Puno, although Cajamarca, Huanuco, Junín and other departments have deposits and Jeru is considered a source of possible future importance. The ore worked has averaged about 60 per cent antimony. Chile reports native antimony and stibnite in the states of Trujillo and Lara, but there has been no particular development in either country.

Bismuth and Quicksilver

The world's chief source of bismuth is Bolivia, where the ore, consisting of both native bismuth and the sulphide, is found associated especially with tin deposits and also with silver and copper. Production comes mainly from mines at Tasna, Chorolque and Huayna Potosi. Since 1914 exports of bismuth have ranged between 350 tons and 680 tons, valued at $850,000 to $1,600,000. Peru has a single mine, in the Department of Junín, whose reserve is said to be sufficient to supply the world for many years. The ore consists of oxidized bismuth compounds, averaging 3 per cent bismuth. In Chile bismuth has been reported from the Province of Atacama, as a sulphide. In Brazil it occurs

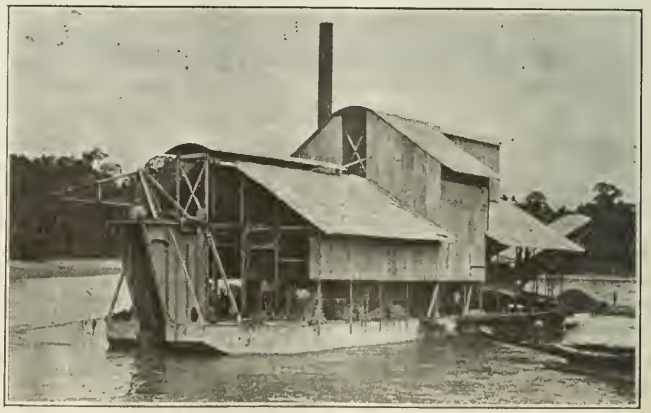

FIG. 20—DREDGE OPERATING IN THE CONDOTO

in the gold mines of Minas Geraes, both as native bismuth and the oxide, and is reported from the State of Rio Grande do Sul. The State of Lara, in Venezuela, has bismuth deposits.

Mercury has been found in several countries—Mexico, Peru, Bolivia, Argentina, Colombia, Chile, Brazil and Dutch Guiana—but in modern times only in the first two has much attention been given to production. The Peruvian mine at Huancavelica was opened about 1566 and the deposits have been worked, though not continuously, since that time. The ore is said to contain an average of 2 per cent mercury. In recent years mining has been suspended, but the owner, a Peruvian, is preparing to reopen the mine, and is driving a 4,000-ft. tunnel and has built two small furnaces. In Dutch Guiana floats of quicksilver are reported from near Marowyne River, and cinnabar is reported in place in one locality. The mines of Mexico, in San Luis Potosi, Guerrero and Durango are producing considerable amounts of quicksilver, the production for the whole country amounting to 163 tons in 1918, 118 tons in 1919, and 77 tons in 1920.

There is no mention of the existence of radium in any Latin-American country except in Brazil, where it is recently reported that the director of a museum in Fortaleza has discovered a deposit of radium-bearing minerals in the interior of the State of Ceara.

Important Non-Metallic Minerals

Mica.—Mica is becoming an important article of export in Brazil and Argentina, and has also been mined to some extent in Guatemala. The Brazilian mica is muscovite, of excellent quality, the masses taken out for export being mostly about 6 in. square, although much larger are often found. Production has so far been confined to four states, Bahia, São Paulo, Goyaz and Minas Geraes. São Paulo shipped 11,000 kilos in 1918. The Argentine mica is found in the Sierra de San Luis and the Sierra de Cordoba, and is said to be of good quality. The deposits are numerous and one Buenos Aires exporter has offered to furnish regular supplies up to 5 metric tons per month. The character and size of the quantities available are unknown, but shipments to Europe from Cordoba have consisted of small sizes of light brown muscovite. The Guatemalan mica is also muscovite, white, amber, green and other colors being found.

Monazite Sand.—In addition to its nitrates and other non-metallic minerals, Latin America has two rich fields, each of which is probably the most valuable of its kind in the world. These are the monazite sands of Brazil and the asphalt lakes of Trinidad and Venezuela. The invention of the gas mantle established the first commercial outlet for monazite, since this mineral is the chief source of thorium and cerium salts, on which the mantles are dependent for their incandescence. Mesothorium, the radioactive element which is coming into increasing importance as a substitute for radium in the manufacture of luminous paints, is also found in monazite. The monazite of Brazil is found both along the seacoast and in the inland river beds, where the action of the water has concentrated the sands formed by the disintegration of the crystalline rocks of the coastal mountains. The occurrence of the monazite in these rocks is too rare to permit profitable working. More concentrated deposits are found at various places along the Brazilian coast between Maranhao and Rio de Janeiro, but only in the states of Bahia and Espirito Santo are they of commercial value. The federal government claims the sands on a strip 33 m. wide, measuring from mean high tide, and these are now being worked under lease. The sands are high in thoria, averaging 4 to 6 per cent, and they can therefore be worked while deposits in our own country lie idle because of low prices. The beach reserves are estimated at 15,000 to 20,000 tons of concentrates. The inland streams apparently furnish the real reserve, the river beds of Minas Geraes, Espirito Santo and Rio de Janeiro having gravels that would probably yield 200,000 tons of monazite. In the last few years exports have gone wholly to the United States, shipments amounting to 1,136 tons in 1917, 500 tons in 1918, 146 tons in 1919, and 1,153 tons in 1920.

Asphalt.—Asphalt deposits, formed by the evaporation of the volatile parts of oil rising to the surface, are found in various parts of Venezuela and on the island of Trinidad. The two great sources of the asphalt of commerce are Trinidad Lake, on the island of that name, and Bermudez Lake, about 30 miles inland on the mainland across from Trinidad. The latter is much larger, covering about 2,000 acres, compared with about 120 acres for the former, but Trinidad has been the chief source of past exports, shipments amounting to 130,000 to 230,000 tons annually as compared with 25,000 to 95,000 tons from Venezuela. Trinidad Lake goes to an unknown depth, boring being difficult because of the fact that the asphalt is in constant slow motion. A depth of 150 ft. has been achieved. Venezuela has other deposits besides Lake Bermudez, several of which have been worked. One is located as far west as the Limon River, 50 miles west of Maracaibo. Cuba and Mexico in the past have also shipped varying amounts of bituminous substances.

Graphite.—Another form of carbon, graphite, is found in several countries, including Mexico, Brazil, Chile, Uruguay and Paraguay. Mexico is one of the chief producers of amorphous graphite for the manufacture of

FIG. 21—CARRYING ORE FROM MINE TO MILL IN MINING DISTRICT OF PERU

pencils, and some crystalline graphite is also reported. Normal production runs for 1,000 to 3,000 tons a year, that for 1917 being 420 tons; in 1918, 6,190 tons; 1919, 4,023 tons; and in 1920, 2,991 tons. The Santa Maria mine, near La Colorado, Cordoba, is the chief producer. Brazil apparently has deposits of an excellent grade of graphite in Minas Geraes and Rio de Janeiro, and also unsurveyed deposits of flake graphite. The former has been used locally for pencil manufacture. Exports amounted to 44 tons in 1918 and 2 tons in 1919. In 1920 there were no exports. In Chile some graphite has been mined at Chehueque, Atacama, but the production has been inconsiderable.

Sulphur.—Several countries have important deposits of sulphur, which are worked for local purposes. Perhaps the most important of these are in Chile in the craters and slopes of the old volcanoes. These deposits are near the nitrate fields and are convenient for the manufacture of the black blasting powder used in nitrate working. Deposits so far worked occur in provinces of Tacna, Tarapacá, Antofagasta, Atacama and Coquimbo, the chief producing district being that of Tocora in Tacna Province. The country's production has gone as high as 10,000 tons a year. Peru has many sulphur deposits, some of them with contents running 30 to 40 per cent sulphur. Venezuela has working deposits of sulphur.

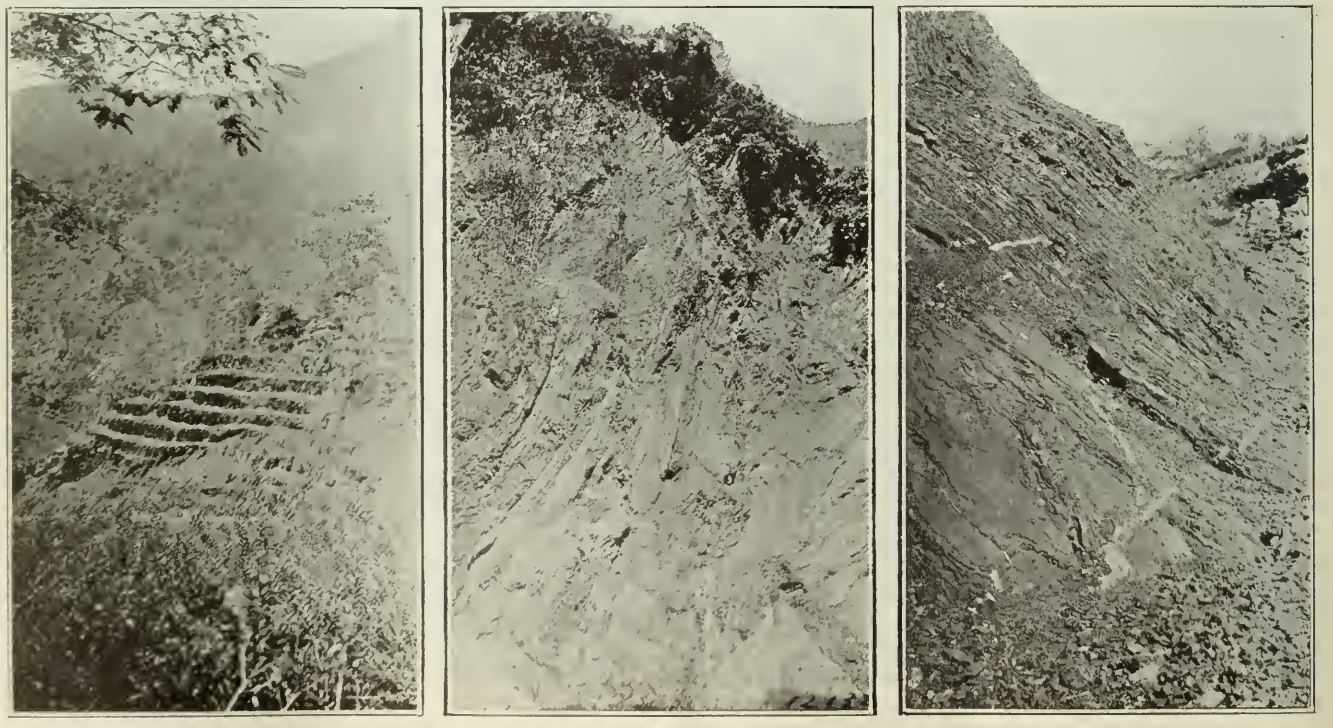
Several localities in Mexico produce sulphur, especially in the states of Durango, San Luis Potosi and Lower California. An interesting deposit worked off and on since the times of the early conquerors is that in the crater of Popocatapetl, where the supply is large, but the altitude makes exploitation expensive. Mexico also has important pyrite deposits, notably one in the State of Guerrero of several million tons, containing 48 per cent sulphur, but there is no production of importance. Cuba has a pyrite deposit near Cienfuegos, and the Andean countries and Brazil, in South America, report its presence in association with more important metals.

Borax.—Chile, Peru, Bolivia and Argentina are the borax countries of South America, the desert regions of northern Chile and one deposit near Arequipa, Peru, being the chief sources. The borates are found in the beds of dried-up lakes called *salares*, some of which contain millions of tons of crude borax. Because of transportation costs very few of these are worked, Chile's production of 40,000 tons annually coming almost entirely from the Saler de Ascotan in Antofagasta. Borax Consolidated, Ltd., a large British company, controls the industry in Chile, Bolivia and Peru, and it can increase its output to take care of any possible demand. The Argentine deposits are in the provinces of Los Andes, Jujuy, Salta and Catamarca. Those worked commercially contain 25 to 40 per cent of boric acid. The sun-dried product runs 38 to 50 per cent anhydrous boric acid. Several hundred tons is mined yearly for local and export purposes, but lack of fuel and transportation facilities makes more extended production unprofitable.

Rock Phosphate.—The chief Latin-American contribution to the world's supply of phosphate rock comes from the Dutch islands of Aruba and Curacao, off the coast of Venezuela. Normally there is a large exportation to Europe. Islands off the coast of French Guiana also export phosphates. Chile and Peru have worked deposits.

Potash.—Chile is the only country having potash deposits of importance, and the industry in that country has not been devoloped. The potash occurs in the *salares*, the two chief ones being the Salar de Pintados and the Salar de Bella Vista, in Tarapaca. Chilean chemists have estimated that these deposits contain over 2,000,000 tons of potash. They are of low grade, however, containing 10 to 15 per cent potassium sulphate (or chloride) and it is yet uncertain whether they can be worked profitably.

In addition to these separate deposits it has been found that some sodium nitrate deposits contain a certain amount of potassium nitrate, and the du Pont com-



FIGS. 22, 23 AND 24—VIEWS OF THE MUZO EMERALD MINES IN COLOMBIA

pany has recovered over 1,000 tons a year of potash in the form of the nitrate. It is claimed that if the du Pont process of separating the potassium from the sodium nitrate were followed at all the nitrate plants, over 100,000 tons of potash could be recovered annually.

Other Undeveloped Possibilities

Other non-metallic minerals are found scattered here and there and give evidence of what may be expected in the way of future development of Latin America's mineral wealth. Magnesite is produced in limited quantities on the island of Margarita, in Magdalena Bay, Lower California, where large quantities in canyon walls and stream beds are reported to be available without mining, and also in Margarita Island, Venezuela, where the ore is of the white amorphous type and occurs in very large deposits. Shipments from both these countries to the United States have been made regularly for several years. Fluorite has been found in many places in Mexico, but has been mined commercially in only one, a rich deposit located near Guadalcazar, in San Luis Potosi. Other deposits promise to become profitable; one of green fluorite in the town of Chalchihuites, in Zacatecas, has been worked to a certain extent. In Córdoba, Argentina, veins of fluorite occur in bands that are colorless, light green, yellow, violet, blue or almost black. Alum and soda are found in the old volcanos in Los Andes, Argentina. Large quantities of alum occur in two craters as clean white compact masses of mixtures of aluminum and magnesium sulphates containing about 20 per cent aluminum sulphate. Mexico is a considerable producer of white arsenic, the output being 2,246 tons in 1919 and 2,183 tons in 1920. The Mapini smelter owned by the American Metal Co. (Ltd.), has a plant with a normal annual capacity of 5,000 tons.

Chile is, of course, the world's largest producer of iodine, which is obtained as a byproduct of the nitrate industry. The largest year's output in recent times was 1,500 tons in 1916, an amount which could if necessary be greatly increased. Asbestos has been reported from Brazil and Uruguay, but apparently the deposits are of no commercial value.

Building stone is plentiful throughout Latin-American countries, but that of Uruguay is perhaps most ornate and best known. The quarries yield both marble and granite, the former ranging through many colors, white, red, pink, gray, black and banded, and providing excellent material for either building or statuary. A number of granite quarries are active, much of the granite being of high grade. Slates of a beautiful color and toughness, very suitable for roofing, are quarried in Uruguay for local purposes. Another notable product of that country found near Conchillas, in Colonia, is a very fine grade of talc which is of such purity that it is used for pharmaceutical purposes as well as in various industries.

Precious Stones

In precious and semi-precious stones Latin-American countries exhibit a wide range. Brazil and the Guianas are well known for their diamonds. Colombia is one of the chief emerald producers of the world. Pearl fishing has for centuries been an important industry of the Caribbean waters off the coast of Venezuela, and in the Pacific along the coast of Mexico, Nicaragua, Costa Rica and Panama. Mexico is famous for its opals. Uruguay has amethysts, agates and other semi-precious stones, and Venezuela has opals, amethysts and garnets.

Distribution of Petroleum Refineries in U. S.

Petroleum refineries in the United States on January 1, 1922, numbered 479 completed plants, with 30 additional plants in process of construction, according to a statistical summary prepared by H. J. Lowe, petroleum economist of the Federal Bureau of Mines. The indicated daily refining capacity of these plants is 2,164,050 barrels of crude oil.

The tremendous increase in the extent of the petroleum refining industry of the country is shown by the fact that in 1914 but 176 petroleum refineries had been completed. Within eight years the number of refineries has been increased by 172 per cent.

Texas at present leads all other states in the volume of oil refining business, with 63 operating plants, with a daily capacity of 345,150 barrels; in addition, the state had on January 1, 46 refineries in shut-down condition, while 9 other plants were being built. Oklahoma is the second state in number of refineries, with 54 operating and 43 shut down; operating plants in this state had a daily capacity of 234,650 barrels. California, with 34 operating plants, was refining 314,360 barrels daily. Pennsylvania had in operation 48 plants, with a daily refining capacity of 114,930 barrels. New Jersey, with but 5 refineries, treats 224,000 barrels of oil daily.

The importance recently attained by the State of Louisiana in this country is indicated by the fact that 14 refineries were treating 114,350 barrels daily, while 11 plants were in shut-down condition. Kansas, with 19 operating plants, was refining 57,650 barrels daily; Illinois, with 12 plants, was handling 62,050 barrels; Wyoming, with 11 plants, was refining 89,900 barrels; and Indiana, with 5 plants operating, was handling 54,300 barrels daily.

Of the 479 completed refineries in the United States, 154 were in shut-down condition at the first of the year. The daily refining capacity of these non-operative plants was 254,610 barrels, or approximately one-eighth of the entire refining capacity of the country. The 30 new plants in process of construction will, it is estimated, add 59,950 barrels to the country's daily refining capacity.

Need for Standardization of Mineral Fillers and Paving Blocks

The broad field of mineral fillers is sadly lacking standardization, according to Oliver Bowles, mineral technologist of the Bureau of Mines. Many users of mineral materials have very indefinite knowledge of their requirements either in color, grain size, grain shape or chemical composition. The standardization of fillers is practically an untouched field, and such standardization accomplished through a comprehensive study of the subject would not only promote better manufacturing processes but would be of material benefit to producers. It is claimed by one producer that the cost of purchasing special screens to satisfy the requirements for odd sizes for one customer destroys most of the profit obtained from grinding roofing grade talc.

Granite paving blocks are manufactured in a great variety of sizes, says Mr. Bowles. Eleven varieties, sold under trade names, were reported in 1917, and many other varieties were sold by sizes only. The State of Maine reported seven different sizes, New York seven, Massachusetts ten and other states a varying number. Undoubtedly some latitude should be permitted in paving block dimensions, particularly in length, but too great complexity is involved when every state or city writes its own specifications.

Aluminum-Silicon Alloys

Aluminum-Silicon Alloys Long Known Are Coming Into Use Because of Superior Casting Qualities—Unique Structural Change Brought About by Treatment of Molten Alloy Improves Physical Properties of Castings—Technical Properties of Alloys Described

By ZAY JEFFRIES
Research Bureau, Aluminum Co. of America

IN VIEW of the fact that aluminum-silicon alloys are now being used to some extent commercially, it is believed that a brief account of their history and characteristics will be of interest to aluminum founders and users of aluminum alloy castings.

Earliest Records

In *Comptes rendus*, vol. 42, p. 49 (1856), is found an account of what appear to be the first alloys of aluminum and silicon, prepared by H. St. Claire Deville and independently by Wöhler. Aluminum-silicon alloys can be prepared in a number of ways. One method described by Wöhler is to fuse a mixture of aluminum and an excess of the double fluoride of potassium and silicon at a temperature above 950 deg. C. in an ordinary crucible. After cooling, there is found in the midst of the fused salt an alloy of aluminum and silicon which contains varying amounts of silicon, depending upon the duration of the heating. Alloys of this nature were used for the purpose of producing pure silicon. This was accomplished by dissolving the aluminum with hydrochloric acid, nearly pure silicon remaining as a residue. In a book "Aluminum and the Alkali Metals" by Charles and Alexander Tessier (1858) the authors state, "As Deville has correctly observed, silicon does not destroy the malleability of aluminum as iron and copper would do." The authors state that the alloy they experimented with contained at least 10 per cent Si.

A rather extensive investigation of aluminum-silicon alloys was made by Adolphe Minet in the early '90s. In a note published in *Comptes rendus*, 1891, p. 1215, he gives the analyses and tensile properties of several aluminum-silicon alloys and aluminum-silicon-iron alloys, in both the cast and forged condition. The alloys were prepared by electrolysis, using a bath composed of sodium chloride (60 parts) and double fluoride of sodium and aluminum (30 parts), to which was added at the moment of fusion alumina (5 parts) and silica (5 parts). He makes the following comment on the tensile results: "The alloys rich in silicon, such as those which contain 8.9 per cent of this metalloid, possess tensile properties superior to those of pure aluminum."

In vol. 1, p. 10, of the *Journal de l'Electrolyse* (1895) results of tests on a large number of Minet's aluminum-silicon alloys are given. One alloy containing 89.8 per cent Al, 1.57 per cent Fe, 8.9 per cent Si, had a tensile strength of 24.300 lb. per sq.in. and elongation of 2.85 per cent as cast. The same alloy in the rolled condition showed a tensile strength of 27,950 lb. per sq.in. and elongation of 9.18 per cent. In this article the following comment is found: "The presence of silicon in aluminum, contrary to the ideas generally spread since Henry St. Claire Deville, does not injure the mechanical properties of aluminum; on the contrary, it gives to it greater hardness and strength without destroying its malleability, and this up to a content of about 10 per cent. Iron, on the contrary, is a harmful element; however, up to a content of 1.25 per cent it increases the strength of aluminum."

The following is quoted from Prof. J. W. Richards' book on "Aluminum," third edition (1896), p. 518: "A small amount of silicon does not appear to be very injurious to the malleability of aluminum, which bears it much as iron and copper do, but over 1 or 2 per cent commences to change its color, makes it harder and especially crystalline so that its malleability is rapidly impaired. The silicon, however, may be present up to even 5 per cent without preventing the use of the metal for castings and articles not to be worked.

"Minet has proved that aluminum may contain even 8 per cent Si and yet be quite strong if the amount of iron present is small; but as the iron increases over 1 per cent the metal becomes worthless."

Studies on the Constitutional Diagram

The first work of consequence on the constitution of the aluminum-silicon alloys is reported by Vigoroux and Arrivaut in "Procès-verbaux de la Société des sciences physiques du Bordeaux," Nov. 21, 1901. Micographs of samples containing 45.5, 25.35, 14.82 (Fig. 1 herewith) and 4.81 per cent Si are given. The authors would place the eutectic composition between 14.82 and 25.35 per cent Si, since their micrographs clearly show excess aluminum in the former and excess silicon in the latter. However, they did not attempt to construct a constitutional diagram.

"Mechanical alloys" of aluminum and silicon are described by Guillet, "Etude Industrielle des Alliages Metalliques," (1906), vol. 1, p. 965, and also in Kent's Mechanical Engineers' Hand Book, 9th edition, p. 398. The following is taken from Guillet: "Among the alloys of aluminum, the ones such as ferro-alumium, ferrosilicon-aluminum and silicon-aluminum, where the silicon is above 10 per cent, are employed in metallurgy. The others, in which the silicon is below 10 per cent, can be employed for mechanical purposes in place of steel on account of their high strength and their lightness." Types are described as follows:

Types	Al	Fe	Si
1	92	1.25	6.75
2	90	0.75	9.25
3	90	trace	10.0

"The highest strength has been obtained with the alloys in which the proportion of iron is quite low and that of silicon about 10 per cent. Above that amount the alloys are crystalline and not of much use. The density of the alloys of silicon is about that of aluminum."

In *Zeitschrift für anorganische Chemie*, vol. 58, p. 154 (1908), W. Fraenkel gives the first constitutional

diagram of the aluminum-silicon alloys. He reports that the alloys form a eutectiferous system with no chemical compounds. The eutectic alloy contains about 90 per cent Al and 10 per cent Si and freezes at a temperature of about 576 deg. C. The alloys were prepared by melting together commercially pure aluminum and Kahlbaum silicon. In *Revue de Métallurgie*, vol. 8, p. 457 (1911), Frilley describes the results of experiments on aluminum-silicon alloys. He calls attention to the harmful effect of high iron on the aluminum-silicon alloys, both as regards the effect on tensile properties and corrosion. He describes an alloy containing 89.18 Al, 10.07 Si and 0.75 Fe as "brilliant crystalline, fusible; can be forged cold." Frilley made aluminum-silicon alloys both by melting mixtures of the two metals and by reducing the oxides of the two metals simultaneously in the electrolytic cell. He states: "All of these [above] alloys were prepared, as we have said, by fusion of aluminum and silicon. It is entirely rational to assume that the results found might be entirely different, if we were able, under other conditions, to bring together some silicon and aluminum for instance in the nascent state, to use an obsolete expression. Now this is precisely what takes place in an electric furnace producing aluminum by electrolysis, and it has been proved that the silicon-aluminum alloy thus obtained has very different properties from those of the metal obtained by melting together the two substances."

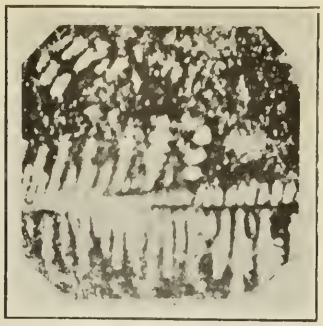


FIG. 1

Aluminum-silicon alloy containing 14.82 per cent Si; fine grained eutectic and excess Al. (Vigoroux). × 35.

Frilley thought that the simultaneous electrolytic production of aluminum and silicon in the form of an alloy might produce a definite compound of aluminum and silicon, not producible except by electrolytic means. He concludes his paper as follows: "In the actual state of our knowledge, we are no better able to produce it than we are able to produce electrolytic silicon, but, as we said above, the problem is the same and everything predicts that on the day when such alloys are realized industry will be in the possession of metal endowed with the most interesting properties."

In 1914 Roberts (*Journal of the Chemical Society*, vol. 105, p. 1383) confirms Fraenkel's constitutional diagram. The eutectic composition was about 90 per cent Al and 10 per cent Si and the freezing point of the eutectic was about 578 deg. C. Alloys used by Roberts were made by the direct fusion of aluminum and silicon.

In 1915, in *Stahl und Eisen*, vol. 35, p. 875, Schirmeister describes experiments on aluminum-silicon alloys to determine the mechanical properties and resistance to corrosion. From his experiments he draws the following conclusion: "Accordingly, aluminum is in general favorably influenced by the addition of silicon, and at the same time the specific gravity is unchanged. The alloys with 5 to 7 per cent Si are best suited to rolling and with 10 to 12 per cent Si to casting." With reference to casting he states: "Contraction and piping decrease with increasing silicon content; at about 11 per cent Si the alloys scarcely pipe at all and above this amount they begin to swell upon solidification."

A general review of the literature on silicon alloys is given by Escard in a book entitled "Aluminum in Industry," published by H. Dunod and E. Pinat, Paris, 1918.

Various Appearances of Silicon

A review of the literature on aluminum-silicon alloys reveals certain discrepancies. Fraenkel and, independently, Roberts report that the eutectic alloy contains about 90 per cent Al. Both these investigators prepared their alloys by the direct addition of elemental silicon to commercial aluminum. Vigoroux and Arrivaut, on the other hand, show by micrograph (Fig. 1) and also mention in the text of their article that in an aluminum-silicon alloy containing 14.82 per cent Si, dendrites of aluminum freeze out first—that is, the aluminum is in excess of the eutectic composition. The silicon in this sample is very finely dispersed. According to Fraenkel and Roberts, such an alloy should contain excess silicon and all the aluminum should be in the eutectic. It will also be recalled that Frilley specifically states that aluminum-silicon alloys prepared by electrolysis of a bath containing both alumina and silica have different characteristics, both physically and chemically, from alloys prepared by the melting together of aluminum and silicon.

These observations have since been confirmed experimentally. When an aluminum-silicon alloy is prepared by direct electrolytic reduction, poured into a containing vessel and permitted to solidify, the silicon is found in the resulting alloy in a finely dispersed state. On the

other hand, in the alloys containing less than 10 to 11 per cent Si prepared by melting together the two elements, the silicon is present in the form of relatively large thin plates. In alloys containing more silicon, the eutectic portion of the silicon is present in the form of relatively large thin plates, whereas the excess silicon appears as more or less equiaxed polyhedral particles, as shown in Figs. 7 and 10.

Fig. 2 shows the normal structure of a sand-cast alloy

FIG. 6—SAME AS FIG. 4, BUT × 250

containing 10 per cent Si, made by the direct melting together of aluminum and silicon. Fig. 3 shows the structure of a sand-cast aluminum alloy containing 10 per cent Si and about 1 per cent Fe, prepared by direct melting. Iron forms a silicide reported to be $FeSi_2$; some of the needles or plates in Fig. 3 are silicide and some are silicon. Figs. 4 and 6 show the structure of an alloy of approximately the same chemical composition—namely, Si 10 per cent, Fe about 1 per cent—prepared by direct electrolytic reduction of silica and alumina. The iron silicide plates are about the same size as in Fig. 3, but the silicon is present in very small particles and the aluminum in dendrites. Fig. 5 shows another electrolytically prepared alloy containing less iron, which has better properties.

Influence of Method of Manufacture

Not only does this process of manufacture greatly affect the condition of the silicon as regards dispersion, but strangely enough it actually changes the composition of the eutectic alloy from 10 to 11 per cent Si in the alloys prepared by direct fusion to 15 per cent Si in the alloys prepared by electrolytic reduction. The amount of excess material of course changes as the eutectic composition changes. The freezing point of the eutectic may be lowered from 576 deg. in the alloys prepared by fusion to about 564 deg. C. in the alloys prepared by direct electrolytic reduction.

Micrographs of the 14.82 and 4.81 per cent Si samples of Vigoroux and Arrivaut show a structure identical with the typical structure produced by direct electrolytic reduction. As previously noted, their alloys were prepared in small porcelain crucibles by melting together commercially pure aluminum and an aluminum-silicon alloy containing about 50 per cent Si, "the immediate product of the reduction of potassium fluosilicate by aluminum." It is evident that their method of preparation produced an alloy having the same structure and therefore the same properties as the alloys obtained electrolytically, a structure evidently caused by the action of the potassium fluosilicate at the elevated temperatures. The correctness of this latter statement is substantiated by the recent work of Pacz, who produced the same structure by the use of compounds of alkali metals with fluorine.

If we refer to the aluminum-silicon alloys made by melting together the two elements as the "normal" alloys and those prepared by the simultaneous electrolytic reduction of alumina and silica as the "modified" alloys, then the alloys prepared by Minet and Vigoroux in 1856 were "modified." A modified alloy may be melted and if it is quickly resolidified it still has the modified structure and characteristics. If permitted to remain in the molten state it gradually passes over to the "normal" condition.

The earlier aluminum-silicon alloys were prepared in different ways, so that some were "normal" and others "modified." Vigoroux and Arrivaut prepared modified alloys; at least the 4.81 and 14.82 per cent Si samples were "modified," whereas Fraenkel and Roberts prepared "normal" alloys. To the best of my knowledge Frilley was the first investigator to differentiate between the two varieties of aluminum-silicon alloy.

Investigations made by the staff of the Aluminum Co. of America accord nicely with those of Fraenkel and Roberts on the "normal" alloys and with Vigoroux and Arrivaut on the "modified" alloys. We find no chemical compound of aluminum and silicon. The modified

FIGS. 7 TO 9—NORMAL ALLOY MODIFIED BY PACZ METHOD

Fig. 8—Same alloy shown in Fig. 7, modified by Pacz process. Eutectic plus excess aluminum. × 50.

Fig. 9—Same as Fig. 8, but × 250.

FIGS. 10 AND 11

"Silumin"; normal and modified structure respectively. × 175. (Metallbank).

alloys and normal alloys show the same type of crystalline silicon by X-ray crystal analysis.

Quite recently A. Pacz of Cleveland (U. S. Patent 1,387,900, Aug. 16, 1921) devised a method of "modifying" the "normal" aluminum-silicon alloys. His process consists briefly in the preparation of the aluminum-silicon alloy by the direct mixture of the two metals, and after the alloy is molten an alkali fluoride—such as NaF, KF, LiF or some other compound containing fluorine and an alkali—is placed on top of the molten alloy. He preferably employs NaF as a base and stirs the pulverized compounds into the molten metal with a carbon rod. After skimming, the alloy is poured and then possesses the properties similar to those obtained by the direct electrolytic reduction of aluminum and silicon. Fig. 7, for example, shows the structure of an alloy containing 12.58 per cent Si made by the direct melting together of aluminum and silicon and cast without any further treatment. Figs. 8 and 9 show another portion of the same alloy after modification in the manner described by Pacz. In the first case, it will be noted that the alloy contains excess silicon plus eutectic in which the eutectic silicon is present in the form of relatively large plates, whereas in Figs. 8 and 9 it will be noted that the alloy contains excess aluminum and the silicon is entirely present in the eutectic in a finely dispersed state.

"Silumin"

Apparently aluminum-silicon alloys treated by a similar process are called "Silumin" in Germany. Figs. 10 and 11 show the structure as published by the Metallbank and Metallurgische Ges.; Fig. 10 is the alloy poured without any treatment and Fig. 11 the alloy poured after the treatment. It will be noted that there is a considerable quantity of excess silicon in the former figure, whereas the latter shows eutectic composition.

Figs. 12 and 13 show the structure of modified aluminum-silicon alloys containing 11.9 per cent Si prepared by Mr. Pacz. The silicon is finely dispersed and there is excess aluminum in the sample. A normal alloy containing 11.9 per cent Si shows excess of silicon.

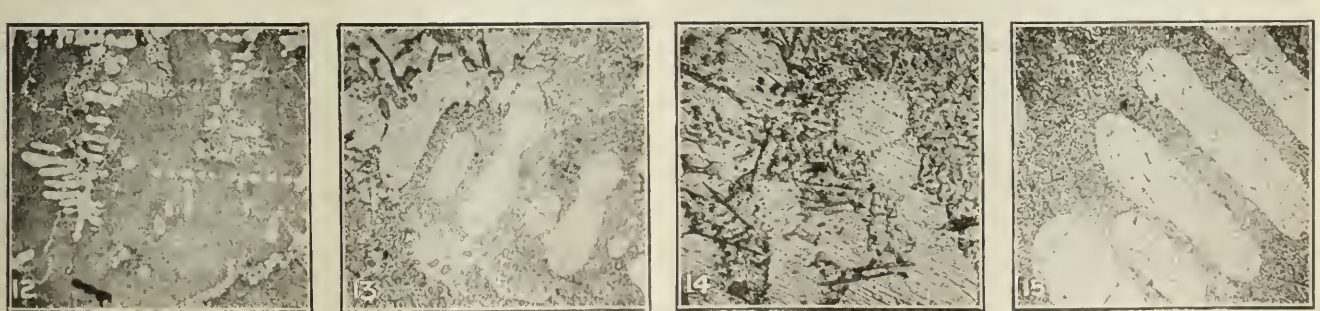
The improvement in physical properties by modification is slight in 5 per cent alloys, but quite marked in aluminum alloys containing between 8 and 15 per cent silicon. Thus the improvement as compared to the normal alloys is more marked the higher the silicon content. With a silicon content of 13 per cent the tensile strength of a sand-cast normal alloy is about 20,000 lb. per sq.in. and the elongation about 2 per cent in 2 in. However, this alloy, modified by the Pacz method and cast in sand, may have a tensile strength of 27,000 lb. per sq.in. with an elongation of 6 or 7 per cent in 2 in. The degree of improvement depends, among other things, on the quantity of flux used. Fig. 14 shows the effect of a small quantity of flux on an aluminum alloy containing 10 per cent Si. It will be noted that the silicon is somewhat refined as compared to Fig. 2. Fig. 15 shows the effect of a greater quantity of flux on the same alloy. Remelting of an alloy modified by the Pacz process, in such a manner as to permit the metal to remain in the molten state for any considerable time causes a reversion to the "normal" condition. The ordinary melting of large batches (10 lb. or more) causes the modified alloy to revert to the normal or nearly normal state.

Physical Properties

The aluminum-silicon alloys are in general resistant to corrosion if the iron content is not excessive. They can be machined, but not as readily as the aluminum alloys customarily used for castings. The density of aluminum-silicon alloys is about 2.65, as compared with about 2.85 for the aluminum-copper alloys.

One of the chief advantages of aluminum-silicon alloys is their good casting properties—a sound "leak-proof" piece may be obtained either in the normal or modified condition.

It will be noted in Fig. 6 that the alloys prepared by direct electrolytic reduction do not show any considerable refinement of the iron silicide plates. This is also true of alloys treated with the Pacz flux. Inasmuch as any considerable quantity of these iron silicide plates will weaken and embrittle the metal, it is essential to keep the iron content low either in the normal or modified alloys. In general it may be said that the lower the silicon content the greater will be the amount of iron permissible in the alloy. With 5 per cent Si, for example, a tensile strength of 18,000 lb. per sq.in. and elongation of 4 to 6 per cent in 2 in. is obtained in the normal state, even with an iron content as high as 0.75



FIGS. 12 TO 15—ALUMINUM-SILICON ALLOYS, MODIFIED BY PACZ METHOD

Fig. 12—Modified aluminum-silicon alloy containing 11.9 per cent silicon. × 40.
Fig. 13—Same as Fig. 12, but × 200.
Fig. 14—Aluminum-silicon alloy containing 10 per cent silicon, partly modified. × 200.
Fig. 15—Same alloy as Fig. 14. Completely modified. × 200.

per cent. This alloy is also machinable, but it does not machine as well as the ordinary aluminum alloys.

Although the tensile strength and elongation of the modified aluminum-silicon alloys are very satisfactory, the yield point is quite low. At a stress of 12,000 lb. per sq.in. the extension is about 2½ times that of No. 12 alloy, which contains about 92 per cent Al and 8 per cent Cu (Metallbank).

Only small quantities of aluminum-silicon alloys are used commercially at present. It seems, however, that they will be found suitable for thin-walled castings and watertight parts. In some places the alloys should be used because of their resistance to corrosion. The modified and normal alloys have about the same advantages with the exception of tensile strength. Many uses will not require high tensile strength, so it is probably safe to predict that the alloys will be used in both the normal and modified conditions according to requirements. When the sand-cast alloys are used in the normal state the silicon content should, in general, be lower than in the modified alloys. In the latter the silicon may be from approximately 8 to 15 per cent and in the former from about 4 to 10 per cent.

Summary

1. Aluminum-silicon alloys were first prepared as early as 1856 by Deville.
2. As early as 1856 Wöhler had prepared aluminum-silicon alloys by fusing together metallic aluminum and an excess of double fluoride of potassium and silicon in an ordinary crucible.
3. As early as 1858 an aluminum-silicon alloy containing approximately 10 per cent Si had been mechanically worked.
4. An extensive study of aluminum-silicon alloys was made in the early '90s by Minet and others, who describe physical properties of a number of electrolytically prepared alloys both in the cast and forged conditions.
5. In 1901 Vigoroux and Arrivaut described the structure of aluminum-silicon alloys containing 4.81, 14.82, 25.35 and 45.5 per cent Si. The 14.82 per cent alloy shows excess aluminum dendrites plus eutectic. The eutectic structure shows a very fine dispersion of the silicon.
6. In 1908 Fraenkel gave the first constitutional diagram of aluminum and silicon, showing that normally the composition of the eutectic alloy is 90 per cent Al and 10 per cent Si and its freezing point is 576 deg. C.
7. In 1911 Frilley discovered that aluminum-silicon alloy prepared by direct electrolytic reduction "has very different properties from those of the metal obtained by melting together the two substances."
8. In the "modified" alloys produced electrolytically the silicon is much more finely dispersed, the eutectic contains a greater quantity of silicon, and the freezing point of the eutectic is lower than in the "normal" alloys prepared by the melting together of aluminum and silicon. The tensile strength becomes greater and the elongation greater as the dispersion of the silicon becomes finer.
9. In 1920 A. Pacz of Cleveland worked out a process of "modifying" the "normal" aluminum-silicon alloys.
10. The modified aluminum-silicon alloys prepared by Frilley's electrolytic reduction method, by Vigoroux and Arrivaut's potassium ferrosilicate method and by the Pacz sodium fluoride method revert to the normal types if permitted to stand in the molten state for any considerable time. Remelting such alloys in large batches and recasting are sufficient to cause the alloys to revert to the normal structure and normal properties.
11. Aluminum-silicon alloys in general are quite resistant to corrosion, if the iron content is low.
12. Aluminum-silicon alloys are machinable, but they do not machine as well as the standard aluminum-copper alloys.
13. The use of processes to modify or disperse the silicon is advantageous chiefly when quantities of silicon above about 8 per cent are used.
14. The chief advantage of aluminum-silicon alloys is in their casting qualities, which advantage is present both in the normal and modified alloys.
15. Iron makes the aluminum-silicon alloys more corrodible and in general weakens and embrittles them.
16. The greater the amount of silicon used the less is permissible iron.
17. It is safe to predict that both normal and modified aluminum-silicon alloy castings will become commercially important.
18. In the modified alloy castings silicon should be from 8 to 15 per cent.
19. In the normal sand castings silicon should be from 4 to 10 per cent according to requirements.

Carbon Black From Natural Gas in 1921

The carbon-black industry showed marked progress in 1921, according to a report of the United States Geological Survey. The estimated total output was 14 per cent greater than in 1920. The following table, which shows the output by states, is based on reports from nearly all the operators:

ESTIMATED PRODUCTION OF CARBON BLACK FROM NATURAL GAS IN THE UNITED STATES IN 1921, BY STATES

State	No. of Plants	Carbon Black Produced — Lb.	Value	Average Price Per Lb. (Cents)	Average Yield of Carbon Black Per 1,000 Cu.Ft. Lb.	Gas Used (Thousands of Cu.Ft.)
Kentucky	2	2,697,075	$215,822	8.0	1.8	1,518,763
Wyoming	2	419,400	37,521	8.9	0.5	869,000
Oklahoma, Pennsylvania, Montana	3	573,225	38,707	6.8	0.9	629,492
West Virginia	21	23,909,000	2,088,000	8.7	1.7	14,312,800
Louisiana	13	31,034,000	2,967,000	9.6	1.0	32,101,800
Total for 1921	41	58,632,700	5,347,050	9.1	1.2	49,431,855
Total for 1920	35	51,321,892	4,032,286	7.9	1.3	40,598,978
Total for 1919	36	52,056,941	3,816,040	7.3	1.0	49,896,235

The average yield of carbon black per thousand cubic feet of gas consumed was slightly lower in 1921 than in 1920, although the efficiency of some of the plants had been materially increased. The yield in 1921 ranged from 0.2 to 3.5 lb., and the maximum was 1.5 lb. higher than the maximum in 1920.

The manufacture of printer's ink consumes approximately from 20 to 25 per cent of the total output of carbon black. About 30 to 35 per cent is used in the rubber industry, where it serves chiefly as a reinforcing agent. A considerable quantity of carbon black is exported to be used for similar purposes abroad but more especially for printer's ink.

The carbon-black industry is an economic factor in the development of new gas fields. This industry can easily be successful in new areas that are sparsely populated and at long distances from markets and that present other unfavorable conditions. Its one requirement is a sufficient supply of natural gas, and in fact an isolated area where there is a sufficient supply of natural gas is an ideal location for carbon-black plants, because there is no domestic demand for the gas. The best illustration of the carbon-black industry as an aid in the development of new and remote natural-gas fields is furnished by the Monroe field in Louisiana. About 5 years ago only a few wells had been drilled in that field in an unsuccessful search for oil. Owing to its remoteness from large cities and communities there is little demand for the gas for domestic use, and this field has therefore been a fertile one for the carbon-black industry, as shown by the quantity produced there.

In the interest of conservation the Department of Conservation of Louisiana has formulated rules requiring the extraction of gasoline from the gas before the gas is burned in the carbon-black plants. As a result most of the carbon-black plants are operated in conjunction with the gasoline plants.

T.A.P.P.I. BANQUET AT THE ASTOR, NEW YORK, APRIL 11, 1922

Seventh Annual Meeting of T.A.P.P.I. Held in New York

Technical Association of the Pulp and Paper Industry Holds Enthusiastic Convention at the Waldorf-Astoria, Pervaded by a Spirit of Optimism for the Immediate Future of the Business, Which Is Emerging From the Period of Depression

FROM the first day of the convention week, April 10, when the technical personnel of the American pulp and paper industry began congregating at the Waldorf-Astoria in New York, a general feeling of optimism was evident.

"The trade is optimistic today, where a year ago it was just the reverse," said W. J. Raybold, president of the American Pulp and Paper Association. "The paper and pulp men have been taking heavy losses, but business is improving and the outlook is more hopeful than in many months."

The convention of the Technical Association was held in connection with the forty-fifth annual meeting of the American Pulp and Paper Association together with other affiliated associations. Sessions of all the sections were held in the Waldorf-Astoria through the week up to Thursday evening.

T.A.P.P.I. re-elected all the present officers—namely: G. E. Williamson, Strathmore Paper Co., president; F. C. Clark, Pejepscot Paper Co., vice-president, and W. G. MacNaughton, secretary.

The high spots in the convention proceedings were the interest displayed in the subject of vocational education and the practical consideration of the technical study of the drying of paper. Prof. David Snedden of Columbia University and J. C. Wright, director of the Federal Board of Education, were the principal speakers on the subject of vocational education, a subject in which the association has been actively interested for some time. In connection with the publication of the third volume of the series of textbooks on "The Manufacture of Pulp and Paper" by the society, the discussion was of especially timely interest.

The problem of the drying of paper is being taken up by the association as a systematic engineering investigation. Besides the paper read by M. B. Littlefield, which is briefly discussed below, F. C. Clark, of the Pejepscot Paper Co., contributed to the symposium on this subject, which was one of the most important which came before the convention. Representatives of a number of paper mills entered the discussion and will continue the study of the problems along the basic lines prescribed.

Sectional Meeting on Soda Pulp and Sulphate Pulp

"Some Factors Influencing the Yield and Strength of Pulp Cooked by the Soda Process" were discussed by Martin L. Griffin. The parallel between the process in cotton textile finishing and reducing wood to finished pulp by the soda process was pointed out. The low yield of the soda process compared with the sulphite and sulphate processes is attributed to the fact that the latter are deoxidizing and therefore act to preserve the strength and increase the yield. Experiments have shown that the addition of small quantities of sulphur increases the yield by its deoxidizing action. A posi-

tive pump to circulate the liquor in either direction and to prevent the direct exposure of part of the chips and pulp to high pressure steam was also recommended as a step to improve yields.

"Recovery and Its Control," by George K. Spence, took up methods of determining the percentage of the original soda used that is recovered and returned to the system. Mr. Spence described the system instituted at Johnsonburg by which the actual recovery for any one period can be calculated and losses located.

Sectional Meeting on Heat, Light and Power

"Modern Lighting for Paper and Pulp Mills," by J. H. Kurlander of the Edison Lamp Works, was illustrated by stereopticon views contrasting the average unsatisfactory lighting practice with up-to-date installations where the proper lamps and reflectors are intelligently used. Mr. Kurlander described a number of typical installations in machine rooms, beater and finishing rooms, and presented curves showing the methods used for correctly spacing and hanging lights for proper illumination.

"The Power Plant of the Paper Industry," by A. G. Darling and H. W. Rogers, pointed out the economies that may be effected by intelligent co-ordination of steam and electric power. The mechanical power requirements of the plant and the process steam requirements were summarized, and upon this basis suggestions were made as to the most efficient machinery for each purpose. Economies that may be effected by the installation of modern hydraulic equipment, electric boilers where hydro-electric power is available and automatic hydro-electric generators were outlined.

Additional emphasis was laid on the use of the last-mentioned apparatus by Horace Drever and Frank Hodson of the Electric Furnace Construction Co. in a paper entitled "The Electric Steam Generator." It is claimed that the use of electricity will save the cost of installation in a little over a year. The generator provides a means of utilizing idle power and thus improving the load factor and occupies small ground space, being simple, reliable and easily controlled.

Sectional Meeting on Mechanical Pulp

"The Efficient Production of Mechanical Pulp," by Adolph F. Meyer of Minneapolis, Minn., discussed the widely different methods of producing mechanical pulp for newsprint and the power consumption in different mills. Mr. Meyer presented curves emphasizing the importance of the proper grinder speed as influencing power consumption and described various installations of governors for this speed control. The shortcomings of the centrifugal pump as a pulp-grinder governor were emphasized and performance records in which the Meyer governor was used were presented in contrast.

"Relative Efficiency of the Automatic Magazine Grinder as Compared With the Pocket Type Grinder" was the title of J. J. Case's paper, which compared the two types of grinders with regard to labor costs, power and maintenance charges. The economical advantages of the automatic magazine type were clearly demonstrated.

The Drying of Paper

"The Drying of Paper," by M. B. Littlefield, took up the problems of drying under the subjects of the properties of paper under heat, proper drying conditions, heat supply and removal of water vapor. Studies of the effects of variations in thickness, furnish, entering and final moisture content and critical moisture content have been made on various grades. The amount of drying accomplished by suction, presses and driers has been determined. Careful studies have also been made of the quantity of heat supplied to the driers and the factors which influence its efficient utilization. Under the topic of the removal of water vapor, the most efficient methods of air circulation were discussed. Drying curves were given to show the rate of removal of water under certain drying conditions, and the effect of steam pressure on rate of drying and consequently on production. Drying ovens, speedometers, pressure gages and accurate records were recommended for efficient drying.

Cotton Linter Pulp

"Stamso-Cotton Linter Pulp," by Stewart E. Seaman of the Stamsocott Co., described the manufacture of this new product, the various grades and qualities and the application of the product in the high-grade paper trade. This pulp may be used in place of rags with a very material saving.

Report of the Sulphite Pulp Committee

The sulphite pulp committee called attention in its report to the need for the development of a more complete knowledge of the constitution of lignin and announced the publication of a translation of the fundamental research of Peter Klason on the constitution of lignin and of Rudolf Sieber's work on the analysis of raw sulphite acid. The report also suggested work on the development of a rapid method for the determination of residual lignin in unbleached sulphite pulp and for the direct determination of combined SO_2 in sulphite acid.

The committee presented its recommendations for specifications for limestone and lime in the manufacture of sulphite pulp.

G. P. Gensberg presented a paper on the "Analysis of Reclaimed Cooking Acid for Sulphite Mills."

The Chemistry of the Sulphite Process

"The Chemistry of the Sulphite Process," by R. N. Miller and W. H. Swanson of the Forest Products Laboratory, presented work of the laboratory in investigating the fundamentals of this process and showed their application in a series of experimental cooks. In this investigation, the total SO_2 content was determined at intervals through the cooks by blowing the cooks prematurely and examining. The apparatus and methods of analysis used were described. It was found that the marked change in chemical composition of the liquor ceased at about the same time that the pulp of superior quality was produced—namely, about the eleventh hour. The rate of removal of lignin was also studied. The importance of the content of free sulphurous acid at the end of the cook was pointed out.

Banquet

Tuesday evening was set aside for the annual feast at the Astor. A large attendance enjoyed an excellent program of speakers, the principal speech being given by Otis W. Caldwell, director of the Lincoln School, New York, on "The Scientific Mind." Judge Charles F. Moore acted as toastmaster.

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Discussion of Disposal of Muscle Shoals Features Joint Meeting of Engineering Societies

Dream cities built up around limitless power resources, fertilizer cheap as dirt and the adaptation of the government nitrate plants for the production of peace-time products were reduced to absurdities by an array of distinguished speakers in a symposium on the Muscle Shoals problem before a joint meeting of the four founder societies in the Engineering Societies Building, New York, on April 14. The discussion was divided into its two logical phases—namely, the project as a power producer and as a nitrate producer. Brigadier-General Harry Taylor, Assistant Chief of Engineers, U. S. A., took up the first topic, and W. S. Landis, of the American Cyanamid Co., discussed the commercial aspect of the second phase, while Major-General C. C. Williams, Chief of Ordnance, U. S. A., spoke on the munitions aspect.

Theodore Nagel, consulting engineer, gave a concise description of the cyanamide process as used in Plant No. 2 which served to make clearer the actual operation of the plant as shown in several reels of motion pictures. The pictures showed the construction and operation of Plant No. 2 and views of the steam power plant on the Tennessee River.

General Taylor presented a history of attempts that were made since 1828 to develop the Tennessee River at Muscle Shoals for navigation and as a power site and gave numerous statistics on construction features of the Wilson dam, with stereopticon views showing details.

W. S. Landis told of the organization of the Air Nitrates Corporation, a subsidiary of the American Cyanamid Co., for the erection of Plant No. 2, one of the largest war operations ever undertaken. The calcium carbide capacity of the plant greatly exceeds the demand of the entire country. The cyanamide produced there is not suitable for fertilizer, said Mr. Landis, and should not be confused with the fertilizer material known under the trade name of "Cyanamid."

The country's maximum peace requirements of ammonium nitrate is 20,000 tons per year. Plant No. 2 has a capacity of 110,000 tons annually. The ammonium nitrate used in industrial explosives is made from the waste acid of the explosive industry and it is doubtful if Muscle Shoals nitrate could be produced as cheaply. The production of "Cyanamid" fertilizer or mixed salts has been suggested. Such plans would mean that the oxidation and absorption plants would be useless and would require the erection of sulphuric acid plants and large bagging and shipping facilities. Only 150,000 tons of ammonium sulphate per year is used in fertilizer and the increase in the production from byproduct plants would seem to indicate that competition in this field would be a losing proposition. Altogether the prospects for the commercial utilization of the plant seem discouraging to Mr. Landis.

Major-General Williams discussed the necessity of munitions for military preparedness in general. The Ordnance Department is not concerned over the process used for the fixation of nitrogen, he said, but it does hope for the development of a commercially practical process as a preparedness measure. He described the serious shortage of nitrate that existed in the Civil War and pointed out that in the World War America depended upon Chile for 75 per cent of the nitrate used and that these fields are being exhausted at the rate of 2,500,000 tons per year. Plant No. 1 at Muscle Shoals, which cost $13,000,000, was stamped as a "failure," but Plant No. 2 operated long enough to prove that it was capable of its full rated production. This plant cost about $70,000,000, but it would have paid for itself in 3 years, had the war continued.

A banker's view of the situation was presented by Francis E. Frothingham, of Coffin & Burr, bankers. This firm has distributed $20,000,000 of Alabama Power Co. bonds and Mr. Frothingham therefore felt qualified to compare the offer of that company with Henry Ford's. While acknowledging Mr. Ford's ability as a manufacturer, the speaker expressed the belief that the same offer from any other source would have been instantly repudiated. He emphasized the necessity for observing the provisions of the federal water-power act and declared that all bids should be submitted on this specification. He characterized as unfair Mr. Ford's failure to denounce the glittering real estate promotion schemes built around the "75-mile city" and the absurd propaganda to the effect that he saved Muscle Shoals from the junk-heap and from exploitation by foreign capital. He compared the details of the two offers, pointing out that the power company would accept the law, spend its own money for the completion of the dam and be bound to serve the public without discrimination and for only a fair return.

Mr. Frothingham emphasized the desirability of utilizing the Muscle Shoals power for public utility so that it might fit in its logical place in superpower development. The Alabama Power Co., with its experience and good record as a public utility as well as by its prior interest in the development, should receive first consideration.

E. A. Yates, of the Wood, Hulse & Yates Co., engineer, went into the details of the power situation in the South. He argued for the distribution of the Muscle Shoals power as against concentrating the consumption there. Mr. Yates estimates the available power at Muscle Shoals at 2,100,000 kw.-hr. annually at 80 per cent efficiency and 100 per cent load factor. The absolute prime power, based on the average river flow for 22 years, is only 400,000,000 kw.-hr. yearly. As far as power is concerned, he concluded, the greatest benefit will be derived by distribution. The greater the system to which the dam is connected the greater will be the utilization of secondary power.

Little Interest in Dye Inquiry—End of Testimony in Sight

Completely overshadowed by the completion of the tariff schedule, the dye investigation dragged half-heartedly through another week without new developments. It is expected that hearings will be concluded within the next few days.

C. J. Thatcher, vice-president of the Thatcher Process Co. of Syracuse, N. Y., advanced the conclusion that industry can be developed to meet the needs of the country only by the selective embargo system. This conclusion is unescapable after a study of the tariff history and statistics of the United States for the past 40 years, he said.

The "concrete result of previous attempts to build up an American industry by ad valorem tariff protection was to give the German dye monopoly control of the American market," the witness declared.

Ward Thoron, treasurer of the Merrimac Manufacturing Co., of Lowell, Mass., and Huntsville, Ala., attacked the present system of licensing imports and asserted that it caused annoying and intolerable delays to the dye users. Mr. Thoron argued that a tariff would give the American dye and organic industry all the protection it needs; the selective embargo system would place dye users at a disadvantage in competing with foreign manufacturers on certain textile products, he declared, because of the delay entailed in obtaining necessary foreign dyes.

Connecticut Valley Engineering Societies Hold Annual Joint Meeting

Over three hundred members of the chemical engineering societies represented in the Connecticut Valley met at Hotel Bond in Hartford April 11 for the annual joint meeting.

The principal speaker was Dexter S. Kimball of the Engineering School of Cornell University and president of the American Society of Mechanical Engineers. The subject of his address was "Engineering Civilization." Dr. Kimball said that the only distinction between our civilization and the civilizations that preceded it consisted in a greatly increased production made possible by engineering methods. In no other respects do we differ from the nations of antiquity. Dr. Kimball believes that the science of engineering will provide a solution for the problems which have overwhelmed the nations in the past.

The second speaker on the program was Hiram Percy Maxim, who gave a very interesting talk on thee "Development of the Wireless Telephone." He sketched briefly the various contributions made by the men who have been the leading figures in wireless communication. Prof. Bristol gave an exhibit of his sound reproducer which has just been developed at his laboratories. Numerous tests showed the exact reproduction of both voice and musical instruments.

Chicago Chemists Club Elects Officers

Annual meeting and election of officers of the Chicago Chemists Club occurred at the quarters, 315 Plymouth Court, on the evening of April 7. The retiring president, Otto Eisenschiml, gave an exceptionally well received talk on the things for which the club stands. His kindly and genial good-fellowship is ever a source of warmth to the members, and the chief regret was that he could not remain the permanent president. The retiring secretary, Paul Van Clief, made an excellent speech. His faithful service over two régimes brought a vote of thanks from the membership.

The principal feature of the evening was an illustrated talk on crystalline forms of water by ex-President William Hoskins. Snow flakes are his hobbies and he wove a fairy tale in the telling, to the delight of the old and young alike.

Officers elected for the coming year were: Chester H. Jones, president; G. A. Menge, first vice-president; Otto Stanger, second vice-president; A. E. Schaar, secretary; Oscar H. Wurster, treasurer; William Hoskins and L. M. Tolman, trustees.

Government Kelp Plant to Be Enlarged and Operated as Private Enterprise

The kelp potash plant of the Bureau of Soils, U. S. Department of Agriculture, at Summerland, Cal., was sold and transferred on April 1 to Rodney Benson of Santa Barbara. This plant was constructed in 1917 and operated for 4 years as an experimental and demonstrational plant with a view to the development of processes for extracting potash and byproducts from the giant kelps of the Pacific. It was closed through Congressional action in 1921. The plant will be enlarged and put back into operation at once for the manufacture of "Kelpchar," a decolorizing carbon of very high activity, potash salts, and iodine. Dr. J. W. Turrentine, who was in charge of the plant throughout the period of the experimentation, after turning over to the government's successors the manufacturing data established there, will return to Washington, D. C.

Historic Powder Plant to Be Scrapped

E. I. du Pont de Nemours & Co., Wilmington, Del., have permanently closed their historic powder mills at Brandywine, near Wilmington, and the plant will be dismantled. The mills were founded 120 years ago, in 1802, by Eleuthere I. du Pont, and have been used continuously for the manufacture of powder and explosives up to a recent date. The plant site has been transferred to a realty company and the property will be disposed of to private interests, representing heirs of the original owners. The Brandywine mill was the first of its kind in this country and furnished munitions for the War of 1812 and the Civil War.

Exhibit of Industrial and Technical Photography to Be Included in Chemical Exposition

At a meeting held in the Waldorf-Astoria, New York, April 10, plans were discussed for the organization of an exhibit of commercial and technical photography. John H. Graff, of the Brown Co., acted as temporary chairman and presented a summary of the circumstances which seem to warrant an exhibition of this nature.

"During the last few years," said Mr. Graff, "photography has more and more developed to be an important factor in industry, commerce and science, and a number of large concerns have established permanent photographic departments of their own, as an aid to better efficiency in administration, engineering, research, buying, selling, advertising, education, co-operation and for many special purposes peculiar to the individual needs of the concerns."

Industrial photography can be divided roughly into three classes—work done with the ordinary camera, photomicrographic work and work requiring specially constructed equipment. The first class includes photographic records of accidents and control boards, photographs demonstrating evidence of waste and salvage, safety ideas and construction reports. The second class includes metallography, studies of concrete, powder, gelatin, bacteria, tanning, paint making and pulp and paper. In the special equipment class may be mentioned the "slow-motion" motion picture studies of physical tests and movements, aërial photography for topographic work and commercial photostat work.

Besides the valuable knowledge gained by such a conference and exhibition in regard to application, technique, equipment and material, it would demonstrate if it would be beneficial to form a permanent association for the development of industrial and technical photography and the necessary qualifications for the men selected to do this work. Such a convention would not only be of value to those who have already entered this field, or those who by an exhibition of this kind would be made familiar with the practicability of adopting it for their own use, but also to the manufacturers of photographic equipment and material and optical and other scientific instruments related to the same.

Among those attending the meeting were representatives of the U. S. Testing Co., Cooper-Hewitt Co., Ansco Co., Eastman Co., U. S. Rubber Co., Sharp & Hamilton, U. S. Bureau of Standards and Bausch & Lomb. It was agreed that the idea behind the movement is commendable and it was decided to arrange to hold the exhibit in connection with the Chemical Exposition in New York next September. Charles Roth, manager of the National Exposition of Chemical Industries, was elected chairman of a committee to consider further means of securing co-operation of the industries.

A second meeting will be held at the Chemists' Club, New York, on May 10, at which time it is hoped that those industries interested in the undertaking will have accredited representatives present.

South Urges Acceptance of Ford Shoals Offer

In consideration of the various lease offers for the Muscle Shoals, Ala., nitrate plants, the Senate Agricultural Committee last week heard Senator Underwood of Alabama and Colonel W. J. Borden of the Corps of Engineers, U. S. A. Senator Underwood urged acceptance of the Ford proposal. Colonel Borden said it would take 6 years to complete the nitrate project.

The Senate Committee on Appropriations in reporting the agricultural appropriation bill to the Senate adds $5,000 for investigations concerning the application of chemistry to agriculture.

Government to Sell Saltpeter

The War Department has called for bids for 40,000 tons of sodium nitrate. Opportunity will be offered for purchases of the material in quantities as small as 100 tons.

Government Exhibit on Dust Prevention Methods Planned at Fire Protection Convention

Numerous serious dust explosions and fires in the United States and Canada have led engineers in the Bureau of Chemistry of the United States Department of Agriculture to arrange an exhibit showing the need for preventive measures and the results of work that has been done. The exhibit, which will be shown first at the annual convention of the National Fire Protection Association at Atlantic City, May 8 to 12, will include three phases of dust explosion and fire prevention.

One panel of the booth will be devoted to the problem in its relation to industries where grain is milled or handled or where food products are made. It will include such plants as grain elevators, sugar refineries, flour mills, starch factories, and cocoa and spice mills. Another panel will show the danger of dust explosions in threshing machines and methods of prevention. This danger is always present where threshing is being done, but is more to be feared during dry weather and when there is much smut in the grain. The third danger emphasized in the exhibit is that of cotton gin fires. In this case there is technically no dust explosion, but the fine fibers of cotton, once a fire has started, burn with almost explosive violence. Such fires are often started by electric sparks generated by the rubbing of the cotton on metal pipes through which it is passing. Drawings and photographs will be displayed showing methods for reducing the danger.

Accompanying this three-panel booth will be a stereomotorgraph which will be used to show views of industrial plants, threshing machines and gins that have been wrecked or damaged by explosions or fires. The entire exhibit will be available for the use of associations or similar organizations interested in the prevention of dust explosions or fires. Application should be made to the United States Department of Agriculture.

Uncertainty as to Freight Rates Holds Up Raw Materials Orders

Decided differences of opinion exist among the members of the Interstate Commerce Commission in the matter of the proposed reduction in rates. Rumor has it that certain members believe that the railroads can afford no reductions at this time. Some believe rates can be reduced on basic commodities, while others believe there should be a general reduction on all commodities. With such a situation existing, it is obvious that a considerable delay may ensue. So far as coal is concerned, the psychological moment was passed when the decision did not come down on April 1. Had it not been for the strike, the delay in handing down this opinion would have had a very serious effect on the coal industry. The delay is discouraging buying of many commodities.

It may be that the Interstate Commerce Commission will await the action of the Railroad Labor Board, since the decision in regard to wages has such an important bearing on rates.

Very few contracts for coal are being made at this time, but in most of those that are being made the buyer is insisting on a clause which provides that he is to have the benefit of any reduction which may be made in freight rates.

New Government Bulletin on Edible Corn Oil

The result of its investigations into the preparation of an edible oil from crude corn oil has just been published by the United States Department of Agriculture as Department Bulletin 1010, a professional paper. A detailed account of the various processes in use is given, together with a discussion of experiments on the refining of corn oil under various modifications of the usual methods. A comparison is made of the economics of the methods proposed, and detailed plans of a commercial refining plant are presented. The bulletin is entitled "The Preparation of an Edible Oil From Crude Corn Oil." Copies may be obtained of the United States Department of Agriculture, Washington, D. C.

Proposed Working Clause in Patent Laws Modified as Result of Protests

Such sentiment against compulsory working of patents was evidenced at the initial hearing on that subject that Senator Stanley determined to redraft his bill. He expects to eliminate the 5- and 2-year limitations and change his bill so as to prescribe that patents shall be worked within a reasonable time, to be determined by the Commissioner of Patents.

Thomas E. Robertson, the Commissioner of Patents, declared his unalterable opposition to a working clause, because he believes it is imperative that the patentee have a monopoly. It is necessary, he said, to encourage invention and also is necessary to make the patent readily salable. A working clause, he declared, would discriminate greatly against the small inventor. He pointed out that the term of patents was changed from 14 to 17 years because it was shown that profits accrued mainly in the latter part of the term.

It was pointed out at the hearing that a large number of patents are taken out for protective purposes only during the research period. For that reason it was held that compulsory production would have the effect of giving a body blow to all research.

Frederick P. Fish, widely known patent attorney of Boston, and A. C. Oliphant, of the Federated American Engineering Societies, were among those who appeared against the bill.

The position of the Secretary of War and of the Ordnance Department was that the national defense is involved in the matter of patents, particularly when foreigners are not required to manufacture in this country.

Up-to-Date Powdered Coal Installation for T. C., I. & R.R. Co. Power Plant

The Tennessee Coal, Iron & Railroad Co., after thoroughly investigating the economies made possible by the use of pulverized coal as a fuel for steam generation, has decided to use it for its new boiler installation at Ensley, Ala. A contract has just been closed with the Fuller Engineering Co., Allentown, Pa., for the installation of the complete coal-driving, pulverizing and conveying systems to serve this plant and for burners and feeders for five 834-hp. Stirling boilers designed to operate at 200 per cent of rating.

The boilers will be situated approximately 600 ft. from the pulverizing plant and the fuel will be conveyed directly to the boiler bins by means of the Fuller-Kinyon transport system. The fuel will be diverted from the main line to the individual service bins through distributing valves and branch lines. The bins will be equipped with automatic bin recorders, which will keep the operator advised at all times as to the fuel conditions in the service bins.

New Sulphur Mining Plant for Freeport Co.

The Freeport Sulphur Co., New York and Freeport, Tex., awarded contract on March 24 to Dwight P. Robinson & Co. for the design and construction of a complete sulphur-mining plant at Hoskins Mound, Tex. Cloyd M. Chapman has been retained by the Freeport Sulphur Co. as consulting engineer.

The company now operates a large sulphur-mining plant at Freeport, Tex., consisting of four units which were built in the period from 1913 to 1918 by Westinghouse, Church, Kerr & Co., which has since been merged into Dwight P. Robinson & Co. This plant contains one of the largest installations of oil-burning boilers in the world.

Canadian Rolling Mill Destroyed by Fire

The east wing of the plant of the Vancouver Rolling Mills at Richmond, B. C., was destroyed by fire on the evening of March 31, with an estimated loss of between $50,000 and $60,000, about half of which is covered by insurance. Already plans are being made for the rebuilding of the plant.

Exposition of Power and Mechanical Engineering Planned for New York in December

Announcement has been made of the National Exposition of Power and Mechanical Engineering to be held at the Grand Central Palace, New York, from Dec. 7 to 13, 1922, by the managers of the exposition.

The exposition was decided upon by a group of engineers and manufacturers who had felt the need for such a means of having men get together, exchange ideas, see the latest development in equipment and lay problems before the manufacturer. It will be the foremost exposition of this kind and the first distinctly power exposition ever held. A number of progressive manufacturers have already engaged space for their exhibits.

The exposition will immediately follow the annual meeting of the American Society of Mechanical Engineers, and it is expected that the exhibits will supplement the programs and discussions at the professional meetings of the society. The professional divisions of the society will hold sessions relating to fuels, stokers, steam power plants, railroads, steam utilization in the paper industry, textile and gas power, and it is expected that the exhibits at the exposition will throw interesting light on the papers presented at these sessions of the A.S.M.E. meeting.

That the exposition will be comprehensive may be inferred from the plans, which are to include exhibits of every type of machine, apparatus, equipment, instrument, device and the various materials and supplies necessary in the operation of the complete power plant. The committee decided that its keynote should be "an exposition of apparatus employed in the generation, distribution and utilization of power."

The advisory committee for the exposition is under the chairmanship of I. E. Moultrop of the Edison Electric Illuminating Co. of Boston, and includes a number of prominent engineers.

Chemists of Thirteen Countries Meet to Promote International Good Will

An international meeting of chemists is to be held in Utrecht, Holland, June 21 and 23. Invitations have been sent to 100 chemists residing in thirteen different countries. These include men from the United States, Great Britain, France, Germany, Italy, Holland, Russia, Austria, Czechoslovakia, Denmark, Norway, Switzerland and Sweden. The purpose of the meeting is primarily scientific and social. A number of addresses will be presented by chemists in attendance at the meeting, but it is not the intention to undertake legislation with regard to chemical matters or other functions which are at present performed by the International Union of Pure and Applied Chemistry. The latter meeting is to be held at Lyons, France, June 28, and has not thus far included German or Austrian chemists.

Will Honor Pasteur on Centenary of Birth

The centenary of Pasteur's birth is to be celebrated at Strassburg next year and plans are under way for erecting a monument to his memory. Anyone desiring to make a contribution for the Pasteur centenary may do so through a committee which has been organized at Stanford University, consisting of Carl Alsberg, R. E. Swain and E. G. Martin. Prof. E. G. Martin, the chairman, may be addressed at the Department of Physiology, Stanford University, California.

Obituary

JOHN BALLOT, president of the Minerals Separation North American Corporation, died on Saturday, April 1.

KNOX TAYLOR, president of the Taylor-Wharton Iron & Steel Co., died on April 4 at his home at High Bridge, N. J. Mr. Taylor was the fifth generation of his family to manage the company, which was found in 1742. He was born at High Bridge, Oct. 19, 1873, son of the late William Johnston Taylor and of Mary Alward Taylor. He began his education at Chester, N. J., where for a time his father operated an iron blast furnace. Later he attended the Hill School at Pottstown, Pa., the Model School at Trenton, and was graduated from Princeton University with the degree of Bachelor of Science in 1895. In college he was a member of the track, athletic and football teams, and was selected as all-American guard. Mr. Taylor's love of outdoor life led him to engage in mining engineering work in the Rocky Mountains for 7 years after leaving college. He was a member of several clubs and associations, among them being the Engineers' Rocky Mountain and University clubs, American Society for Testing Materials, American Institute of Mining and Metallurgical Engineers, American Chemical Society, American Society of Mechanical Engineers, Society for Promotion of Engineering Education and Iron and Steel Institute (England).

Personal

A. E. BONN has resigned as general sales manager of the American Cyanamid Co. and as vice-president of the Air Nitrates Corporation and is now president of Bonn & Co., New York.

J. R. FRITZE has resigned as assistant metallurgist of the Keystone Steel & Wire Co., Peoria, Ill., to accept the position of chief metallurgist for the Avery Co. of the same city.

L. F. FROST, formerly with the Lisk Manufacturing Company, Ltd., Canandaigua, N. Y., the Enamel Products Co., Cleveland, and the Phillips-Clark Stone Co., Geneva, N. Y., has become chemist in charge of research and production with the Vitreous Enameling Co.

R. E. HALL has been appointed to take charge of the physical laboratory of the Pittsburgh station of the Bureau of Mines, where he will be engaged on solubility investigations. Mr. Hall was formerly with the Koppers Co., Pittsburgh, and with the Geophysical Laboratory, Washington.

J. K. HAYWOOD, chairman of the insecticide and fungicide board of the Bureau of Chemistry, completed 25 years' service with the bureau recently and was the recipient of a gold watch tendered him by his associates in the bureau and by former members of the Bureau of Chemistry staff.

G. A. HENDRIE, formerly assistant to the vice-president of the American Cyanamid Co., is now vice-president of Bonn & Co., New York.

ROBERT D. LANDRUM, chemical engineer for the Harshaw, Fuller & Goodwin Co., Cleveland, Ohio, has become vice-president in charge of development and sales for the Vitreous Enameling Co. and the Vitreous Steel Products Co., both of Cleveland.

M. LARUE has resigned his position as chief metallurgist of the Avery Co., Peoria, Ill., to accept a position with the Sherwin Williams Co. to do special sales promotion work in its St. Louis district.

JOHN MCCONNELL, formerly of the Interstate Iron & Steel Co., is now vice-president in charge of operation of the United Alloy Steel Corporation, Canton, Ohio.

J. W. REA, assistant engineer of the Eastern Clay Products Co., Pittsburgh, Pa., gave an interesting illustrated lecture on "The History and Manufacture of Vitrified Clay Pipe" before a meeting of the Allentown (Pa.) branch of the American Association of Engineers, on April 6.

HERBERT V. STEINER, New York, has been elected president of the Coplay Cement Manufacturing Co., Coplay, Pa., to succeed Ferdinand Loeb. GEORGE A. CHRIST, of Allentown, Pa., has been re-elected secretary and treasurer of the company.

BIRGER H. STROM is now research chemist in the Boston & Montana Department of the Anaconda Copper Mining Co., Great Falls, Mont.

DEAN E. WINCHESTER, for many years on geological work on coal, petroleum and oil shale for the U. S. Geological Survey and the Standard Oil Co. of N. J., has recently opened an office in Denver for geological practice, with special attention to petroleum and oil shale.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Statistics on Paper Production

A summary of production, shipments and stocks in the paper mills of the United States during the month of February, 1922, has recently been compiled by the Federal Trade Commission. From these statistics it will be observed that the total production for all grades of paper was 501,817 net tons in February, 1922, as compared with 407,966 tons in the corresponding month of the preceding year and 463,841 tons as the average for the years 1917-21 inclusive. Shipments during February, 1922, exceeded 490,000 tons, and in the same month of 1921 amounted to 383,679 tons.

Likewise stocks on hands at the different paper mills at the beginning and end of the month were slightly larger than on corresponding dates in the previous year.

The principal increases in production were in the case of paperboard and boxboard, wrapping and bag paper, fine writing and book paper, and felt and building paper. The output of standard and special grades of newsprint showed marked decreases both in quantity and number of mills in operation. Only 65 were in active production in February, 1922, as compared with 88 in the preceding year.

Under the caption "Loss of Production" the report points out that in February, 1922, 934 paper machines were idle, as compared with 1,065 in February, 1921. The total number of idle hours in the later month was 128,842 and in February, 1921, over 202,000. Of the total number of machines not in operation during the second month of the current year, 580 were idle because of lack of orders, 124 for repairs and 230 because of lack of material, power or for other reasons.

Comparing the stocks on hand at the domestic mills on Feb. 28 with their average daily production, based upon the combined production for 1918-21, the figures show that:

Newsprint paper mill stocks equal 6 days' average output.

Book paper mill stock equals 13 days' average output.

Paperboard mill stocks equal 10 days' average output.

Wrapping paper mill stocks equal about 25 days' average output.

Fine paper mill stocks equal about 34 days' average. output.

Total paper mill stocks of all grades equal about 14 days' average output.

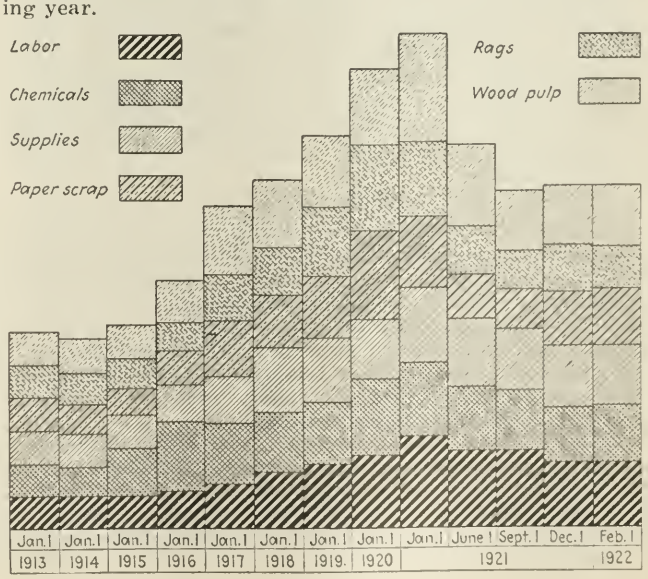
INDEX NUMBERS FOR FACTORS ENTERING INTO PAPER PRODUCTION COSTS

	1922	1921				1920	1919	1918	1917	1916	1915	1914	1913
	FEB. 1	DEC. 1	SEPT. 1	JUNE 1	JAN. 1	JAN. 1	JAN. 1	JAN. 1	JAN. 1	JAN. 1	JAN. 1	JAN. 1	JAN. 1
Wood Pulp	190	188	169	243	327	226	218	206	205	124	101	103	100
Rags	126	135	115	139	227	253	211	140	136	91	93	96	100
Paper Scrap	175	160	122	131	214	271	190	150	166	105	84	95	100
Supplies	183	185	190	210	225	181	178	178	138	118	105	102	100
Chemicals	173	170	181	196	220	223	191	179	188	216	143	90	100
All Mat'rials	171	171	157	202	271	230	207	180	175	122	103	99	100
Labor	204	204	234	234	276	225	197	168	130	111	100	100	100
Material & Labor	178	178	173	208	272	229	205	178	166	120	102	100	100

Paper Production Costs

An interesting study of the factors entering into the cost of producing paper is afforded by the accompanying table and chart prepared from data issued by the American Writing Paper Co., of Holyoke, Mass. The figures used are index numbers each based on a value of 100 for Jan. 1, 1913.

It will be noted that labor and wood pulp, which were the two most important elements in paper production costs in the peak month of January, 1921, still continue at comparatively high levels. Chemicals used in paper making were selling for 73 per cent above the 1913 figure on Feb. 1, 1922, having increased 3 per cent since Dec. 1 of the preceding year.



CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

This week	158.81
Last week	158.36
April, 1917	207
April, 1918 (high)	286
April, 1920	261
April, 1921 (low)	140

This index number is based on the wholesale prices in the New York market for acetic acid, citric acid, hydrochloric acid, nitric acid, sulphuric acid, ethyl alcohol, methanol, anhydrous ammonia, ammonium sulphate, barium chloride, bleaching powder, borax, caustic potash, caustic soda, copper sulphate, formaldehyde, glycerine, potassium carbonate, saltcake, soda ash, crude sulphur, benzene, aniline oil, cottonseed oil and linseed oil.

The New York Market

NEW YORK, April 16, 1922.

The chemical market during the past week showed signs of irregularity in some directions, while in others a moderate volume of new orders gave an encouraging light to the general situation. The advancing tendency of the foreign exchange market was fully reflected in prices for shipment of chemicals from abroad. European inquiries for solid caustic soda continued to reach the market and prices are holding very firm. Soda ash is holding its own without any important feature. Prussiate of soda still remains in an easy state under an absence of any buying interest. Copper sulphate is moving moderately for export and domestic consumption. Glaubers salt and cyanide of soda dealers are finding extreme difficulty in selling goods even at material price concessions. Domestic producers of cyanide still quote the market at 26c. per lb. Chlorate of soda is finding a better outlet and the market seemed more active during the latter part of the week. Nitrate of soda is decidedly firmer and sulphate of ammonia is still lacking in the spot market, with shipment goods held at a premium for limited quantities. Higher prices for citric acid in Italy and the proposed tariff of 18c. per lb. have created a firmer market here, although the present domestic market is not very active. With the active season directly ahead, dealers are looking forward to a very strong condition in the citrate market.

General Chemicals

Acetic Anhydride—Producers report moderate trading on the basis of 38c. per lb., with a possibility of some shading on round lot business. The general quotation ranges from 38@40c. per lb., according to quantity.

Carbon Bisulphide—Sales were recorded at 6c. per lb. by first hands, f.o.b. works. Spot prices range from 6¼@7c. per lb., depending on the seller and quantity. The movement is rather quiet at present.

Cyanide of Soda—Domestic material is being sold in a regular way to consuming quarters, but importers are finding great difficulty in moving supplies. Imported material ranges from 22@24c. per lb., depending on the strength.

Caustic Soda—Inquiry for export remains quite active and several fair-sized orders were reported at $3.60@$3.65 per lb. f.a.s. Producers can offer only June-July shipment at $3.60. Leading jobbers offer small lots at $3.80@$3.90 per 100 lb. Producers offer contracts at 2½c. per lb., basis 60 per cent, f.o.b. works.

Calcium Chloride—Manufacturers report a steady market for the ground and solid grades. Carload lots of solid are offered at $24 per ton New York, and $21 per ton f.o.b. works. Granular is held at 1½c. per lb. New York and $27 per ton f.o.b. works. The demand from the roads and refrigerating industry is fully up to expectations.

Carbon Tetrachloride—Leading dealers offer car lots at 9½c. per lb. Smaller quantities command a premium up to 12c. per lb. The market is reported steady.

Sal Ammoniac—Imported, white is quoted at 7@7½c. per lb., depending on the quantity. The gray is higher at 7½c. per lb. with offerings rather scarce. The domestic is held at 7½@8c. per lb. The general outlook seems rather bright for this chemical.

Vegetable Oils

Linseed Oil—The market at the end of last week was very strong and prices named by leading domestic crushers ranged from 81@83c. per gal. Several crushers advanced quotations to 83c. per gal. and it was thought that all sellers would soon come up to this level, provided the seed market holds. There was a much better demand for nearby oil, and with foreign oil much higher, the general tone of the market was very firm. Imported oil was advanced to 76c. per gal., April shipment, duty paid, New York.

Chinawood Oil—Buyers' offers were a shade under those of the sellers during the week and actual business was not up to expectations, considering the active inquiry. Spot oil was offered at 13¾c. per lb., in less than carload lots.

Coconut Oil—A good inquiry was noted for this material for shipment over the latter part of the year and several carlot orders have already been recorded for this shipment. Domestic Ceylon type oil for Aug.-Sept.-Oct. shipment went through at 7¼c. per lb. The New York market was quoted at 7⅜c. per lb., sellers' tanks, immediate shipment.

Corn Oil—The latest figures on actual sales were recorded around 9¾c. per lb., sellers' tanks, f.o.b. Chicago, indicating an easier market. The demand for refined oil was quiet and prices around 12½c. per lb. were heard.

Peanut Oil—Offerings of crude domestic oil were heard at 10c. per lb., tank cars, f.o.b. mills, Southeast. Oriental crude, in bond, was quoted at 8½@8¾c. per lb. Pacific coast. Local dealers of refined oil were asking 12½@12¾c. per lb., carlots. The demand was moderate.

Annual Reports

Celluloid Co. Shows Deficit.—The report of the Celluloid Co. for the year ended Dec. 31, 1921, shows a deficit of $1,146,239 after depreciation, inventory reduction, taxes and other charges. This is to be compared with a net income of $1,072,413 for 1920. The total income prior to deductions was $36,752, as against $2,055,532 for the previous year. Depreciation of $300,000, an inventory reduction of $428,352 and other charges amounting to $454,639 were deducted from the 1921 income.

American Smelting & Refining Co. Shows Smaller Income.—The net operating income from this company's smelting and refining plants before providing for bond interest, depreciation, obsolescence, ore depletion, etc., was $8,180,970.13, a decrease of $5,108,649.44 as compared to 1920. After making all deductions the net income from the year was $1,591,908.92 in comparison with $6,674,778.70 in 1920.

"The main factors in the year's poor showing," says the report, "was the extremely small production of copper, zinc and tin." The company's output of its principal products in 1920 and 1921 are compared with the pre-war year 1914 in the following table:

	1921	1920	1914
Gold (oz.)	1,780,205	1,849,048	2,540,911
Silver (oz.)	75,354,443	77,732,911	77,604,483
Platinum and palladium (oz.)	863	936	1,664
Lead (tons)	207,612	205,249	316,591
Copper (lb.)	348,888,000	590,850,000	529,686,000
Spelter (lb.)	14,628,614	44,106,253	15,748,000
Nickel (lb.)	120,080	375,167	356,187
Tin (lb.)	11,915,954	18,511,160	.....
Sulphuric acid (lb.)	9,952,000	51,688,000	24,296,000
Arsenic (lb.)	5,155,522	17,695,266	6,184,000
Copper sulphate (lb.)	2,237,471	3,618,172	6,798,000
Byproduct metals (lb.)	3,232,488	1,549,426	1,678,228
Sulphur dioxide (lb.)	154,794	8,154,734	.....

The report also includes the following operating statistics, which are of interest in connection with the decreased earnings and lower volume of production:

	1921	1920	1914
Number of men employed	7,605	13,330	12,179
Total wages and salaries	$11,440,480	$20,164,508	$10,212,591
Average wage per 8-hr. day	$4.17	$5.04	$2.33
Tons charge smelted	2,583,142	4,050,751	4,171,258
Tons bullion refined	357,062	505,535	588,718
Tons coal used	302,924	499,713	544,619
Tons coke used	263,384	394,014	447,761
Barrels fuel oil used	1,432,085	1,294,299	976,528
Cubic feet gas used	837,012,321	2,674,177,277	7,430,300
Tons ore mined	2,205,537	2,311,946	1,266,702
Tons coal mined	360,952	509,424	257,942
Tons coke produced	100,860	181,664	129,650

National Leather Co. Has Small Profit.—The annual report of this company and its subsidiaries for the year 1921 shows total sales amounting to over $23,500,000 and a surplus from earnings of nearly $200,000. Inventories had been reduced to the extent of about $1,000,000.

President George H. Swift, in his letter to stockholders, stated that considerable improvement had been noted during the last months, although the volume of sales had not expanded to the extent expected last October.

"It is apparent that at the present time," according to Mr. Swift, "the biggest problem facing the tanning business is the lack of satisfactory demand from the users of leather. It is exceptional to find a buyer who will anticipate his requirements more than a short time ahead. In other words, practically all buyers are buying in a hand-to-mouth manner, which, however, is a natural sequence after a period of declining prices such as we have gone through in the past two years."

The St. Louis Market

ST. LOUIS, April 14, 1922.

An active market in this locality may still be reported, although there was a temporary lull of a few days shortly after the beginning of the month. A complete recovery has been made, however, and at the present time the volume of business transacted is as good as—in fact, better than—any previous month. There are no important price changes to report at this time, and in general prices are firming up considerably.

ALKALIS

The alkali market has declined somewhat, although *caustic* and *soda ash* maintain a normal basis both in price and demand. *Bicarbonate of soda* has declined quite a bit of late and can now be obtained as much as 35c. per 100 lb. cheaper than 2 weeks ago. Whether this price is as yet reflected in the consumer's purchase remains to be seen but the jobbers have already taken advantage of it.

GENERAL AND SPECIAL CHEMICALS

The heavy *mineral acid* market remains the same, with a good demand and firm prices. *Citric acid* is now coming to life, with a very good demand, and this should continue with the approach of the summer season. There has been no change in the *white arsenic* situation. *Bromides* continue to be in good demand. A brisk demand for *carbon bisulphide* has been reported, with no change in price. The demand for *carbon tetrachloride* is routine. *Copperas* demand is still beyond production, with prices remaining the same; however, one manufacturer has temporarily withdrawn from the market. The previously anticipated slump in *glycerine* has finally made its appearance, and the price has accordingly declined 1c. per lb. Drums are now selling for 15c. per lb. *Sulphur* is holding firm at the same price level of 2 weeks ago, and with an increasing demand. An advance in price might be expected in the near future. The demand for *zinc sulphate technical* is routine, and prices prevailing 2 weeks ago are still in force; however, an advance may be expected at any time.

VEGETABLE OILS AND NAVAL STORES

Castor oil is holding its own with ease, though some spot goods can be had at less than the market price. The *linseed oil* market is showing the effects of heavy importations and American producers are at quite a disadvantage. Our prices have slightly recuperated from the low price of 84c. reached a few days ago and are now being maintained at 86c. Whether the home producers can control the market further is doubtful, and consumers are generally holding back for lower prices. *Turpentine* fluctuates daily, but the variation in price has been rather limited since reaching the low figure of 85c. last week.

PAINT MATERIALS

Paint manufacturers are experiencing a very serious slump just now that has decreased their anticipated demands greatly. *Barytes, lithopone* and *zinc* are not moving as would ordinarily be expected at this season, but manage to maintain their price level of a month ago.

The Iron and Steel Market

PITTSBURGH, April 14, 1922.

An unexpected development has occurred in connection with the coal strike inaugurated April 1, as a part of the Connellsville region and by far the major part of the Lower Connellsville region have gone on strike. A few strikes had been expected in the coke region, chiefly or wholly at works that have lately been paying less than the Frick or Steel Corporation wage scale, but there have been many strikes at Frick plants also. The United Mine Workers claim that most of the men are "organized," but the organization is no doubt of more or less makeshift character. On account of the disposition of Connellsville region workers to celebrate the Easter holidays very extensively the operators have taken no steps toward resumption, but next week strenuous efforts will probably be made to operate. Meanwhile the Frick company has moved many willing workmen from the Lower Connellsville to the Connellsville or old basin, putting idle ovens in operation.

No coal or coke, of course, had been stored in the Connellsville region, and little coke was stored at the blast furnaces tributary to Connellsville ovens, the result being that half a dozen or more blast furnaces have been banked or blown out, while orders pending to blow in about the same number have been suspended. The Connellsville and Lower Connellsville regions had been supplying coke for 20 or 25 per cent of the total blast-furnace operations of the country, and the coal shipments were also of some importance to the iron and steel industry.

The results of the Connellsville development must be distinguished from results that would follow exhaustion of the large stocks of coal that exist in the country. It is conceivable, though improbable, that the Connellsville labor troubles might last long enough to produce such a decrease in pig iron and steel production that finishing mills, now well stocked with coal, might be unable to use all the coal, on account of shortage of steel.

The effect of the Connellsville labor troubles upon the iron and steel market has been to cause merchant blast furnaces in several districts to withdraw prices entirely or to make advances of, say, $1 a ton. An extreme case is that of basic pig iron at valley furnaces, which a week ago was quotable at $18 furnace, but has just sold at $20 for 1,000 tons of standard grade and at $19 for 4,000 tons of off grade.

With pig iron stiffening and with coal supplies for the future more or less menaced, steel works have been disposed to become reserved in selling steel products. The Jones & Laughlin Steel Co., whose coal mines are union, has withdrawn entirely from the steel market, as it already had large steel commitments, with a moderate stock of coal. All the independent wire mills have advanced nails, staples and barb wire $2 a ton, making nails $2.50 a keg, but the Steel Corporation wire subsidiary has not followed up to this time. The recently advanced prices in sheets are reported to be fully effective, 2.40c. for blue annealed, 3.15c. for black, 4.15c. for galvanized and 4.50c. for automobile sheets, but as buyers had ample opportunity to cover at the old prices the market is now very quiet. Bars, shapes and plates remain quotable at 1.50c. as the general market.

SELLERS' ATTITUDE STIFFENED

The coal strike, with the ramifications developed, is a new factor, operating to curtail iron and steel production somewhat and to stiffen the attitude of sellers. Steel production had been mounting rapidly. There is an interesting question whether steel production would have continued to increase after April 1 if there had been no coal strike, also a question whether there would have been nearly as much increase in production to April 1 if no coal strike had been on the program. Estimating the rate of steel ingot production month by month on the basis of the monthly reports of the production of thirty producers, and plotting the average rates in the months December to March inclusive, the graph is almost a straight line. The rate in December was about 19,750,000 tons per annum and the rate in March about 32,500,000 tons. Continuing the line to April 1, as seems justified by the news in March, the rate on that date was about 36,000,000 tons. Obviously no such climb could continue for even a few months. Common observation is sufficient to show that actual consumption of steel has not so greatly increased. Presumably consumers in general have fortified themselves against a curtailment of supplies due to the coal strike which the coal strike may not produce even though in its first fortnight it has been more formidable than coal and furnace interests expected.

Limited quantities of Westmoreland County, Pan Handle and Connellsville coal have been in the market in the past week, but asking prices have been mounting and buyers have largely lost interest. Connellsville furnace coke has become unquotable. Occasional odd lots have been offered at fancy prices, while the average furnace will not pay over $3.50 for a supply, preferring to bank. Foundry coke has been available at $4.75@$5 25, against $4.25@$4.75 ruling as the market for several weeks, during which time most foundries were stocking.

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.30 — .31
Aniline oil, drums extra	lb.	.16 — .16½
Aniline salts	lb.	.24 — .26
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.25 — 1.30
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb.	.75 — .85
Benzoic acid, U.S.P.	lb.	.60 — .65
Benzoate of soda, U.S.P.	lb.	.55 — .57
Benzene, pure, water-white, in drums (100 gal.)	gal.	.29 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.27 — .32
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech.	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.60 — .65
Beta-naphthol, tech	lb.	.26 — .28
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97–99%, straw color, in drums	gal.	.53 — .55
Cresylic acid, 95-97%, dark, in drums	gal.	.48 — .50
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.95 — 1.00
Dimethylaniline	lb.	.38 — .40
Dinitrobenzene	lb.	.23 — 25
Dinitroclorbenzene	lb.	.23 — .25
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.33 — .35
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Diphenylamine	lb.	.59 — .65
H-acid	lb.	.85 — 1.00
Meta-phenylenediamine	lb.	.90 — 1.00
Monochlorbenzene	lb.	.14 — .15
Monoethylaniline	lb.	1.20 — 1.25
Naphthalene crushed, in bbls.	lb.	.06 — .06½
Naphthalene, flake	lb.	.06¾ — .07
Naphthalene, balls	lb.	.08 — .08½
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17½
Ortho-amidophenol	lb.	2.75 — 2.80
Ortho-dichlor-benzene	lb.	.15 — .20
Ortho-nitro-phenol	lb.	.75 — .80
Ortho-nitro-toluene	lb.	.12 — .15
Ortho-toluidine	lb.	.16 — .20
Para-amidophenol, base	lb.	1.25 — 1.30
Para-amidophenol, HCl	lb.	1.30 — 1.35
Para-dichlorbenzene	lb.	.15 — 18
Paranitroaniline	lb.	.75 — .77
Para-nitrotoluene	lb.	.70 — .75
Para-phenylenediamine	lb.	1.50 — 1.55
Para-toluidine	lb.	1.10 — 1.15
Phthalic anhydride	lb.	.35 — .38

Phenol, U. S. P., drums	lb.	.12 —	15
Pyridine	gal.	1.75 —	2.75
Resorcinol, technical	lb.	1.30 —	1.35
Resorcinol, pure	lb.	1.75 —	1.80
Salicylic acid, tech., in bbls	lb.	.24 —	.24½
Salicylic acid, U. S. P.	lb.	.25 —	.26
Solvent naphtha, water-white, in drums, 100 gal	gal.	.25 —	.28
Solvent naphtha, crude, heavy, in drums, 100 gal	gal.	.10 —	.12
Sulphanilic acid, crude	lb.	.25 —	.27
Tolidine	lb.	1.20 —	1.30
Toluidine, mixed	lb.	.30 —	.35
Toluene, in tank cars	gal.	.25 —	28
Toluene, in drums	gal.	.30 —	.35

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—The Dixie Chemical Products Co., is planning for the erection of a new addition to its plant. D. H. Markstein is president.

TUSCALOOSA—J. H. Thress has construction nearing completion on a new brick-manufacturing plant and will install equipment and start operation at an early date. The site is on the outskirts of the city. The plant will cost about $22,000.

EUFAULA—The City Council is planning for the installation of a new filtration plant and system at the waterworks.

Arkansas

EL DORADO—The El Dorado Oil & Pipe Line Co. is planning for the rebuilding of the portion of its oil plant, recently destroyed by fire.

California

RICHMOND—The Luning Mineral Products Co., 21st St. and Chanslor Ave., manufacturer of mineral pigments used for paint production, has plans under way for the construction of an addition to its plant to more than double the present output.

Colorado

DENVER—The Continental Rubber Corp., recently organized under state laws, has negotiations in progress for the purchase of a local site to be used for the construction of a new plant for the manufacture of automobile tires and other rubber goods. A. E. Sidnell is president and treasurer.

Connecticut

VERSAILLES—The Inland Paper Board Co., Inc. recently organized, has taken over the local plant of the Federal Paper Board Co., comprising a number of buildings and over 600 acres of land, and in the future will operate at this location for the manufacture of composition paper-board specialties. A number of improvements will be made in the mill, including the erection of a 1-story power house. The new company is headed by William G. Shortess and Frank Mousley.

Delaware

YORKLYN—The National Fibre & Insulation Co. is arranging for the discontinuance of the plant of the American Vulcanized Fibre Co., at Newark, Del., recently acquired, devoted to paper manufacture and kindred production, and will combine the mill with its main plant at Yorklyn.

Florida

ORLANDO—The Orlando Pottery, operated by the Yowell-Drew Co., is having plans drawn for the erection of an addition, to include a new kiln. The equipment installation is estimated to cost close to $13,000. Bids will be asked early in May. Gamble & Bryan, East Liverpool, O., are engineers. N. P. Yowell is president.

HOMESTEAD—Fire, April 2, destroyed a portion of the local building of the Independent Fertilizer Co., with loss estimated at about $13,000.

Georgia

COLUMBUS—The Bradley Fertilizer Co., 8th St. and Tenth Ave., is reported to be planning for the immediate rebuilding of the portion of its plant destroyed by fire, March 24, with loss estimated at $90,000, including equipment.

Illinois

CHICAGO—The Byproducts & Coke Corp., 112th St. and Torrance Ave., has commenced the construction of a new 1-story coke-oven plant, 20 x 550 ft. Charles Stewart, 53 West Jackson Blvd., is engineer.

Indiana

MISHAWAKA—The Rubber Regeneration Co. is planning for the rebuilding of the section of its plant destroyed by fire, March 28. The loss has not been announced.

Iowa

DAVENPORT—The recent reference to the fire loss sustained at the plant of the Mammoth Glucose Co., March 30, reported at $300,000, occurred at the works Nichols Wire & Sheet Co., occupying a portion of the glucose plant under lease, and in a section owned by Charles Brady, who purchased the entire plant from the Corn Products Refining Co., the previous owner.

Kentucky

RUSSELL — The Kentucky Refractories Corp., Covington, Ky., has acquired property at Russell, totaling about 15 acres of land, and plans for the erection of a branch plant for the manufacture of firebrick, furnace linings and other refractory products. The works will be equipped for an output of about 75,000 bricks and other refractory units daily, giving employment to approximately 175 men. The cost is estimated at about $350,000, including machinery. A. J. Ivey is secretary and treasurer.

Louisiana

HOMER—The local refinery and oil plant of the Homer Oil & Refining Co. has been acquired by H. C. Leete and A. C. Lea, both of Shreveport, La., who will organize a company and operate the plant. The refinery will be remodeled and improved.

HOUMA—The City Council is planning for the construction of a new purification plant at the municipal waterworks. A bond issue of $200,000 has been voted for this and other municipal improvements.

Michigan

GRAND RAPIDS—The Valley City Milling Co., 217 Michigan St., has completed plans and will soon call for bids for the erection of a new flour mill to cost about $600,000, including equipment. The A. E. Baxter Engineering Co., Ellicott Square, Buffalo, N. Y., is engineer. William S. Rowe is president.

MONROE—Fire, April 2, destroyed the plant of the Weis Fibre Container Co., with loss estimated at about $1,000,000. The plant has been giving employment to about 300 men. It is planned to rebuild at an early date.

Missouri

ANNAPOLIS—The Annapolis Lead Co. will soon break ground for the erection of a new concentrating plant, to be equipped for a daily production of about 1,000 tons. A power house will also be constructed. The work is estimated to cost in excess of $400,000. M. C. Rhodes is president.

PHENIX—The Phenix Marble Co. is pushing construction on its new local plant and plans for early occupancy. It will be equipped for the manufacture of lime products, whiting and kindred specialties, and is estimated to cost $60,000.

JEFFERSON CITY—The Strawboard Mfg. Co. has preliminary plans under way for the erection of an addition to its plant.

New Jersey

PASSAIC—The Paterson Parchment Paper Co., 35 8th St., has awarded a contract to William Hassan, 625 Main St., for the erection of a 2-story addition, to cost about $50,000. The Solomon-Abbott Co., 175 5th Ave., New York, N. Y., is engineer.

EAST RUTHERFORD—Fire, April 10, destroyed two buildings at the plant of the Flintkote Co., Madison and Central Aves., manufacturer of asphalt shingles, waterproofing products, etc., with loss estimated at close to $100,000. Headquarters of the company are at 88 Pearl St., Boston, Mass.

KEYPORT—The County Gas Co., formerly the Standard Gas Co., is planning for extensions and improvements in its local water gas plant, to cost about $150,000. William J. Clothier is vice-president.

New York

FREEVILLE—The United Fertilizer & Lime Co., Merchants' Bank Bldg., Syracuse, N. Y., will build a new 1-story fertilizer manufacturing plant at Freeville, 45 x 75 ft.

OAKFIELD—The United States Gypsum Co., 1170 Broadway, New York, will build a new addition to its plant at Oakfield, used for the manufacture of panel boards and other gypsum products.

Pennsylvania

PHILADELPHIA—The Belmont Packing & Rubber Co., Butler and Sepviva Sts., manufacturer of mechanical rubber products, will break ground at once for the erection of a 2-story addition, 35 x 75 ft. The building contract has been let to George W. Crossley, 2264 Bridge St.

HAZLETON—The Thomas Leather Co. has been organized to take over and operate the plant of William Olewine, 9 East Broad St. Possession will be taken at once, and a number of improvements are contemplated. The new company is headed by Herbert F. and T. Frank Thomas.

South Carolina

CHARLESTON—The Consolidated Gas Co. is planning for extensions and improvements in its plant to cost about $40,000. A new purifier department to cost $25,000 will be installed.

Tennessee

KNOXVILLE—The Kinney Chemical Co., 727 Broadway, is planning for the erection of a 2-story plant, 25 x 150 ft. About 6,500 sq.ft. will be given over to chemical manufacture. F. L. Kinney is head.

Texas

DALLAS—John J. Simmons has awarded a contract to Lawrence Miller, Dallas, for the erection of a 3-story and basement plant for the manufacture of chemicals and chemical byproducts, estimated to cost about $50,000. Barglebaugh & Whitman, Dallas, are architects.

DALLAS—The Trinity Paper Mills Co., 3010 Williams St., is arranging a list of equipment for installation at its plant to provide for a capacity of about 4 tons of waxed and other papers per day. The machinery will include waxing equipment, slitters, winders, etc. J. Y. Webb is president, and R. G. Smythe, manager.

FREEPORT—The Freeport Sulphur Co. has commissioned Dwight P. Robinson & Co., engineers and contractors, 125 East 46th St., New York, N. Y., to prepare plans for its proposed new plant at Hoskins Mound, near Brazaria, Tex., on property recently leased from the Texas Co. It will cost approximately $500,000, with machinery.

CAMERON—The Cameron Water, Power & Light Co. is planning for the installation of a new water treatment and purification plant at its local waterworks, estimated to cost about $40,000.

HOUSTON—The Model Brick Co., recently organized, has plans under way for the erection of a new plant for the manufacture of brick and other burned clay products, and will take bids for the buildings and equipment during May. The initial output will approximate 12,000 bricks per day. W. J. Carter and J. F. Meyer, both of Houston, head the company.

THREE RIVERS—The Three Rivers Glass Co., 520 Bedell Bldg., San Antonio, Tex., recently organized, is having plans prepared for the erection of its proposed new plant at Three Rivers, consisting of a main building, 50 x 150 ft., and auxiliary structures. The company will specialize in the manufacture of bottles, and will develop an output of about 100 gross per day. Automatic glass-blowing machinery and other equipment will be installed. James Kepp is president, and H. L. Warrick, general manager.

West Virginia

WHEELING—The City Council has called a special election on April 24, to vote bonds for $2,000,000 for water-works extensions and improvements, including a new filtration plant. The Board of Water Commissioners is in charge.

Wisconsin

PARK FALLS—The Flambeau Paper Co. is perfecting plans for the rebuilding of its 2-story pulp and paper mill, estimated to cost about $100,000. Work will be commenced at an early date. Thomas W. Orbison, 812 College Ave., Appleton, Wis., is engineer. Guy Waldo is general manager.

New Companies

THE FLORIDA GLASS & NOVELTY WORKS, INC., Jacksonville, Fla., has been incorporated with a capital of $20,000, to manufacture glass specialties. C. E. Harris is president; Charles A. Powers, vice-president; and Harry W. Herwig, secretary and treasurer, all of Jacksonville.

THE K-B MFG. CO., Trenton, N. J., has been incorporated with a capital of $125,000, to manufacture alkalis and kindred products. The incorporators are Abraham S. Lewis and Harry Chalt. The company is represented by Alexander Budson, 901 American Mechanic Bank Bldg., Trenton.

THE AMERICAN BRICK CO., INC., Berlin, Conn., has been incorporated with a capital of $75,000, to manufacture brick and other burned clay products. The incorporators are E. M., M. F. and George A. Pickett, all of Berlin.

BARCAN & ZIEGLER, INC., New York, N. Y., has been incorporated with a capital of $50,000, to manufacture chemicals, chemical byproducts, dyes, etc. The incorporators are E. D. Ziegler, M. Reiber and I. Barcan. The company is represented by Louis Levy, 277 Broadway, New York.

THE HARLEM RUBBER CO., 1652 North Kostner Ave., Chicago, Ill., has been incorporated with a capital of $10,000, to manufacture rubber products. The incorporators are George C. Siebert and Joseph A. Netzel.

THE VERTOXEL PRODUCTS CO., Newark, N. J., has been incorporated with a capital of 500 shares of stock, no par value, to manufacture bleaching powders and kindred products. The incorporators are Walter Marvin, 13 Margaretta St., Newark; Henry I. Tanner and Otto Eckert.

THE ORIENTAL LABORATORIES, INC., Memphis, Tenn., has been incorporated with a capital of $5,000, to manufacture chemicals and chemical byproducts. The incorporators are C. L. Gibbes, W. H. Steadman and W. H. Daniel, all of Memphis.

THE VELLEY CHEMICAL CO., Wilmington, Del., has been incorporated under state laws with capital of $3,000,000, to manufacture chemicals and chemical byproducts. The company is represented by the Corporation Service Co., Wilmington.

THE APUL TOWNSEND LABORATORIES, INC., New York, N. Y., has been incorporated with a capital of $275,000, to manufacture lubricants and affiliated products. The incorporators are W. E. Townsend, A. J. Paluszek and E. H. Paul. The company is represented by R. J. Mullen, 192 State St., Brooklyn, N. Y.

THE CONSUMERS' SERVICE CO., Pittsburgh, Pa., is being organized by W. J. Woolums, C. C. Bowker and L. W. Bowker, to manufacture refined petroleum products. Application for a state charter will be made on April 24. The company is represented by W. G. Heiner, 602 Frick Bldg., Pittsburgh.

THE MAGNESITE PRODUCTS CO., 31st and Cicero Sts., Chicago, Ill., has been incorporated with a capital of $50,000, to manufacture magnesite, lime, cement, etc. The incorporators are A. J. Petit, Frederick W. Snider and Edmund S. Cummings.

THE WONDER MINERAL & CHEMICAL CO., 3127 Park Blvd., Detroit, Mich., has been chartered under state laws to manufacture chemicals, chemical byproducts, etc. The incorporators are Warren W. Alger, James F. Williams and John Blenk.

THE DAMASCUS REFINING & MFG. CO., New York, N. Y., has been incorporated under Delaware laws with capital of $5,000,000, to manufacture refined petroleum products. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

THE ELWOOD BRASS & ALUMINUM MFG. CO., Elwood, Ind., has been incorporated with a capital of $20,000, to manufacture brass, bronze and aluminum products. The incorporators are C. P. Rush, Henry Nauman, R. T. Boston and O. D. Hinshaw, all of Elwood.

THE FARMERS' & GINNERS' OIL MILL, INC., Austin, Tex., has been incorporated with a capital of $200,000, to manufacture cotton oil products. The incorporators are Leigh Ellis, H. Wunderlich and G. C. Quinn, all of Austin.

THE BRADLEY OIL CO., Wilmington, Del., has been incorporated under state laws with a capital of $4,000,000, to manufacture refined petroleum products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE TEXTILE CHEMICAL CO., INC., Providence, R. I., has been incorporated with a capital of $50,000, to manufacture chemicals, dyes and kindred products. The incorporators are Frank S. Shapiro, Mark Weisberg and Philip W. Lown, 5 Mt. Vernon St., Providence.

THE GRIFFITH-CUSTER STEEL CO., Johnstown, Pa., has been incorporated with a capital of $60,000, to manufacture steel products. Benjamin F. Custer, Johnstown, is treasurer.

THE ELDORADO DEVELOPMENT CO., Eldorado Springs, Mo., has been incorporated with a capital of $300,000, to construct and operate a lead and zinc mill and smelter. A. B. Stricklett is president, and L. T. Dunaway, secretary, both of Eldorado Springs.

THE QUALITOL LABORATORIES, INC., Buffalo, N. Y., has been incorporated with a capital of $100,000, to manufacture chemicals and affiliated products. The incorporators are O. C. McFarland and M. E. Buie. The company is represented by Coatsworth & Diebold, 438 Main St., Buffalo.

THE A. W. LEE OIL CO., Oklahoma City, Okla., has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are A. W. and R. G. Lee, both of Oklahoma City.

THE FOURLOCK TILE CORP., Tuckahoe, N. Y., has been incorporated with a capital of $10,000, to manufacture tile and other burned clay products. The incorporators are J. Goldberg and C. F. Bailey. The company is represented by A. S. Mortimer, 111 Broadway, New York.

THE ACME COLOR CO., Boston, Mass., has filed notice of organization to manufacture chemicals, colors, etc. The company is headed by William W. Schofield, 97 High St., Boston.

THE OHIO VALLEY ROCK ASPHALT CO., Summit, Ky., has been incorporated with a capital of $500,000, to operate an asphalt mining and refining plant. The incorporators are R. G. Price, Joseph S. Laurent and Dover Williams, Fountain City, Tenn.

THE J. C. O'CONNOR CO., INC., Pittsburgh, Pa., has been incorporated with a capital of $100,000, to manufacture sheet steel products. H. E. Askin, 1825 Webster Ave., Pittsburgh, is treasurer.

THE GULF PHOSPHATE CORP., Dover, Del., has been incorporated under state laws with capital of $18,750,000, to operate a phosphate mining plant, manufacture fertilizer products, etc. The company is represented by the United States Corporation Co., 65 Cedar St., New York, N. Y.

THE LOTZ ASBESTOS CO., Hartford, Conn., has been incorporated with a capital of $100,000, to manufacture asbestos products. The incorporators are A. V. Nyquist, C. A. Jordan, Jr., and John Lotz, Jr., 94 Beacon St., Hartford.

THE DIXIE CO., Fairmont, W. Va., has been incorporated with a capital of $10,000, to manufacture lubricating oils. C. H. Neill is president; G. G. Smith, vice-president; and J. D. Alexander, secretary, all of Fairmont.

THE VENEZUELAN PETROLEUM CO., Pearl River, N. Y., has been incorporated under Delaware laws with capital of $5,000,000, to manufacture petroleum products. The company is represented by the Registrar & Transfer Co., 900 Market St., Wilmington, Del.

THE MCGREGOR OIL & MFG. CO., McGregor, Tex., has been incorporated with a capital of $50,000, to manufacture oil products. The incorporators are H. E. Hackney, J. D. Naler and C. P. Shaffer, all of McGregor.

THE HOOSIER PAPER CO., Marion, Ind., has been incorporated with a capital of $25,000, to manufacture paper products. The incorporators are P. W. Slevin, Andrew Scheerer and C. C. Nelson, all of Marion.

THE JEWELL OIL CO., Lexington, Ky., has been incorporated under Delaware laws with capital of $100,000, to manufacture petroleum products. The incorporators are John B. and M. H. W. Jewell, and Harry M. Rowe, Lexington. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington, Del.

THE CRANE CHEMICAL CO., Brooklyn, N. Y., has been incorporated with a capital of $100,000, to manufacture chemicals and chemical byproducts. The incoprorators are J. W. Crane and J. E. Glen. The company is represented by G. L. Robinson, 31 Nassau St., New York.

THE COLUMBIANA FOUNDRY CO., McKeesport, Pa., has been incorporated with a capital of $5,000, to manufacture iron, steel and other metal castings. F. B. McConnell, McKeesport, is treasurer.

THE KENLATEX OIL CO., Wilmington, Del., has been incorporated under state laws with capital of $500,000, to manufacture petroleum products. The company is represented by the Delaware Charter Co., 904 Market St., Wilmington.

THE UNITED STATES PRODUCTS CORP., Wilmington, Del., has been incorporated with a capital of $125,000, to manufacture chemicals and chemical byproducts. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington.

Capital Increases, Etc.

THE PENNSYLVANIA POTASH ACID FERTILIZER CO., Westfield, Pa., has filed notice of increase in capital from $350,000 to $1,000,000.

THE GEORGIA FULLERS EARTH CO., 26 Cortlandt St., New York, N. Y., has filed notice of increase in capital from $400,000 to $1,000,000.

THE WHITAKER-GLESSNER CO., Wheeling, W. Va., manufacturer of steel products, has disposed of a bond issue of $4,500,000, the proceeds to be used for general financing, operations and expansion.

THE GENERAL PETROLEUM PRODUCTS CO., 94th and Tinicum Sts., Philadelphia, Pa., has filed notice of increase in capital from $150,000 to $750,000.

THE RECTOR CHEMICAL CO., INC., 2 Rector St., New York, N. Y., has filed notice of dissolution under state laws.

THE LA BELLE IRON WORKS, Steubenville, O., manufacturer of steel slabs, billets, sheets, etc., has disposed of a bond issue of $4,000,000, the proceeds to be used for general financing and operations.

THE MOODY OIL & REFINING CO., Wichita Falls, Tex., has filed notice of increase in capital from $5,000,000 to $21,500,000.

THE POCOT OIL CO., Tonawanda, N. Y., has filed notice of increase in capital from $10,000 to $100,000.

Industrial Developments

PAPER—The Hinde & Dauch Paper Co., Sandusky, O., has resumed operations at its mill at Muncie, Ind., which has been closed for about a year past. The working force will be increased as rapidly as the plant can be placed in condition for operation.

Practically all of the paper mills in the New England district are increasing operations and adding to the working forces.

The Spanish River Pulp & Paper Mills, Ltd., Montreal, Que., is advancing its working schedule and is now operating at close to capacity.

The International Paper Co., New York, N. Y., has commenced the manufacture of paper at its new mill at Three Rivers, Que., which previously has been operating in part for the production of sulphite pulp. The plant has a rated capacity of 96 tons of paper daily, and it is expected to develop this maximum in the near future.

All of the paper mills at Escanaba, Mich., have resumed operations both in the pulp and paper divisions, following an idleness of a number of months. About 400 men have been added to the working forces.

RUBBER—The Firestone Tire & Rubber Co., Akron, O., has advanced its production schedule to a basis of 20,000 tires a day, as compared with an output of 17,000 tires daily in recent weeks.

The Seiberling Tire & Rubber Co., with plants at Barberton, O., and New Castle, Pa., has increased operations to a point of 1,600 tires and 2,000 tubes per day. Additional workers will be employed in the near future.

GLASS—The Pittsburgh Plate Glass Co., Pittsburgh, Pa., has increased production at its different plants to approximately 90 per cent of normal capacity.

The Ball Bros. Glass Mfg. Co., Muncie, Ind., is giving employment to about 1,500 operatives at its plant, and plans for increased operations, with additional workers, at an early date.

CERAMIC—The Enduro Porcelain Enameling Co. Middletown, Pa., a subsidiary of the Wincroft Stove Works, is maintaining full capacity operations at its plant, and has adopted a day and night working schedule.

The National Fireproofing Co., Perth Amboy, N. J., is increasing production at its local plant and adding to the working force. The present schedule is close to capacity output, with 10-hour working day.

METALS—The Anaconda Copper Mining Co., Butte, Mont., is increasing production at its local plants, with employment of an increased working force. The Washoe smelter at Anaconda, Mont., and the Great Falls, Mont., plants are in active operation.

The Utah-Apex Mining Co., Bingham, Utah, has resumed operations at its local properties, following a suspension for more than a year past. Employment will be given to about 250 men, with output of about 450 tons of lead ore per day.

Practically all of the metal-refining plants at Perth Amboy, N. J., have increased the April production schedule, as compared with the February and March outputs, and a large number of additional men are be-

ing employed. The different plants include the American Smelting & Renning Co., the United Lead Co. and the Raritan Copper Works.

A number of copper compaines in the vicinity of Ray, Ariz., have resumed operations at their properties, following a shutdown for about a year past. The principal companies, under one management, include the Utah Copper Co., the Ray Consolidated Copper Co., and Chino Copper Co. and the Nevada Copper Co. The present basis of production will be increased gradually.

The Calumet & Hecla Copper Co., Calumet, Mich., has resumed operations at its plant. Other copper companies in this same section are re-opening, including the Isle Royale Copper Co., and the Ahmeek Copper Co., giving employment to a total of about 2,000 men.

IRON AND STEEL—The Monongahela Tube Co., Clairton, Pa., is arranging for the immediate operation of its No. 2 furnace on day and night shifts, giving employment to about 175 men. The plant has been idle since late last year.

The Canton Sheet Steel Co., Canton, O., has resumed operations at its plant, effective April 17, following a shut-down for some time past.

The Tennessee Coal, Iron & Railroad Co., Birmingham, Ala., is operating its Ensley steel works at full capacity, and broke all previous production records during March, with the ingot mill manufacturing 96,000 tons, and the blooming mill 75,000 tons. One of the blast furnaces at the plant is being repaired and will be placed in service at an early date.

The Otis Steel Co., Cleveland, O., has opened its new sheet mill, and will soon bring the plant up to capacity. Present production is on a 75 per cent basis.

The Republic Iron & Steel Co., Youngstown, O., has blown in another blast furnace at its Hazleton plant, making the third unit in operation.

The Central Steel Co., Massillon, O., is increasing production at its mills, and six of the nine furnaces are now in operation. Further increase will be made at an early date.

The Sharon Steel Hoop Co., Sharon, Pa., is making ready to blow in its blast furnace at Lowellville, Ohio.

Manufacturers' Catalogs

THE L. R. CHRISTIE Co., Pittsburgh, Pa., has recently issued a new catalog showing various types of driers and containing two interesting articles by L. R. Christie, one on "Dryer Engineering" and the other on "Dryer Efficiency," which are illustrated by curves of some value to the engineer.

CHARLES ENGELHARD, INC., New York, is issuing Bull. A-23 on "Impervite Hard Porcelain and Impervite Refractory Porcelain."

THE SHEPARD ART METAL Co., Detroit, Mich., announces the publication of a booklet on "Shepard Die Castings." In it there is a chapter about die castings, illustrations and description of closed body hardware, polished nickel finish; die castings in zinc base alloys; die castings in aluminum; die castings in tin base metals, and die castings in lead alloys.

THE GRISCOM-RUSSELL Co., New York, in Bull. 360 describes "Griscom-Russell Evaporator Systems for the Economical Production of Distilled Boiler Feed Water." The application of evaporators to the purification of boiler feed water by distillation is covered in a general and non-technical way. The booklet is written so that the application of Reilly evaporators can readily be understood by the non-technical executive as well as the engineer.

THE ESTERLINE-ANGUS Co., Indianapolis, Ind., in Bull. 322 illustrates and describes various types of its graphic meter.

THE ATLAS VALVE Co., Newark, N. J., has issued a booklet on "Reducing Valves," giving tables and rules for determining the capacity of reducing valves and pipe connections; also for determining the capacity and flow of steam in pipes of different diameters and different losses in pressure. Copies will be sent upon request.

THE UEHLING INSTRUMENT Co., Paterson, N. J., calls attention to Bull. 112, covering Uehling CO_2 recording equipment for guiding the engineer and fireman in reducing the waste of fuel up the chimney. Particular attention is called to the recently developed "Pyro-porus" filter, shown on page 10, an exclusive Uehling feature, which is claimed to be very efficient in keeping the gas sampling lines clean. Other noteworthy features are the separate recorder for the engineer's office and indicator for the boiler front continuous (not intermittent) chart record and dry method of absorption.

W. S. ROCKWELL Co., 50 Church St., New York, has issued Bulletin 240, on "The Heat-Treatment of Springs With Stationary and Continuous Furnaces." This is one of a series of well-written pamphlets outlining the many factors controlling the methods of applying and utilizing heat and handling material in the modern metallurgical plant.

MERCK & Co., New York, are distributing a new edition of their booklet "Blue Label Reagents and Other Laboratory Chemicals." Copies will be sent to anyone interested on request.

THE DENVER FIRE CLAY Co., Denver, Col., has published an attractive bulletin on Oil Burners. This company is endeavoring to carry out an educational campaign in all its bulletins, making them useful for something besides the selling of its products, and in this bulletin the first twenty-one pages are devoted exclusively to the general discussion on various methods of using oil as fuel, while the last twelve pages are devoted to illustrations and descriptions of low-pressure burners, high-pressure burners, the combination burner, the high-low burner, the motorblower, blast valve, tuyere, refractories and illustrations for furnaces using DFC burners.

THE COMBUSTION ENGINEERING CORP., Broad St., New York, calls attention to a folder on Type K automatic stoker for small plants, and a booklet on the application of pulverized coal to locomotives. This latter booklet entitled "Lopulco Pulverized Fuel System for Locomotives," tells of the interesting phases of this company's pioneer work and contains a number of informative test reports.

WALLACE & TIERNAN Co., INC., of Newark, N. J., has just issued a new technical publication, No. 30, describing its bacteriological testing outfit and other chemical testing outfits useful in the control of water purification.

THE PYROLECTRIC INSTRUMENT Co., Trenton N. J., announces the publication of Catalog 19. It contains this company's complete line, including apparatus for low-resistance measurements, electro-dynamometer, electrometers, furnaces, galvanometers, hydrogen-ion apparatus and chemicals, inductances, keys and switches, laboratory accessories, meters for d.c. measurements, pyrometers and thermocouples, pyrovolter type instruments, resistances and resistance thermometers. Illustrations are given.

THE HOYT METAL Co., St. Louis, Mo., has issued a booklet on Products of Rolling Mill and Pipe Departments.

THE NATIONAL CARBON Co., INC., New York City, has just issued "The Carbon Electrode," an 80-page booklet containing many scientific and engineering data relating to the manufacture and use of electrodes in electric furnaces. The booklet contains also some useful hints on the handling, joining and storage of electrodes, as well as some useful electrode "don'ts."

THE SURFACE COMBUSTION Co., New York, N. Y., has ready for distribution Bulletin 3D on Surface Combustion Low-Pressure Air-Gas Inspirators. These inspirators are designed so as to be readily applicable to any make of gas furnace.

THE STANDARD CALORIMETER Co., East Moline, Ill., calls attention to Booklet 102, on "Directions for Using the Parr Sulphur Bombs and the Parr Sulphur Photometer."

SCHUTTE & KOERTING, Philadelphia, Pa., has just issued a new bulletin on "Air Jet Lift Equipment." This booklet is well illustrated, showing the action of the air jet lift, also several applications. Formulas and tables are given showing capacities under various conditions of air pressure handling different liquids.

THE HARDINGE Co., New York, N. Y., calls attention to a new bulletin on Quigley Fuel Systems, comprising methods of preparing, transporting and burning of pulverized fuels. This bulletin is known as No. 12 and treats the subject of pulverized fuels. Emphasis is laid upon the methods employed properly to prepare and burn the powdered coal, rather than occupying most of the space discussing the pulverizer. Aside from complete plant layouts, what it terms as a "Unit Milling Plant" is described. The system comprises a method of pulverizing and transporting the coal to one or more furnaces in the same locality, at the same time obtaining positive regulation and continuous operation over extended periods. A partial list of users is given.

THE PHILADELPHIA COPPERSMITHING Co., Philadelphia, Pa., has issued Catalog "S," descriptive of its sugar equipment. It announces that its research laboratories are in charge of Dr. Henry Arnstein and that it is equipped to handle problems dealing with chemicals (organic or inorganic), dyes, pharmaceuticals, food and food substitutes, sugar, motor fuel from vegetable and residual sources, vegetable oil, soap, glycerine, etc., plants.

THE CENTURY WOOD PRESERVING Co., Pittsburgh, Pa., in Bulletin 20 describes the storing and seasoning of cross-ties.

Coming Meetings and Events

AMERICAN ASSOCIATION OF ENGINEERS will hold its eighth annual convention at Salt Lake City, Utah, June 4-6.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Baltimore, April 27, 28 and 29, 1922. Headquarters will be at the Emerson Hotel.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Rochester, N. Y., during the week of June 5, 1922. Meetings will be held in the spring instead of in the fall as heretofore

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its summer meeting at Niagara Falls, Canada, June 19 to 22. Headquarters will be at the Clifton Hotel.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its nineteenth annual meeting at Bigwin Inn, Bigwin Island, in the Lake of Bays district, Ontario, Canada, on June 21, 22 and 23.

AMERICAN OIL CHEMISTS' SOCIETY will hold its annual meeting at the Grunewald Hotel, New Orleans, La., May 8 and 9.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS will hold its spring meeting at Atlanta, Ga., May 8-11.

AMERICAN SOCIETY FOR STEEL TREATING will hold a sectional meeting at the Bureau of Mines auditorium, Pittsburgh, Pa., on May 25 and 26. The International Steel Exposition and Convention of the society will be held in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-fifth annual meeting June 26 to July 1, at Atlantic City, N. J. Headquarters will be at the Chalfonte-Haddon Hall Hotel.

AMERICAN WELDING SOCIETY will hold its annual meeting April 26-29 at the Engineering Societies Building, New York City.

ANNUAL SAFETY CONGRESS of the NATIONAL SAFETY COUNCIL will be held in Detroit, Mich., Aug. 28-Sept. 2.

CANADIAN INSTITUTE OF CHEMISTRY and the SOCIETY OF CHEMICAL INDUSTRY will hold their annual meetings in Ottawa May 15-17.

CERAMIC SOCIETY (London) is to have a foreign trip to Sweden and Denmark from May 27 to June 10.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY will hold a meeting at Lyons, France, June 27 to 30.

IRON AND STEEL INSTITUTE (British) will hold its annual meeting on May 4 and 5 at the House of the Institution of Civil Engineers, Great George St., S. W., 1, London.

NATIONAL ASSOCIATION OF PURCHASING AGENTS EXPOSITION (the "Informashow") will be held in connection with the seventh annual convention of the association at Exposition Park, Rochester, N. Y., May 15 to 22.

NATIONAL COAL ASSOCIATION will hold its annual meeting at Congress Hall, Chicago, May 24-25.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (EIGHTH) will be held in New York Sept. 11-16.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NATIONAL FERTILIZER ASSOCIATION will hold its twenty-ninth annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 12.

NEW JERSEY CHEMICAL SOCIETY will meet at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its national convention in Detroit, Mich., April 26-28.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists Club, New York: April 21—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting; May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting; June 9—American Chemical Society, regular meeting.

To Regulate Trade Associations

THE dilemma in which trade associations find themselves as the result of the Hardwood decision continues to be the subject of much discussion. The most recent developments include the Hoover conference at Washington and the introduction, in Congress, of a bill by Senator EDGE placing such associations under the Federal Trade Commission and of a joint resolution, fathered by Senator EDGE and Representative MCARTHUR, providing for a Congressional investigation.

"Business is entitled to know in definite terms what it may and may not do," declares the preamble of the proposed joint resolution. This declaration will strike a sympathetic chord in many a weary heart. For 50 years American business has been struggling to attain certainty of its legal status. Successively under the old common law doctrines, under the state anti-trust laws and under the federal Sherman act, business has been operating under the handicap of indefinite and negative restrictions. The process has been one in which business, denied definite positive guidance, has tentatively adopted in its tendency toward combination one legal form after another—the pool, the trust, the holding company, the merger—only to be checked and turned back by the Supreme Court, which has finally evolved that marvel of indefiniteness, the "rule of reason." The latest decisions have made it clear that combinations in restraint of trade cannot be erected under the guise of open-price associations. One more experiment tried and the check once more applied! Business now asks for a statement of what it can do.

The uncertainty which has been present has been costly in the past—much more costly than is ordinarily realized. If one were to attempt to devise a plan for dampening business enterprise, it would be difficult to evolve a more efficient implement than a threat of illegality.

It is not meant to infer that business should be left free to do anything it chooses. So long as competition is the force relied upon to protect consumers from high prices, it will be necessary to prevent by law combinations in restraint of trade. We merely point out that certainty as to what is legal and what is illegal would greatly simplify the problem of the business man. How can one proceed confidently so long as the rules of the game are undetermined and constantly shifting?

In this particular case, moreover, uncertainty is likely to be particularly costly. Unless positive guidance is given, the trade association movement will receive a blow which will prevent in large measure the performance of many functions which are highly useful in the economic process and quite free from objection on the grounds of restraint of trade. For the fact-finding function of the trade association is really a risk-elimination function. If a business man can make his plans and decisions on the basis of fact and knowledge rather than guess and speculation, he can price more closely, eliminating the reserves and insurance premiums which inevitably accompany the conduct of business when surrounded by uncertainties. Trade associations now supply many valuable data and can be so developed as to supply more. Such data are essential to wise business decisions and will result in fewer losses to business men and lower prices to consumers.

The Edge bill may not be perfect. Senator EDGE does not pretend that it is. But certainly his proposals are steps in the right direction. It is possible to define fairly precisely the things which trade associations "may and may not do" and Congress owes it to the business community and to the country to make this clear.

Completing the Picture of Industry

IN FRESHMAN CHEMISTRY DAYS we learned that sulphuric acid was the great barometer of industry—in fact, of civilization itself. At that time, to be sure, our ideas on this subject were quite hazy, but since then we have come to realize that literally hundreds of industries are dependent on this important chemical. Fundamental materials such as copper, steel sheets, gasolene and fertilizers cannot be produced in needed quantities without sulphuric acid. This product lies at the very foundation of all our chemical industries. But all these things are well known even to the average layman and would not be worth the repeating here were it not for their bearing on a problem which is now confronting our industries.

When Mr. HOOVER became Secretary of Commerce one of his first ambitions was to organize a statistical service which would give the business men of the country a ready and accurate picture of industry. Such a picture meant current figures on the production and consumption of all the basic commodities of commerce. In a large measure Mr. HOOVER'S plans have been successful. Manufacturers, consumers, trade associations and statistical bureaus have given fully of their information. But there has been one conspicuous and outstanding failure. The picture of industry has been complete except for one important element. Monthly figures are now published for iron and steel, coal, cotton and wool, corn and wheat, copper, petroleum—all these. But the great barometer of industry is lacking. The chemical industry, or rather one of its principal components, alone has refused to co-operate with the Commerce Department. We of the industry are entitled to know the reason for this refusal. We have been told that it is because the manufacturers fear that the consumers will use the information to the disadvantage of the producer. We suspect, however, that the reason

is this: The big fellow already has his own informational service and doesn't want to share it with the little fellow who can't afford such costly facilities.

There is another thing which any manufacturer who is refusing to give these figures should keep in mind. If enough of the other industries of the country insist that they have a real need for this information, the department is going to get it for them. A sympathetic Congress which has already shown its willingness to back up Mr. HOOVER'S work with increased appropriations will not hesitate to enact legislation that will compel the giving of this information.

The acid makers whose selfish motives have already done damage to the good name of the chemical industries may yet be made to realize their short-sightedness.

How Much Petroleum Shall We Need in 1930?

STATISTICIANS have often projected the curve of petroleum consumption during late years to estimate the needs of the future. But J. E. POGUE has recently pointed out the fallacy of using such a trend curve alone for estimating the future demands for crude petroleum. He shows that any really sound basis of estimate must take into account the changes in industrial practice and allow for the modification of refinery yields in accordance with the indicated tendency of recent years.

In 1920 we used 531 million barrels of crude petroleum in the United States. This figure had been reached by increases of 10 per cent per year in the consumption during the previous decade. If such rates of compounding of demand should follow for another 10 years, the 1930 requirement for crude petroleum would be 1,260 million barrels, quite properly characterized as "a staggering volume."

But during recent years there has been a decreasing rate of addition to the number of motor vehicles, for we are approaching somewhere near a point of saturation for this equipment. Moreover the yield of gasoline per barrel of crude oil has been greatly increased, particularly during the past 5 years. In 1916 the ratio of gasoline produced to crude oil consumed was 0.154. In 1918 the ratio had reached 0.206, and in 1919, 0.214. The 1920 figure showed a slight falling off, no doubt due to peculiar business conditions, but in 1921 the ratio was back again to 0.233.

On these assumptions POGUE projects the curve of crude petroleum requirements through the coming 10-year period and reaches very interesting conclusions. He demonstrates that the combined efforts of these factors is such that 585 million barrels of crude petroleum for 1925 and 580 million barrels for 1930 probably will be adequate to meet the demand for gasoline. These quantities are not much greater than the 1920 consumption. In other words, if the present tendencies of industry continue, we have already reached somewhere near the maximum demand for crude petroleum. The increased quantity of gasoline which is needed will be supplied, during the next few years at least, largely by increasing the yield of gasoline per barrel of crude refined. Thus improved technology will again help to meet and care for the changing economic conditions of the country.

Meanwhile, look out for benzene, alcohol, and the chap who some day soon will build up from lower hydrocarbons and end with "gasoline"!

The Shortest Distance Between Two Points

DID it never occur to you, especially when contemplating the layout and arrangement, or, better, lack of arrangement, in evidence in many manufacturing plants, that the meaning of the old axiom about a straight line had never really been accepted by most of us? Mankind seems to have a special fondness for devious ways and we never deviate more noticeably than in some of these same plants.

Should the inquiring mind attempt to ascertain the cause for this wavering path in industry, the reason most frequently given is that, in the hurry and stress of expansion, it has been impossible to arrange extensions of building and equipment in such a way that the process continues to flow in a straight line. This is undoubtedly true in a majority of cases; but there are also cases where the plant started off with a poor layout and has had it ever since.

Now the answer to this is: If you are stuck in the mud, take measures to get out. If the product of a plant is restricted and the cost of production is too high, if the workers are compelled to wait for materials and partly finished goods pile up in the open spaces and block the passages, if an undue proportion of the force is employed in just carting materials back and forth through the plant, then the owners of the plant, the managers and the technical staff should take immediate counsel among themselves to the end that these conditions may be relieved. The relief will undoubtedly lie in correcting the routing and may also, and in fact generally does, necessitate a change in the methods by which the materials are handled between various steps in the process.

One example of the results which can be obtained by merely straightening the flow of the goods through a plant has come to our notice recently and serves to show the results that follow correct routing alone, there having been no additional equipment utilized in this operation.

In this particular factory the manufacturing was all done in one building and the raw material used was light in weight. The process was rerouted so that the raw material—stored in the basement—was started in the course of manufacture on the top floor and one operation succeeded another until the finished goods were delivered at the shipping point on the ground floor without the line once crossing itself. The space and equipment were the same as had been utilized formerly, but the production increased about a fifth and the force of over 200 men was reduced by 20 who had formerly been employed in keeping the aisles clear and the machines supplied with material. A further advantage was that the inventory of goods in process was reduced to one-quarter of the amount formerly carried.

Another example: A pulp mill found it advantageous to relocate the chip house at a cost of over a hundred thousand dollars in order to make the flow of material straight enough to permit the use of conveyors through the plant and thereby cut down the man-handling of material to a minimum.

Many examples such as these could be cited; but they really form a small proportion of the industrial plants of the country and by far the greater number are still in a position to profit from an earnest contemplation of the straight line between the two points of receiving and shipping.

Aluminum for Engineering Structures

SEVERAL pages of a former issue were devoted to a digest of a very remarkable report by Messrs. ROSENHAIN, ARCHBUTT and HANSON on aluminum alloys —namely, the eleventh report to the Alloys Research Committee of the British Institution of Mechanical Engineers. In this issue a brief account of the most remarkable "Y" alloy is given.

Such excerpts give but an inkling of the material contained in the original report, which in turn is little more than a sketch of the results of 7 years' work by a staff numbering at times as high as thirty investigators, and commanding the unstinted resources of the British scientific laboratories. Truly, systematic researches into complex alloy systems have become most prodigious undertakings, far beyond the imagination of the sponsors of the program, started over 30 years ago. Yet it is well that the program was started so early. It is impossible to appraise the influence which the successive reports on steels, brasses, bronzes and aluminum alloys have had on modern technology—they are fundamental.

Aluminum alloys of high strength are not entirely new. The Germans have been using certain of them called "duralumin" for dirigibles since before the war. British and American firms have also been manufacturing duralumin for several years; shop practice is fairly well understood and many laboratory studies have been made on the somewhat bizarre occurrences during heat-treatment. Duralumin contains 3.75 per cent copper, 0.5 per cent magnesium, 0.65 per cent manganese. The present report extends our information by recording the development of "A" alloy, containing 3 per cent copper and 20 per cent zinc; "E" alloy, containing 2½ per cent copper, 20 per cent zinc and 0.5 per cent of both magnesium and manganese; and "Y," containing 4 per cent copper, 2 per cent nickel, 1.5 per cent magnesium.

These newer alloys have all been produced in quantity, and the peculiar combination of properties possessed by "Y" alloy should insure its extended use in industry. It is as light as aluminum, yet as strong as soft steel. It corrodes at an extremely low rate. It retains its strength at moderate temperatures, which fact, coupled with its high heat conductivity, should make it very valuable for engine cylinders and pistons. Furthermore, it has a high endurance limit; that is to say, "fatigue failures" after oft-repeated loadings do not occur until the impressed loads are well up toward the yield point. To appraise this particular property it should be remembered that it is more difficult to add 1,000 lb. to the endurance limit of a metal than it is to add 10,000 lb. to its tensile strength.

We need not expect light alloys of high strength to be adopted as quickly as the radio telephone. They are of course indispensable to aircraft, where weight is a very great consideration and dollars can be spent to save a single pound. Engineers and designers are only slowly realizing that weight is an important factor in all moving parts. But when they are able to convince manufacturers and owners that it is well to put more into a light car or engine and save on its subsequent operation, the aluminum alloys will still have to overcome the competition of heat-treated alloy steels, relatively cheap, very strong and reliable.

Although we can say with much assurance that light metals and alloy steels will form the large structures of the future, it would be vain speculation to attempt to define their mutual relation. The best that scientists can do is to show that such things as high-strength alloys exist; metallurgists then discover how to procure the raw materials cheaply (and here much remains to be done for aluminum) and produce the alloys economically and uniformly. Engineers must then show us how to use these new tools of civilization—even to developing an entirely new technique of design.

Variations in Steel Demand

MEN who are anxious to stabilize business so that things would keep going at a steady pace all the time might well turn their attention to the steel trade. Either they would accomplish something for the industry or they would learn some of the difficulties involved in attempting to modify the actions of others.

There was quite a lot of talk last year about regulating the coal industry because it had become so seasonal in character, more coal being mined in winter and less in summer. It would be better to maintain uniform production, accumulating stocks in summer and drawing upon stocks in winter. If that is a good idea, how about a trade which instead of carrying stocks for purposes of equalization does just the reverse, increasing or decreasing stocks in such manner as to make the swings all the more violent?

That trade is the steel trade. Since the middle of March production of steel has been between three and four times as great as in July, 1921. The producers are not responsible, for they have simply been producing steel as it was bought from them. They cannot run on stock to any extent.

In the first 8 or 9 months of 1920 there was a very insistent demand for steel. Then demand fell off and in July, 1921, the mills were producing steel ingots at only 11,000,000 tons a year when their capacity was between 50,000,000 and 55,000,000 tons. Then production, which was dictated solely by orders received, rose rapidly, and the rate on April 1 was fully 35,000,000 tons.

Last summer stocks of steel in the hands of buyers and manufacturers of steel, not previously distributed, were being drawn upon. In recent weeks, on the other hand, the country has been increasing its stocks again.

It may be said that in times of heavy demand stocks are requisite and in times of light demand they are not. If that were true, some good work could be done by altering the condition. One might suppose that the stocks that stood as a barrier to mill demand in the summer of 1921 had been but recently accumulated. Many steel companies, however, report the curious experience of having had claims made upon them in the past few months against alleged defectives, when the records showed the steel had left the mill in the early months of 1920, before the apparent "scarcity" of steel had reached its height.

Before attempts are made to establish uniform production in industries whose product is actually consumed at varying rates, by establishing stock piles, it would be well to inquire into the cases where variations in demand are produced by variations in the amount of stock carried. A general study would probably show that the variations in demand upon producers of primary material are caused more by psychological than physical reasons, that the ups and downs in market demand are produced more by what men think than by the amount of actual consumption.

Readers' Views and Comments

Atomic Disintegration of Tungsten

To the Editor of Chemical & Metallurgical Engineering

SIR:—I regret that a delay has been necessary since the publication of Dalton M. Goetschius' comment in your issue of April 12 on the recent experiments of Clarence E. Irion and myself in exploding tungsten wires with the production of helium, and regret too that Mr. Goetschius did not have a more complete account of the work on which to base his comment.

Mr. Goetschius is quite correct in pointing out the analogy between the process of explosion such as we employed and the collisions of dark stars in interstellar space. Prof. W. A. Noyes of the University of Illinois has already pointed out in private correspondence that this is "a possible explanation of the sudden flaring up of stars which is sometimes seen," and Dr. J. A. Anderson, in the original paper describing the method used (*Astrophysical Journal*, vol. 51, p. 37, January, 1920), calculated that the same wire which by this method is impressed with 30 calories of energy would generate no less than 80,000 calories in falling from outer space into the sun, though it would probably not reach nearly so high a temperature because of the much longer time required.

The criticism that the production of mercury from tungsten involves an increase in atomic weight and is therefore a startling result which deserves "third degree" examination is also wholly correct, but is based on misinformation. It is regrettable that this work has received so much newspaper publicity and general comment in advance of the publication of the complete paper. Our carefully nurtured chemical publicity is, for once, working all too well. Not only are details ambiguously stated even by the careful reporter for CHEMICAL & METALLURGICAL ENGINEERING but atomic transmutation has been presented to the general public as established when mere decomposition is all that we can hope to have accomplished, and even that is based on preliminary work which cries for confirmation by others, who, fortunately, are already at work.

A brief report on this work will appear soon in the *Proceedings* of the National Academy of Sciences and a complete account is being sent to the *Journal of the American Chemical Society*. From these it will be evident that the helium spectrum was the only one unmistakably present in the gases formed by the high-temperature explosion. There was a background which seemed to be the banded spectrum of nitrogen and there was always a faint evidence of the strongest green line of mercury. This last was mentioned as part of the record, but we cannot but suppose that it was due to a minute backward diffusion of mercury vapor from the pumps used to exhaust the system, escaping the liquid air trap and even the cold charcoal bulb also used for evacuation. It does not justify theoretical speculation. The gas produced in the explosion of a 0.0005 mg. wire occupied slightly more than 1 c.c., on the average, which if it is all helium corresponds to nearly half the entire material of the wire. This should set at rest doubts on the ground of adsorbed or included gases. A further point is that no hydrogen lines were ever observed, which is of interest because the atomic weight of tungsten, 184, is an exact multiple of the atomic weight of helium and in view of the fact that while Sir Ernest Rutherford was able to produce hydrogen in small quantities from B, N, F, Na, P and Al, whose atomic weights are not multiples of 4, he was not able to observe its formation from Li, Be, C, O, Mg, Si and S, which, except for the first two very small atoms, are multiples of the helium weight (*Phil. Mag.*, vol. 42, p. 809, 1921).

The Soldier Bonus and Editorial Independence

To the Editor of Chemical & Metallurgical Engineering

SIR:—On my way from Geneva to Basel I had the good fortune to meet Nobile Carlo Tommasi, administrator of the Lonza Co. of Basel. He is an engineer. When he learned that I am a member of your staff he took from his brief case the issue of CHEM. & MET. for March 1, 1922.

I glanced through the issue and read particularly the editorial on page 385 and the letters on page 390 relating to the soldier bonus. The next to the last paragraph of the letter signed by Messrs. Webster, Burrows and Wendel particularly attracted my attention on account of its reflection on members of your staff. I quote:

> Speaking as one "having experience, if not authority," you mention that five members of your staff are opposed to the bonus. After your first editorial, it is doubtful if they would come out openly in favor of the measure and still hope to retain their positions.

Of course the imputation is thoroughly unwarranted. May I inform the gentlemen that I am not one of the five members of your staff who are opposed to the bonus and yet I am still in your organization and hope to be a part of it as long as my work is satisfactory? I may add also that I am a former member of the Canadian Expeditionary Forces.

J. S. NEGRU.

En Route, Geneva to Basel,
March 14, 1922.

EDITOR'S NOTE: Although we closed discussion on the bonus, we decided to accede to Mr. Negru's request to comment on this phase of the discussion. He is now making a trip through Central Europe for this magazine.

Fundamental Research on Corrosion

To the Editor of Chemical & Metallurgical Engineering

SIR:—It is very necessary that only the purest metals, those prepared with the most extreme care, be used in studying the fundamental facts underlying the problem of corrosion.

I notice one of the sheets of metal used by the Corrosion Committee of the British Institute of Metals[1] was reported as 99.97 per cent pure. That three-hundredths of a per cent may be very vital in the production of whatever corrosion takes place. Particularly there comes to my mind as an illustration some pure zinc which we had for a determination of melting point

[1] See CHEM. & MET. ENG., Feb. 15, 1922, vol. 26, p. 301.

standards. There were two samples, both of which analyzed as excessively pure materials; one, however, dissolved in ordinary hydrochloric acid immediately and the other only after several days' standing. The only chemical difference that could be found in those two pieces was six-thousandths of one per cent of iron.

It seems to me that in carrying out any corrosion experiments to find the fundamental facts one must start with metals of the greatest purity, otherwise the results may be, if not wholly, at least very greatly misleading. GEORGE K. BURGESS.

Washington, D. C.

Causes of Corrosion in Brass

To the Editor of Chemical & Metallurgical Engineering

SIR:—One or two points brought out in the review of the findings of the Corrosion Committee, British Institute of Metals, published in your issue for Feb. 15, 1922, seem worthy of further comment.

I don't doubt for a moment that the accumulation of deposits in the inside of the condenser tubes is contributory to corrosion, but it does not explain the actual fact that out of a number of condenser tubes placed side by side in the same service, some fail in a few months and others last for years. Comparison of those tubes which have not failed with those companion tubes which do fail has not in my practice revealed any particular deposit on one tube that was absent in a companion tube. It seems as though there must be something more in it than merely the accumulation of deposits.

It does not seem to have been proved that dezincification does not actually occur, but is only apparent because the copper has built up out of the solution by plating back. Most condenser tubes are in service in which the circulating waters are going through very rapidly, and I think it would require considerably more proof than I have been able to find in this summary, that corrosion takes place not through dezincification but only by an apparent dezincification.

It seems to me that not enough attention has been paid to the crystal grain of the various brasses that have been used in the corrosion tests, or the condition of strain or anneal that may or may not be present, and which may be a contributing factor to the rapid deterioration of brass condenser tubes.

Washington, D. C. ALLERTON S. CUSHMAN.

Effect of Composition of Brass on Corrosion

To the Editor of Chemical & Metallurgical Engineering

SIR:—From a microscopic examination of a large number of corroded condenser tubes I have come to the conclusion that quite different action may be expected, according to whether the brass is high in copper and shows only the alpha constituent, or whether it is lower in copper and has a duplex microstructure.

Considering the latter, of which Muntz metal is typical, it was observed that the beta constituent is the first to become attacked, with the result that a porous reddish material, which is practically all copper, is left behind. It would appear that the zinc has been preferentially removed. In some cases the entire tube becomes brittle and almost non-metallic from this cause. Corroded Muntz metal does not generally show pitting, but loses its original metallic properties and breaks into pieces when hammered.

On the other hand, brasses containing more than 65 per cent copper and which have an entire alpha structure usually dissolve away and become thinner when corroded, but do not become brittle. All of the brass tubes are likely to pit, but as a rule the pits in an alpha brass tube are clean, whereas the pits in a Muntz metal tube are usually filled with porous cement copper. Pitting seems to favor the bottom inside portion of the tube, where solutions may concentrate and foreign matters lodge. Condensers at the present time are usually built so that the tubes lie in a horizontal position. If the design were changed so that the tubes would be placed in a vertical position, there would be less tendency for solutions to concentrate and remain in contact with the metal when the condenser is permitted to drain or when it is shut off and the water in the tubes gradually evaporates and leaves behind concentrated corrosive solutions of salts. PHILIP DAVIDSON.

Waterbury, Conn.

Electrolytic Concentration Cells as Accelerators of Corrosion

To the Editor of Chemical & Metallurgical Engineering

SIR:—Light may be thrown on the mechanism of corrosion of brass condenser tubes, discussed in your article[1] "Results Achieved by the Corrosion Committee of the British Institution of Metals," by some work done recently by R. J. Mackay of the International Nickel Co. at the Mellon Institute.

We are all familiar with what we call galvanic corrosion of metals—that is, the accelerated corrosion which results from the presence of two dissimilar metals or two dissimilar portions of the same metals in electrolytic contact. The more electro-positive metal corrodes and the other metal forms the cathode and absorbs the hydrogen which is given off. Mr. Mackay has demonstrated an analogous type of corrosion which he calls corrosion by electrolytic concentration cells, using an idea quite well known to electrochemists, but, as far as I know, not hitherto recognized in its relation to corrosion.

If a uniform rod of metal is placed in contact with a solution which has a different concentration of the corroding ion at one point than at another, that portion of the rod in contact with the more concentrated part of the solution will form the cathode and the other portion will form the anode and the metal will go into solution there. In this manner it is possible to develop differences of voltage between different portions of a perfectly uniform piece of metal, amounting to as high as 0.2 volt, and Mr. Mackay has demonstrated that this condition does cause accelerating corrosion.

The demonstration was made particularly in the case of copper alloys in $CuSO_4$:H_2SO_4 solutions, but he has also shown that it is true of cells which are made up of a concentration of oxygen or air at one portion of the metal and a deficiency of the air or oxygen at another. He has found that such a condition can accelerate the rate of corrosion by as much as fifty times over that when the solution and the metal are uniform.

Could not some of the cases of pitting that have been noticed in the corrosion of condenser tubes be due to somewhat the same situation—namely, that the solution concentrates with respect to the corroding ion lodged upon the surface of the tube and in consequence sets up a concentration cell by which accelerated corrosion results? PAUL D. MERICA.

Bayonne, N. J.

Thermal Problems of Petroleum Refining

Discussion of Petroleum-Refining Practice From the Combustion Engineer's Viewpoint—Adoption of Principles Proved in Other Process Industries Would Greatly Benefit Petroleum Industry—Secrecy and Use of Inbred Talent Is Destructive

BY L. A. MEKLER
Consulting Engineer

OIL REFINING as it is practiced at present is of comparatively recent origin. The petroleum industry has made wonderful progress in the last few years, but due to the past abundance and relative cheapness of the raw material as compared with the finished product and the general tendency toward making rather than saving money the average refinery practice leaves much to be desired in efficiency. As a whole the industry does not utilize the scientific and engineering data developed and proved in similar operating phases of other industries. This is particularly true for the thermophysics of refining.

Each refining operation from the crude down to the paraffine or asphalt depends on the thermal treatment to which the material is subjected. The still is the starting point of all refinery operations, and can be compared to the digestive tract of the human body. The material leaving the still determines the subsequent treatment and the final as well as the intermediate products. On the other hand, since the fuel bill is one of the main items of production costs, the commercial merits of the process are mainly determined by the still. Yet in the average refinery the still proper is the least developed of all the units. In most cases it

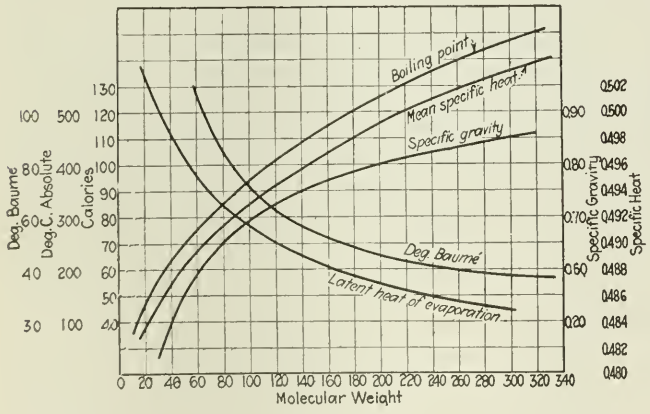

FIG. 1—PROPERTIES OF PARAFFINE HYDROCARBONS

is built on tradition, or on a pet superstition of the practical operator. The result is that, although a still is in its basic principles a boiler where the material is heated to vaporize the different constituents or cuts, the average thermal efficiency of most of the stills is around 20 per cent as compared with 75 to 80 per cent in the modern boiler.

High thermal efficiency is not the only requirement in still practice. The heat developed in the still must produce a certain thermochemical effect upon the oil, and since oil is very susceptible to thermal treatment, both the quantity and the quality of the heat must be such as strictly to meet the conditions favorable to the desired treatment. These conditions are determined by the balance sheet of the operation, which must be the starting point in the design of a refinery unit.

Fig. 1 shows the thermal properties of paraffine hydrocarbons, plotted against molecular weight.[1] Most petroleum products are a mixture of these hydrocarbons, and since any mixture of members of a homologous series has the properties of the member having the average characteristics of the mixture, the thermal properties of any petroleum product can be determined with an accuracy sufficient for all practical purposes.

After the balance sheet is completed the conditions affecting the application of the heat to the oil must be fully considered.

Working Temperatures

The working oil temperatures of straight (non-cracking) distillation are not over 450 deg. F. Since most of the distillation processes employ heat exchangers to preheat the incoming oil by the stored heat of the residue, the working range of a still is really between 150 and 450 deg. F. This is a slightly higher range than that of a boiler using a hot water heater. Yet principles of boiler design and operation cannot be successfully applied in their entirety to stills.

Water is a uniform liquid that does not break up chemically, unless the vapors are heated to 2,500 deg. C. Oil is a complex mixture, very susceptible to decomposition on heating. The thermal capacities of water and oil are also quite different. The total heat content of 1 lb. of saturated steam at 100 lb. pressure is in round figures 1,190 B.t.u., while that of oil is around 240. The specific heat of oil is less than half that of water. Therefore, when the still is operated as a boiler it is very easy to "force" the still and overheat the oil. In nine cases out of ten it is the local overheating that is responsible for carbon troubles, burnt-out bottoms, burst pipes, low yield, inferior products and many other things usually blamed either on the material treated or the subsequent operations.

Types of Stills

Since the working temperature range is the only difference between a straight and a cracking still, in matters of design the stills must be grouped with reference to their types rather than uses.

All stills can be divided into two main types: Cylindrical or conventional stills, and tube stills. Cylindrical stills are the left-overs of batch distillation. Inherently they cannot be efficient as a continuous apparatus, are troublesome in operation, have a tendency to burn out, need frequent cleaning and due to the

[1]Latent heat of vaporization after Trouton, Van't Hoff and Lagerlöf. Mean specific heat after Karawaieff.

large amount of oil heated simultaneously are a source of unnecessary hazards. The tube stills are of comparatively recent development but are today displacing the cylindrical type. The principles of design outlined in this article are, therefore, applicable mainly to tube stills.

The first requirement of a still is the absence of thermal shock to the oil—that is, a *gradual and even bringing up of the whole body of oil to the desired temperature, at a rate that does not exceed the thermal capacity of the oil and the heat conductivity of the container.* The rate of heat transfer $Q = \theta_m K$, where θ_m = mean temperature difference between the gases of combustion and the oil and K = coefficient of heat transfer.

$$\theta_m = \frac{\theta_i - \theta_f}{\log_e \frac{\theta_i}{\theta_f}}$$

where θ_i is the initial temperature difference and θ_f the final temperature difference between the gases of combustion and the oil. Therefore, θ_m will be larger the smaller is the ratio of $\theta_i : \theta_f$—that is, when the initial and the final temperature differences are approaching each other. This is true when the hottest gases come in contact with the hottest oil, or the flows of the gases and the oil in the still are counter-current.

Character of Flow

Fig. 2 shows graphically the difference between concurrent and counter-current flows. T_{GI} is the temperature of the incoming gases; T_{GL} is the temperature of the gases leaving the furnace; T_{OI} is the temperature of the incoming oil and T_{OL} is the temperature of the oil leaving the furnace; θ_{m_1} is the mean temperature difference for counter-current flow and θ_{m_2} that for concurrent flow. By assuming $T_{GI} = 750$ deg. F. (probably ideal for topping); $T_{GL} = 450$ deg. F.; $T_{OI} = 200$ deg. F.; $T_{OL} = 400$ deg. F.; θ_{m_1} and θ_{m_2} will become 297 and 208 deg. F., respectively.

This means that the same still with the same temperatures of the gases of combustion and the oil will heat 42.5 per cent more with counter-current than with concurrent flow, and do it much more uniformly. With concurrent flow the rate of heating at the beginning is about 2½ times as intensive as at the end and if the still does any heating at the end, the oil is overheated at the beginning of the cycle. That this is true in practice is evidenced by the fact that it is the lower tubes with the supposedly cooler oil that plug up or burn out in the average tube still.

The coefficient of heat transfer K depends mainly on the velocity of the fluids. The general formula[2] for two fluids both in motion is K (in calories per sq.m. per deg. C.) $= \dfrac{1}{\frac{1}{a} + \frac{1}{b} + N}$ where $a = 300 + 1{,}800\sqrt{v_1}$; $b = 2 + 10\sqrt{v_2}$; v_1 and v_2 are the respective velocities of the colder and hotter fluids in m. per sec.; N, for iron ¼-in. thick[3] = 0.0014.

Therefore, a still will have a much greater capacity if smaller tubes are used and if a large volume of low temperature gases, rather than a smaller volume of hotter gases, is passed through the heating chamber. Counter-current flow increases the relative velocity of the fluids and permits the use of very low temperature gases. This is another argument in its favor. The use of smaller tubes will not only increase the heat transfer per square foot of heating surface but by increasing the heating surface per unit and cross-section will allow for the same amount of heat to be

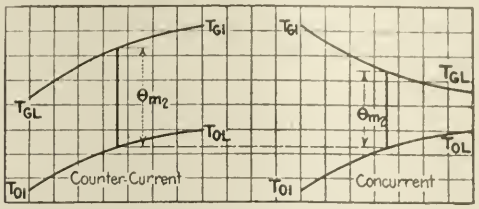

FIG. 2—CHARACTER OF FLOW AND RATE OF HEATING IN A COIL STILL

delivered to the oil at a lower mean temperature difference. As to the possibility of the smaller tubes plugging up, mild temperatures within the furnace thus made possible will eliminate the chances of overheating and remove the main cause of the trouble.

Drop in Gas Temperatures

Since counter-current flow and high velocities are essential for efficient application of heat, the coil still is the better of the two when compared to the header still, particularly if the coil still is overfired. It is a law of nature that cold gases travel down and hot gases go up. In an overfired furnace this natural tendency is assisting the proper flow of the gases of combustion. Even if it is assumed that the header still be fired at the exit header and baffled transversely so as to obtain a strictly counter-current flow of the oil and gases of combustion, the rate of heat transfer will not be as uniform as shown in Fig. 2, which is true for an overfired coil still. There is a sudden drop of temperature of the gases of combustion on both sides of the baffle. At the tubes in the center of the bundle with three baffles in the furnace this drop is one-quarter of the total drop of temperature of the gases. Fig. 3 shows this drop and the effect it has on the rate of heating of the oil.

The velocity of the oil in the header still is lower than in a coil still having the same number of tubes, since it provides a much larger section for the passage of oil than a coil made up of pipe of the same diameter.

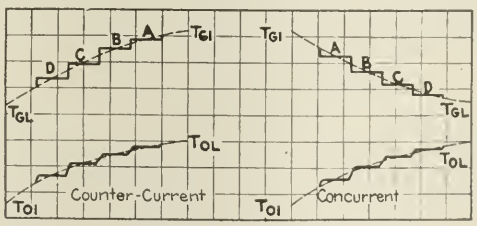

FIG. 3—CHARACTER OF FLOW AND RATE OF HEATING IN A HEADER STILL
Dotted lines are mean temperatures.

This means a lower heat transfer and therefore either a greater heating surface or higher furnace temperatures to produce the same results, which is another disadvantage of the header still, unless means are provided to recirculate the oil within the still proper, as is successfully done in at least one process.

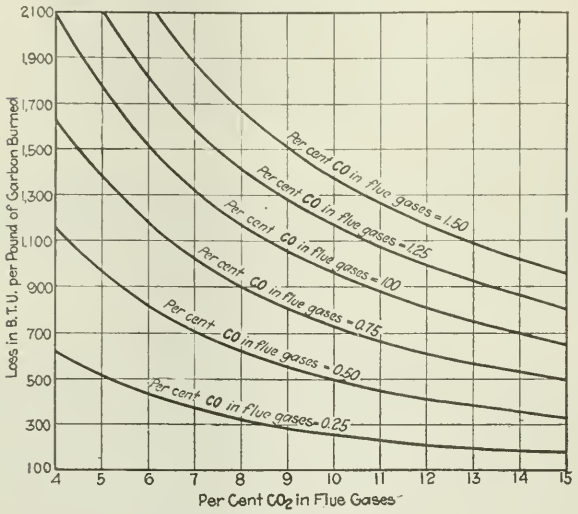
Since proper application of heat depends closely on the correct generation of the heat, in designing a still

[2]Peclet.
[3]Landolt-Börnstein "Tabellen."

full consideration must be given to the principles of efficient heat generation.

The greatest need of the refining industry at present is the introduction of combustion engineering which deals with these principles. The ceramic and the metallurgical industries owe no small part of their progress to the scientific application of combustion engineering, and to these two industries belongs the credit for the development of the modern science and practice of combustion.

The first requirement for efficient generation of heat



Loss in B.T.U. per Pound of Carbon Burned
Per Cent CO₂ in Flue Gases
Per cent CO in flue gases = 1.50
Per cent CO in flue gases = 1.25
Per cent CO in flue gases = 1.00
Per cent CO in flue gases = 0.75
Per cent CO in flue gases = 0.50
Per cent CO in flue gases = 0.25

FIG. 4—LOSS OF HEAT DUE TO INCOMPLETE COMBUSTION

From "Steam, Its Generation and Use," Babcock & Wilcox Co.

is the proper proportioning and mixing of fuel and the air. Table I shows the theoretical amount of air necessary for the combustion of different fuels. Insufficient air will give incomplete combustion and a loss of efficiency. The loss of heat due to incomplete combustion is about 100 N B.t.u. per lb. of carbon content where N is the CO percentage of the combined CO and CO_2 gases. Fig. 4 shows the losses through incomplete combustion.

Excess of air is just as detrimental as lack of it. Fig. 5 shows the loss of heat in the flue gases due to excess air and the B.t.u. contents of the fuel and air mixture for different fuels at different excess coefficients. A 100 per cent excess (common practice in many refineries) will result in a loss of 25 per cent of the total heat developed if the furnace temperature is 1,000 deg. F.

Mixing Combustion Gases

The importance of proper mixing is shown in curves *CD* and *EF* of Fig. 6. Curve *CD* represents *in hours* the time-temperature curve of complete oxidation of carbon at different temperatures when both carbon and oxygen are at rest and was obtained by heating charcoal in an atmosphere of oxygen. Curve *EF* shows *in seconds* the time necessary for complete combustion of carbon when the carbon and air are mixed and constantly agitated. The coefficient of agitation is determined by the size of the particles and the velocity of impact. Unity is the ideal as yet not obtained in practice even with gaseous fuel.

The best of gas and gasified oil burners have a coefficient of 0.90 to 0.95. Atomizing low-pressure oil-burners seldom exceed 0.80. High-pressure burners have a still smaller coefficient. The reason for this is

TABLE I—AIR REQUIRED FOR COMBUSTION OF DIFFERENT FUELS

Fuel	Heat Value B.t.u. Per Cu.Ft.	Theoretical Air Required, Cu. Ft. Per Cu.Ft.

Gasoline 0.704 sp.gr.	18,500	193.5
Fuel oil 0.939 sp.gr.	18,183	178

Note: For designing purposes when using liquid fuel assume 140,000 B.t.u. per gal. and an air consumption of 25 cu.ft. per minute per gal. per hour.

the great initial velocity of the mixture, which, due to the difference in size and specific gravity of the particles of the air and the oil, produces a difference in inertia of the particles as soon as the mixture leaves the nozzle, with the result that in cross-section the flame consists of rings of different chemical composition and different temperatures.

Velocity of Combustion Gases

Another important consideration is the velocity of gases of combustion both at the nozzle and after ignition. At the nozzle the velocity must be as close as possible to the velocity of propagation of flame, which is different for different fuels and is about 300 ft. per second for low-pressure gasified fuel. With the proper

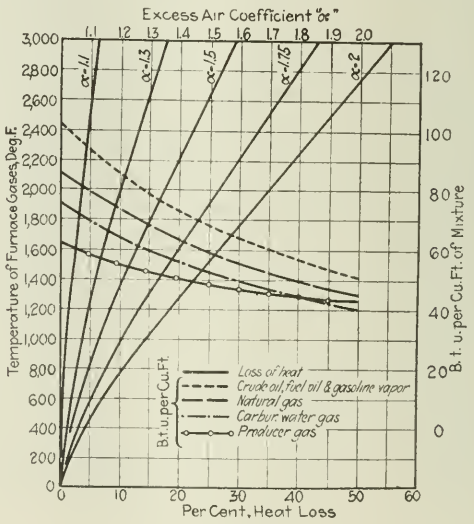

FIG. 5—EXCESS AIR AND FURNACE PERFORMANCE

After Ulbright & Torrance and Richardson.

nozzle velocity there will be no back firing, no flame pulsation and no hard smoky starting up of the furnace, so common in many oil-fired furnaces.

Velocity of the products of combustion within the combustion chamber determines the actual zone of combustion irrespective of the intentions of the designer, and should be such that complete combustion, as determined by the necessary time element from Fig. 6, occurs before the gases enter the zone of actual heating.

The last and the most important factor of efficient heat generation is the design of the combustion chamber proper. There is a certain fixed ratio between combustion space and the amount of fuel burned for each temperature, the ratio being more or less independent of the fuel burned. Fig. 7 shows the maximum actual

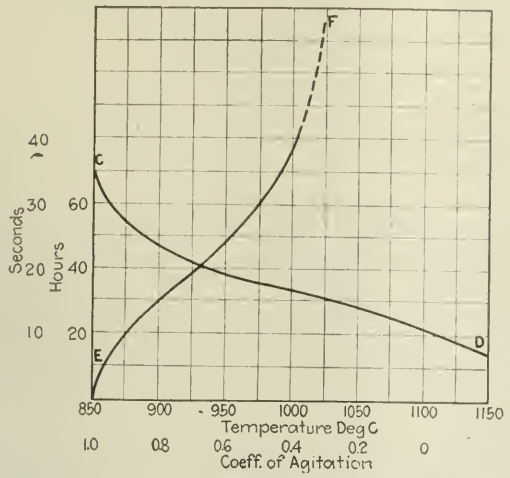

FIG. 6—IMPORTANCE OF PROPER MIXING
Curves after Reid & Wheeler and Le Chatelier.

obtainable temperatures for different ratios of B.t.u. per cubic foot of combustion space, as obtained in a certain furnace tested by the author. The curve is characteristic for all furnaces and depending on the ratio of the fixed losses through the combustion chamber (radiation, leakage) to the total heat developed is either raised or lowered parallel to itself.

Recirculation

A new feature in combustion chamber design is recirculation of the gases of combustion after ignition. Although the least known, this feature is the most beneficial, since it accomplishes secondary mixing of the ignited gases and neutralizes the effects of concentric flame composition; it dilutes the atmosphere within the combustion chamber, and therefore eliminates the existence of hot spots in the path of the flame; the whole combustion chamber is thus converted into a mass

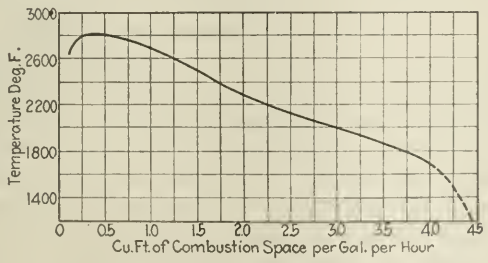

FIG. 7—COMBUSTION SPACE AND MAXIMUM OBTAINABLE TEMPERATURE

of infinitesimal centers of combustion, each point within the chamber as well as on the surface of the walls acting as a source of generation of heat energy. Recirculation further automatically regulates the time element and the velocity of products of combustion, by reducing the travel of gases in a straight line, helps to satisfy the time element necessary for complete combustion and the volumetric relations of the combustion chamber to produce the desired temperature. The recirculating feature permits transformation of the high temperature heat of the fuel into heat of a temperature required for the distilling operation without the losses due to excess air which is commonly employed for the purpose.

Fig. 8 shows a combustion chamber having the recirculating feature incorporated in its design and the effect it has on the path of the gases. The amount of recirculation is determined by the distance of the recirculating baffle *B* from the wall by the size of the opening *O* in the baffle, by the nozzle velocity of the burner, by the velocity of the gases from the combustion into the heating chamber and the mean gas velocity through the complete furnace.

Correct Still Design

Fig. 9 shows the time temperature curve of an automatically controlled oil-fired heat-treating furnace built according to the principles of combustion engineering enumerated above. The maximum variation is ± 5 deg. F., with the minimum approaching ± 2.5 deg. F. The same results can be accomplished with a still if

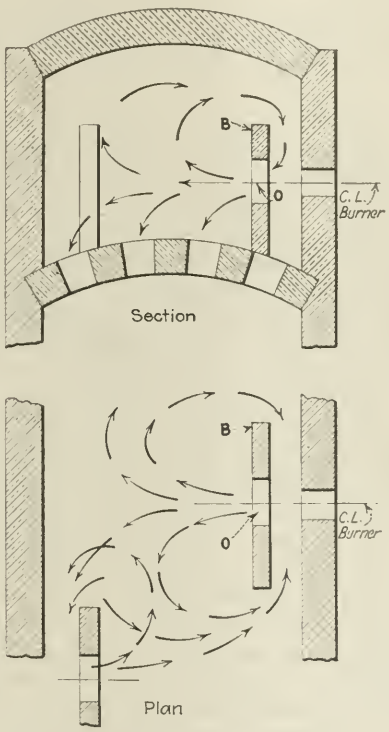

FIG. 8—COMBUSTION CHAMBER WITH RECIRCULATING FEATURE

in the design it is considered a delicate heating apparatus and not just so many bricks, a few buckstays and a burner, all assembled so as to produce "heat" and accommodate a container decided upon mostly on account of its having worked somewhere else. The results obtained in a scientifically designed still will in a very short time compensate for the extra care in designing and the additional cost of installation. This is particularly true for cracking stills.

There is a very delicate equilibrium between the straight and cracked phases of petroleum products depending on temperature and pressure. The aim of successful cracking is to make the transformation of the straight into the cracked phases as distinct and simultaneous as possible and all efforts are bent to separate the zone of heating from the zone of actual

cracking by comparatively sudden changes of temperature or pressure. All other conditions being equal, the more uniform is the heating the less are the chances for the zones to overlap and the less the possibility of premature cracking within the heating zone. It is the uneven heating within the cracker that is responsible for the fact that there are no truly continuous cracking processes, and that a run of 90 to 100 hours is quite an accomplishment. The average run is around 48

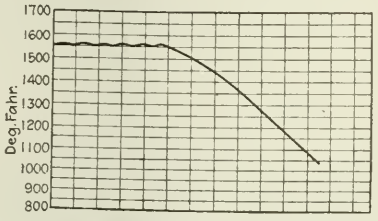

FIG. 9—TEMPERATURE CONTROL OF OIL-FIRED HEAT-TREATING FURNACE

hours, after which period the plant is shut down, often as far as the dephlegmator, to be cleaned of carbon deposits.

An Instance in Operation

The writer knows of a "demonstration run" on a cracking process when a 4-in. pipe was completely plugged up in a few hours on a stock that was treated satisfactorily the previous week. It was a forced run for production. A small portion of the tube became hot, causing a local overheating, premature cracking, deposition of carbon, a decrease in heat transmission of that portion, a further overheating, more cracking, more carbon, and so on. Yet there were twelve good pyrometers on the system and an experienced and conscientious operator in charge. The fault was in the design of the cracker, or rather the construction, since no principles of design were used. Its general arrangement, the combustion chamber, the number and size of tubes were decided upon for the only reason that "it worked" somwhere else under similar conditions, with "pretty good results"—that is, for about 48 to 72 hours with a fuel consumption of over four times the theoretical. It worked, but had a tendency to develop all kinds of trouble at the wrong moment.

Later a firm of consulting engineers was called upon to develop a commercial unit for the process. The engineers worked under a handicap. They had to accept a certain "proved" (but from the combustion engineer's point of view questionable) construction of the cracker. They also had to take for granted certain "fundamental" laws of standard refinery practice. In spite of all this, by paying attention to the causes and not the manifestations of certain phenomena and by utilizing experience obtained in similar branches of other industries, they evolved a unit that made a continuous 18-day run with a fuel saving exceeding the best hopes of the customer.

Conclusion

Such success obtained teaches a lesson that should be taken into consideration by the refining industry. All process industries have many common fundamental operations, even if they are totally different in the finished product. Usually each of these operations is brought to a relatively high degree of perfection in some industry and the industries that make no secrets of their accomplishments have the largest number of perfected operations to their credit.

Oil refining is as yet the most isolated of all the process industries. Except for the laboratory, where there are many chemists that have had experience in other fields, the refineries are too much dependent on inbred talent. The result is seen in the comparison between the chemical and the operating phases of refining. While a large number of new products were developed in recent years, the mechanical features of the methods of production are the same, the changes being rather additions to and not improvements of the practices of the past.

There are without any question many refinery operations that could be greatly improved by adaptation or by a pooling by different plants of experiences in the general operating features. A "give and take" policy as demonstrated in metallurgy, for example, would not only help to abolish the existing troubles, but would raise the standard of operating efficiency and result in better products at less cost.

Chicago, Ill.

Oxygen in Iron Melted Under Air or Gas Flame

A series of melts of electrolytic iron have been made at the Bureau of Standards under air in the induction furnace with additions of varying amounts of metallic calcium as a deoxidizing agent. The addition of calcium up to 0.2 per cent did not increase the soundness of the chilled cast ingots; the amount of oxygen (determined by the Ledebur method) in the ingots was practically the same throughout the series regardless of the amounts of calcium added. The average oxygen content of the calcium treated melts was approximately 0.23 per cent. Pure electrolytic iron melted under the same conditions contained 0.21 per cent oxygen. All the above melts were made in the open under still air. Electrolytic iron melted under a jet of air contained only slightly more oxygen than when melted under quiet air—namely, 0.24 per cent. Ingot iron melted under similar conditions under quiet air and under an air jet contained, respectively, 0.21 and 0.26 per cent oxygen. Ingot iron melted under the oxidizing flame of a gas blast-torch contained 0.26 per cent oxygen, the same as when melted under a jet of air.

Constituents of High-Speed Steel

Tests made at the Bureau of Standards appear to show that there are at least three different constituents present among the imbedded globules or particles in the specimen of high-speed steel, in the "as received from the mill condition," although their nature is unknown. This fact was determined by "sequence etchings" with (1) dilute NH_4OH solution together with a weak electric current, the specimen being made positive pole; (2) 2 per cent alcoholic solution of HNO_3; (3) boiling sodium picrate, and (4) Murakami's reagent (solution of potassium ferricyanide and sodium hydroxide) at boiling temperature.

"Sequence etching" means the etching with two or three reagents in successive order without any repolishing of the section between the etchings, and the taking of micrographs after each etching at the same spot in the microsection in order to note any changes in microstructure produced by the last etching as compared with that developed by the preceding etching reagent.

The System Furfural-Water*—I

A Study of Its Properties With Reference to Their Commercial Application in the Production of Furfural —Boiling Point and Density of Furfural—Density of Furfural-Water Solutions—Solubility Data—Boiling Point Curves—Temperature-Composition Diagram

By GERALD H. MAINS
Color Investigation Laboratory, Bureau of Chemistry

IN THE METHODS of preparation of furfural given in the literature, pentosan- or pentose-containing substances are digested with dilute hydrochloric or sulphuric acids, and the distillate, consisting of a slightly acid aqueous solution of furfural, is collected. The furfural is then concentrated by extraction with ether or other solvents, or by distillation. Several authors note that furfural can be quite readily separated from water by distillation,[1] the greater part of the furfural coming over in the first portions of the distillate, from which, being only partly miscible with water, it can be readily separated. Some recent French patents provide for column distillation during the manufacture of furfural.[2] The author has found in the manufacture of furfural on a small factory scale that the separation of furfural from its aqueous solution by fractional distillation is a very short and effective method. There are, however, no published data, exact or otherwise, available on the relative compositions of distillate and solution, boiling point curves or condensation curves.

Distillation of Partly Miscible Liquids

When a mixture of two partly miscible liquids is distilled, as long as two layers are present the boiling point will remain constant and a distillate of constant composition will be formed. This mixture boils at a temperature below the boiling point of one of the components and often below that of either. When distillation has proceeded to the point where one of the layers disappears, the condition is one of a simple solution of one substance in another, and distillation continues with varying composition of distillate and rising temperature, until one of the components is entirely removed and the boiling point of the remaining component is reached.

The system furfural-water is an example of this class of partly miscible liquids. Furfural is somewhat soluble in water. When more furfural than will go into solution is added to water, two layers are formed, an upper water layer containing some furfural in solution and a lower, heavier furfural layer containing some water. Upon distilling a furfural-water mixture containing only a small proportion of the furfural layer, the boiling point will be slightly lower than that of water and the distillate will be of constant composition until the furfural layer has disappeared. The boiling point will then rise, and the concentration of furfural in the liquid in the distilling flask will decrease more rapidly than in the distillate until practically pure water is left in the still. On the other hand, starting with a furfural-water mixture in which the furfural layer predominates, the concentration of water will be continually greater in the distillate than in the liquid in the still until the point is reached where for practical purposes it may be considered that all of the water has been separated and the residual liquid in the still consists of pure furfural.

It may be here pointed out that the liquid composed of furfural and water at room temperature is a solution of furfural in water when only a small amount of furfural is present, and a solution of water in furfural when only a small amount of water is present; and that between these two extremes two layers having a distinct boundary and differing from each other in composition are present. As the temperature is increased, the range of furfural-water concentrations throughout which the two layers occur becomes smaller, and at the same time the concentrations of the layers vary and approach each other. The liquid system furfural-water is then a solution over part of the range of composition, and over the remainder of the range is a mixture of two solutions, with no fundamental difference between them except concentration. For convenience, and with the theoretical justification already outlined, the liquid composed of furfural and water will be referred to throughout this paper as a solution.

Experimental

In order to study the system furfural-water, especially with respect to the corresponding compositions of solution and distillate (the solution in the flask being the liquid phase and the distillate the condensed vapor phase), an accurate method of determining the amount of furfural present was needed. The standard phloroglucin analytical method[3] was tried, but it does not give results of sufficient accuracy for an investigation of this type. In a number of determinations on known solutions, in spite of all precautions, there was a variation of from 2 to 5 per cent from the true value. Several investigators have recognized the inaccuracies of the method and published data of others show variations of this order.[4] For determinations of small amounts of pentosans in plant materials the method may be sufficiently accurate (far more so than the preliminary treatment to obtain the furfural), but it will not serve for accurate work on pure solutions. It is, moreover, very time-consuming. The precipitation of furfural as the phenylhydrazone is subject to the same objections.

Investigators who have studied the boiling point and condensation point curves of alcohol-water solutions

have used density tables to determine composition, and in view of the fairly wide difference in density between furfural and water, this method gave promise of accuracy and simplicity. Schwers,[5] with an entirely different end in view, has determined the density of certain solutions of furfural and water at various temperatures. His data cover only three dilute solutions, and the density of his original furfural does not agree well enough with the determinations of the author to permit the use of Schwers' figures for the solutions. Accordingly a number of known solutions were prepared and the densities determined.

Boiling Point of Furfural

In any such determination of the densities of water solutions of a certain substance, the physical properties of the substance used, in this case furfural, are of the utmost importance. The furfural used in these experiments was made by digesting corn-cobs with sulphuric acid (30 per cent). The crude furfural was redistilled with the addition of 2 or 3 g. of sodium carbonate. A colorless product was obtained, and the fraction boiling between 159 and 161 deg. C. (uncorrected) was collected. Of this product 800 c.c. was redistilled, and the middle portion, 400 c.c., boiling constant within 0.1 deg. was collected.

The corrected boiling point of a sample of furfural made by this method, as read by an Anschutz thermometer suspended in the vapor and checked against one recently calibrated by the Bureau of Standards, was 161.8 deg. C. at 762.5 mm. (barometer fully corrected and checked against U. S. Weather Bureau barograph record). The vapor pressure curve for furfural (determined by H. Wales and the author, and to be published shortly) gives the correction value, 1 mm. equals approximately 0.05 deg. C. Using this value, the corrected boiling point at 760 mm. would be 161.7 deg. C.

A second lot of furfural which was used in a number of the experiments was found to have a boiling point of 161.8 deg. at 762.2 mm., or 161.7 deg. corrected to 760 mm. The corrected boiling points of other lots, as determined by an ordinary thermometer with long exposed stem and with consequent inaccuracies in the large stem correction, varied from 161.1 to 161.5 deg. C.

An especially pure sample was prepared as follows: To a portion of redistilled furfural obtained from corn-cobs was added saturated sodium bisulphite solution until the mixture became sirupy in consistency. It was then chilled. At approximately 15 deg. C. white needle-shaped crystals of the furfural sodium bisulphite addition compound separated out, the entire mass becoming nearly solid. The mother liquor was drained off on a suction filter and the crystals washed with ether and dried. The furfural was set free by adding a saturated solution of sodium carbonate. By fractional distillation a concentrated furfural-water solution was obtained and the furfural layer separated off. The wet furfural was then distilled, and, after the water had separated, the portion boiling within 0.1 deg. C. was collected. This sample was redistilled and the boiling point determined with an Anschutz thermometer (recently calibrated by the Bureau of Standards), totally immersed in the vapor and having the bulb covered with cotton batting to insure perfect condensation. The temperature rose rapidly to 161.7 deg. C. and remained constant during the distillation. The corrected barometer reading was 760.9 mm., so that the corresponding temperature correction is less than 0.05 deg. These determinations indicate the true boiling point of pure furfural to be 161.7 deg. C. at 760 mm.

Of the boiling points of furfural previously given in the literature, ranging from 160 to 168 deg., only those of Schiff[6] (160.5 to 160.7 deg. at 742 mm.) and Brühl[7] (161.4 to 161.8 deg. at 754.5 mm.) appear to have been obtained with any great degree of accuracy. Corrected to 760 mm., their results are: Schiff, 161.4 to 161.6 deg. C.; Brühl, 161.7 to 162.1 deg. C. It may be pointed out that with the small quantities used by them it would be difficult to purify the liquid by one distillation, and that in the case of Brühl's work the boiling point range indicates an appreciable impurity. The presence of a small amount of methyl furfural, a quite common impurity, would account for the higher boiling point.

Density of Furfural

The density of the freshly distilled sample of furfural, purified by transforming into the sodium bisulphite compound and recovering, was determined by means of a Sprengel type pycnometer. Because of the high heat conductivity and high coefficient of expansion of furfural the density values could be determined with accuracy only to the fourth place. The observed values corrected to vacuum standard were $D^{20}_{4} = 1.1598$ and $D^{25}_{4} = 1.1545$.

Using specific gravity bottles, as described hereafter, for the furfural-water solutions, density determinations were made on other lots of furfural at various intervals of time. Lot 21.1, from which the furfural-water solutions for the density determinations were made, was 22 days old at the time of making up the solutions. Its density values were $D^{20}_{4} = 1.1610$ and $D^{25}_{4} = 1.1556$. After standing 40 days in a cork-stoppered brown glass bottle the density was $D^{20}_{4} = 1.1631$, an increase of 0.0021. After standing 52 days, the value was $D^{25}_{4} = 1.1586$, an increase in density of 0.0030. This increase in density is probably due to a slow polymerization of the furfural upon exposure to light and air. It is accompanied by a pronounced darkening in color, the liquid becoming a dark brown. Berthelot[8] has described this polymerization and the resulting compound.

TABLE I—OBSERVED DENSITY OF FURFURAL-WATER SOLUTIONS

Per Cent Furfural by Wt.	Density (Referred to Water at 4 Deg. C.) 20 Deg. C.	25 Deg. C.	Per Cent Furfural by Wt.	Density (Referred to Water at 4 Deg. C.) 20 Deg. C.	25 Deg. C.
.....	0.99823	0.99708	4.154	1.00589	1.00448
1.000	1.00009	0.99869	6.036	1.00953	1.00803
1.913	1.00165	1.00041	8.047	1.01308	1.01152

Since the density of furfural increases upon standing, the densities reported in the literature are of little value beyond the second decimal place, because the periods elapsing between the preparation of the samples and the determinations of their densities are not given. The density at $^{20}_{4}$ is given by Brühl[9] as 1.1594, and by Schwers[10] as 1.1593. Calculations from the formula of Jaeger and Kahn[11] ($D = 1.1851 - 0.001176t + 0.00000096t^2$) give values at 20 deg. C. of 1.1620 and at 25 deg. C. of 1.1563. The criticism of the values of Brühl and Schwers is that the furfural used was not collected within a close enough boiling point range to

be of absolute purity. Information as to the purity of the furfural used by Jaeger and Kahn is lacking. In order for density to serve as any criterion of the purity of furfural, the determination must be made on a freshly distilled sample.

Density of Furfural-Water Solutions

The furfural used in making up the solutions was lot 21.1, $D^{20}_{4,\,Vac.} = 1.1610$, $D^{25}_{4,\,Vac.} = 1.1556$.[12] The furfural and water were weighed into tared flasks, and the densities of the resulting solutions determined by the use of 30 and 50 c.c. specific gravity bottles having ground-in thermometers. These thermometers were calibrated to 0.1 deg. C. against a thermometer recently calibrated by the Bureau of Standards. The densities (referred to water at 4 deg.) were determined at 20.0 and 25.0 deg. C., and were corrected to a vacuum standard. The value in each case is the mean of determinations made with two specific gravity bottles, except for the 6.036 per cent solution, where it represents the mean of six determinations, two with each of three specific gravity bottles. The probable error in density for this solution at 20 deg. is ±0.00002, and for 25 deg. is less than ±0.00001. The observed density values are given in Table I.

66	12.5	96	84.5
92	17.0	....	.. .

The composition of solution, expressed as percentage of furfural by weight, was plotted against the density on a large chart and the values were found to lie along a straight line. A variation of 0.01 per cent in furfural concentration produces a density change of nearly 0.00002, so that by using ordinary specific gravity bottles and allowing a probable error of ±0.00004, the concentration of furfural can be determined within ±0.02 per cent without taking any extraordinary precautions except that the room temperature must not exceed by any appreciable amount the temperature at which the density is determined. In Table II the densities read from the curve are given to the nearest 0.0001 for composition intervals of 0.2 per cent furfural.

Solubility Data

Owing to the possibility of separating furfural from water by decantation of the two layers, solubility data at various temperatures become of importance. Rothmund[13] has studied the mutual solubilities of furfural and water in relation to their critical solution point. Since his determinations were not made at constant pressure, but at the vapor pressure of the solution, and as data on the purity of the original furfural are not given, the solubility curves have been determined by the author for atmospheric pressure conditions.

The method followed was to place layers of furfural and water in a flask, bring to approximately the desired temperature, stopper the flask, shake violently 100 times, let the two layers separate, and pipette samples from each. The temperature was taken just as the shaking was completed, and except at room temperatures was read only to the nearest degree. The pipetted samples were necessarily taken as soon as the two layers had separated and before cooling had started any further separation. In determining the solubility in the aqueous layer it is important to have a very thorough shaking, on account of the slow rate of solution of furfural when near the saturation point. Globules of furfural may be present in the bottom of the solution when the solution is far from being saturated. Tests at room temperature indicated that the method adopted, violent shaking 100 times, was sufficient to obtain complete saturation.

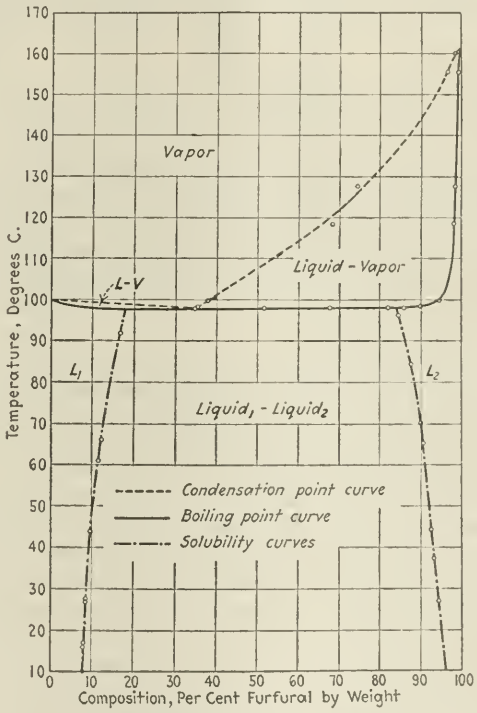

FIG. 1—TEMPERATURE-COMPOSITION DIAGRAM FOR THE SYSTEM FURFURAL-WATER

[12] These values are about 0.001 higher than the density values for freshly distilled furfural. This difference would cause an error in the dilute solutions, however, of only 0.00001 for the 1 per cent solutions, and of less than 0.0001 for the maximum concentration at saturation (8 to 9 per cent furfural at ordinary temperatures).

[13] Rothmund, *Z. Phys. Chem.*, vol. 26, p. 454 (1898)

The concentration of furfural in the pipetted samples was determined by measuring the density of the original or diluted sample, and reading the percentage of furfural from the composition-density chart. In diluting concentrated solutions the aim was to get a solution of 6 to 8 per cent concentration, if possible, in order to avoid error by having a small multiplying factor.

The observed data are given in Table III. The agreement of the three determinations at room temperature indicates the degree of accuracy of the results.

The temperature-solubility curves for both aqueous and furfural layers, plotted from the observed values, are shown in Fig. 1. The values for the furfural layer run in fairly close agreement with Rothmund's data, reaching a maximum variation of 0.5 per cent below his values. The values determined for the water layer are, however, much higher than his, the difference increasing from 0.6 per cent at 10 deg. C. to 2.5 per cent at 65 deg. C., where his figure is 9.9 per cent, as compared with the present observation of 12.4 per cent. The difference decreases thereafter until at the boiling point they are within 0.5 per cent of each other again. There can be no question that all of the higher amount is in solution. The effect of pressure on solubility can scarcely account for the wide difference between Rothmund's figures and those given here. Since his determinations were made by observing the temperature at which the solution contained in small tubes turned from turbid to clear and vice versa without thorough shaking, it is possible that complete saturation did not exist, hence the low results.

TABLE IV—MUTUAL SOLUBILITY OF FURFURAL AND WATER
(Atmospheric Pressure)

Temp., Deg. C.	Per Cent Furfural By Wt. Water Layer	Furfural Layer	Temp., Deg. C.	Per Cent Furfural By Wt. Water Layer	Furfural Layer

* Boiling point of system when both layers are present.

For convenience the solubility data for 10 deg. intervals as taken from the curves are presented in Table IV.

Boiling Point and Condensation Point Curves

Observations made during the manufacture of fairly large quantities of furfural and the concentration of furfural from dilute solutions by fractional distillation indicated that two-layer solutions of furfural and water boiled at approximately 2 deg. below the boiling point of water. To study the change in boiling point with composition of solution over such a small range of temperature could not give satisfactory results by using the process of distilling in a flask and recording the temperature with an ordinary thermometer. A method was devised in which two similar 500-c.c. distilling flasks were used. with Beckmann thermometers, graduated to 0.01 deg. C., inserted in each flask so that the scale began just above the cork stopper and the bulb was just below the side tube. In one of the flasks distilled water was slowly distilled, and, simultaneously and at the same approximate rate, the furfural-water solution under investigation was distilled in the other. The Beckmanns were calibrated against each other, using distilled water in each flask.

To determine the boiling point of a solution, the procedure was as follows: Furfural and water were weighed into the flask to make a solution of the required strength and a volume of 250 to 300 c.c. The Beckmann was then inserted and the flask contents slowly heated until the first drops of distillate came over. As soon as free distillation was taking place a water-cooled weighed receiving flask was placed over the side tube, and the temperature read. The temperature was then read every minute for 8 minutes as a rule, and simultaneous readings were made of the temperature indicated by the Beckmann in the adjoining flask, in which distilled water was boiling under similar conditions, The average reading of the first Beckmann subtracted from that of the second, with the calibration correction and scale corrections considered, gave the depression of the boiling point of water caused by the furfural in solution. This subtracted from 100.00 deg. C. then gave the average boiling point of the solution at 760 mm. The distillate (15 to 20 g.) was weighed, diluted with a weighed volume of water, and the density determined in duplicate. From this the concentration of furfural in the distillate was calculated. The distilling flask and remaining contents were weighed, and the composition of the residue calculated. From these data the average composition of the solution during distillation was calculated. The concentration of the residual solution was also checked by density determination.

It was found that the distillate was several times as concentrated as the solution, and that above 20 per cent furfural, where two layers were present at the boiling point, the composition of the distillate was practically constant at 35 per cent furfural. A solution containing 34.7 per cent furfural boiled with a depression from the boiling point of water constant to 0.01 deg. for over 40 minutes, giving a distillate which showed the same analysis, 35.0 per cent furfural, for three different portions. The boiling point when both furfural and water layers are present is 97.90 deg. C. at 760 mm.

TABLE V—OBSERVED COMPOSITION AND BOILING POINTS OF FURFURAL-WATER SOLUTIONS

Average Comp. of Solution (Per Cent Furfural by Wt.)	*Average Comp. of Distillate (Per Cent Furfural by Wt.)	Depression From B.P. of Water, Deg. C.	Corrected Boiling Point at 760 mm., Deg. C.

* Composition of distillate not exact owing to slight fractionation taking place in neck of flask.

When the concentration of the furfural-water solution reaches 85 per cent furfural, the boiling point begins to rise and reaches 100 deg. at about 95 per cent furfural. After that it rises very rapidly, and the distillate contains a much larger proportion of water than the solution, until finally practically pure furfural is left in the flask, and the boiling point is above 160 deg. C. For these last determinations an ordinary thermometer displaced the Beckmann. The thermometer readings change rapidly during the determinations on solutions containing above 95 per cent furfural, hence the readings are probably not accurate to closer than a degree

TABLE VI—OBSERVED COMPOSITION OF SOLUTION AND DISTILLATE

(Fractionation Eliminated by Use of Heated Still Head)

3 (*a*)	3.96	20.7	. . .	. . .	. . .

except at the very end, where the distillate is practically pure furfural. As there is a 60 deg. temperature interval for a 5 per cent composition change, however, the relative accuracy is very satisfactory. The observed average temperatures and average compositions of solution and corresponding distillate are given in Table V.

The values in Table V have been plotted on a temperature-composition diagram, and curves drawn through the points give the boiling point and condensation point curves for the entire system. These are shown in Fig. 1, as well as the solubility curves before mentioned. Together they form the complete temperature-composition diagram at atmospheric pressure for the system furfural-water from 10 to 170 deg. C.

Distillate-Composition Values Determined With Heated Still Head

The method just described is especially well adapted to the determination of the boiling points of the solutions, since it provides for the condensing of small drops of the vapor upon the thermometer bulb. However, by insuring correct boiling points there is also brought about an inaccuracy in the composition of the distillate because of the partial condensation and fractionation which takes place in the upper portion of the still head.

* Saturated solution of furfural in water at 20 deg. C.
† Saturated solution of furfural in water at the boiling point.
‡ Range over which both furfural and water layers are present.

Inasmuch as this method of determining distillate composition curves is open to some criticism,[14] is was deemed advisable to use a method which would eliminate condensation errors.

For the dilute solution of furfural, which must be considered in the commercial production of furfural, the concentration of furfural in the distillate is so many times greater than that in the solution that it is important to obtain a very accurate composition curve.

These errors caused by partial condensation in the still head were eliminated in a second series of determinations by heating the still head. A lead pipe was coiled around the neck of the distilling flask, the entire neck covered with tin foil, to bring uniform heating to all portions, and then covered with layers of asbestos and cloth. A vigorous current of steam passed through the coil kept the temperature of the still head at 100 deg. C., far enough above the boiling point of the solutions in question so that no condensation took place in the still head. As before, solutions of known strength were slowly distilled in the flask, and the distillate collected in

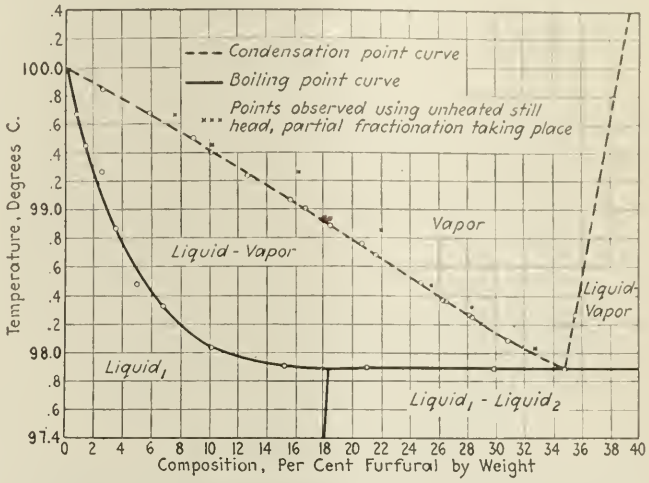

FIG. 2—TEMPERATURE-COMPOSITION DIAGRAM
Portion of Fig. 1 enlarged.

weighed, water-cooled receiving flasks. When about 20 g. of distillate had been collected, a second receiving flask was put in place and the distillation continued. The concentration of furfural in the distillate was determined from the density tables, and the average composition of the solution in the still calculated by the loss in weight. After two and sometimes three fractions of the distillate had been collected, the residual solution was weighed, and its composition checked by density determination.

With the higher concentrations of furfural not more than two samples could be collected from one run, owing to the error introduced by the tendency of furfural to polymerize after being heated for some time. Different runs gave determinations on distillate composition for the same solution composition varying only 0.2 per cent in a total of 26.5 per cent, or less than 1 part in 100. The greatest variation in values of residual solution in the flask, calculated from the original weight and the weight of distillate, and those determined by density was about 1 part in 200. The observed values of corresponding distillate and solution composition are given in Table VI. The notations (*a*), (*b*) and (*c*) in the column headed "Run No." indicate successive samples taken during the same run.

Temperature-Composition Diagram for Dilute Solutions

The data for the boiling point curve for dilute solutions were now plotted on a very much enlarged scale, and the values of distillate composition determined by the second method were plotted at the boiling point temperatures of the solutions with which they were in equilibrium. These boiling point and condensation point curves are shown in Fig. 2.

The distillate composition values, as determined by the first method where the still head was unheated and partial condensation took place, are indicated on the

[14] *Cf.* Lewis, *J. Ind. Eng. Chem.*, vol. 13, p. 169 (1921).

diagram by small crosses. It will be noted that these values are from 0.5 to 3 per cent too high. The values determined by the second method lie in a very smooth curve.

Corresponding Compositions of Solution and Distillate

The data from the curves of Fig. 2 are presented for convenience in Table VII, where, for every change of 0.5 per cent in composition of the dilute solutions, the

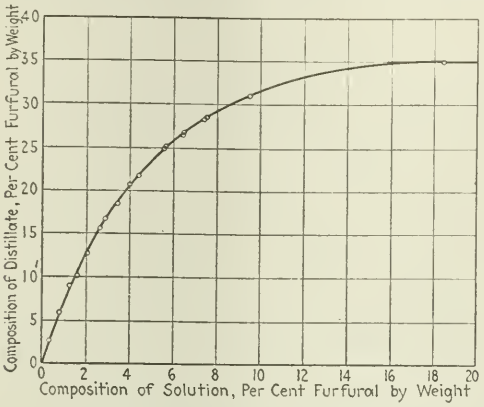

FIG. 3—CORRESPONDING COMPOSITION OF SOLUTION AND DISTILLATE

boiling point and the corresponding composition of distillate are given.

The great divergence of the boiling point and condensation point curves for this system shows why furfural can be so readily separated from water by fractional distillation. The relations between the compositions of the furfural-water solution and the distillate obtained from it are more clearly brought out by plotting the data from Table VI with composition of solution as abscissas and composition of distillate as ordinates. The solution-distillate composition diagram thus obtained is presented in Fig. 3.

Part II, dealing with the practical application of these data, will be published in a subsequent issue.

Domestic Potash Production in 1921

More than 18,200 short tons of crude potash salts containing 7,618 short tons of K_2O was produced in the United States in 1921 from domestic sources, according to the United States Geological Survey. This potash was produced at seventeen plants by fifteen companies, and about 79.5 per cent of it was extracted from natural brines. Three other companies produced considerable potash in 1921, but they have not yet returned their schedules. The annual production from domestic material was less in 1921 than in any other year since 1915.

Twenty-one plants made sales amounting to 8,907 short tons of crude material containing 3,895 short tons of K_2O, valued at point of shipment at $383,218, and twenty-four plants reported stocks on hand amounting to 26,461 tons of crude material containing 10,348 short tons of K_2O. Sales and stocks on hand are reported by several companies that did not produce potash in 1921.

The only plants that reported continuous operation during the year were several that produce potash from the dusts of cement mills and blast furnaces. The inactivity of the fertilizer market and the low price of foreign potash are given as reasons for non-production.

More Efficient Oil Refinery Apparatus Required as Competition Increases

A study of the efficiency of oil refinery equipment is being conducted at the Petroleum Experiment Station of the Bureau of Mines, Bartlesville, Okla. The typical mid-continent "skimming plant" was erected at the time of flush production in some oil field adjacent to the location of the plant and, when completed, oil was at a comparatively low price and easy to obtain. In most cases no particular attention was paid to constructing an efficient plant for the reason that those interested in building refineries of this nature were anxious to get the plant running and obtain returns on their money as soon as possible. Recently conditions have changed to such an extent that a number of these refineries have been forced to shut down because of inability to obtain crude or because they were not able to manufacture products to compete with those turned out by the larger refineries. It is believed that by a careful study of these plants the Bureau of Mines can furnish advice as to the best methods for their operation and aid in preventing enormous wastes due to inefficient equipment.

Another investigation which is to be conducted at this station relates to methods of treating petroleum products. Most of the progressive refiners in the country realize that the methods of treating petroleum distillates have for the most part been handed down from one generation to another and that in many cases they are not satisfactory. They are of the opinion that work should be done to determine proper methods for treating distillates from the various types of crude, for at present a method for treating products from one type of crude may not be satisfactory for treating products of a certain other type. Also, the losses in treating are comparatively high, particularly in the case of the small refiners, who make use of open top agitators and as a result lose large amounts of the lighter fractions through evaporation.

Corrosion of Chromium Steels

It appears from a series of tests which the Bureau of Standards has carried out upon the corrosion of chromium steel that the behavior of the material when subjected to the acid test is not a sure criterion of its resistance to atmospheric corrosion.

Of all the alloys examined, a high nickel-chromium steel, invar, pure iron and medium carbon steel (very slowly cooled from a high temperature) were the most resistant to hydrochloric acid as measured by the loss of weight per unit area per day. High-chromium steels (for example, 13.70 per cent Cr, 0.29 per cent C) were found to be attacked by acid very much more readily. However, when the same specimens were subjected to a weathering test, consisting of a partial immersion in water and exposure to the air, the order of resistance was almost completely reversed. The high-chromium steels were the ones to withstand the treatment best, the low-chromium ones and the pure iron showing rust spots early in the test. The combination of both nickel and chromium appears to make the steel resistant to both acid and weather attack. In general, the steels which were quenched were found to resist corrosion better than the same material in the annealed state, but the differences found were much less than the differences resulting from composition changes, thus indicating that composition rather than treatment should receive primary consideration.

Y Alloy (Aluminum-Copper-Nickel-Magnesium)

A Light Aluminum Alloy Having the Strength of Soft Steel and Good Ductility—Easy to Cast and Roll —Retains Its Desirable Properties in Gas-Engine Parts Working at 250 Deg. C.—Immune From Season Cracking and Corrosion

AS NOTED recently in these columns,[1] a report to the Alloys Research Committee of the British Institution of Mechanical Engineers on "Some Alloys of Aluminum" has been published, a volume of nearly 300 pages. It represents work of 8 years, much of it done under war conditions, involving the whole resources of the National Physical Laboratory. Among its most important disclosures are methods of fabricating a so-called "Y alloy" (containing about 4 per cent Cu, 2 per cent Ni, 1½ per cent Mg, and remainder Al), which in cast and heat-treated form develops strengths as high as 47,000 lb. per sq.in., or when rolled and heat-treated, 54,500 lb. per sq.in. with elongation of 24 per cent in 2 in.

It has been very desirable to discover a light alloy which would retain its high heat conductivity and strength up to at least 200 deg. C. to be used for pistons in airplane or other high-duty gas engines. A comparison with an alloy heretofore much used for this purpose is given in Table I, and shows how well the demand was met.

Many compositions were investigated before the Y alloy was hit upon. It was known that Al:Zn:Cu alloys (ranged in order of importance) were weak at 200 deg. C. Al:Cu alloys containing more than 4 per cent Cu were stiff and hard to extrude, and their tensile strength at 200 deg. C. was not more than 16,000 lb. per sq.in. Additions of 1 per cent manganese seemed to produce an alloy conforming to the desired specifications, but it possessed serious casting difficulties. Small additions of Fe, Mo, W, Cr and V were found to make the casting extremely brittle and porous; intermetallic compounds of high melting point solidified as a skeleton, from which drained the mother metal. After the advantage of combined Ni and Mg when added to an Al:Cu alloy had been found, the relatively high elongation discovered at 350 deg. C. led to successful experiments in rolling and forging of a series of alloys from which the new Y alloy was selected, and which were also found excellent mixtures for casting. Small variations in composition (± 0.75 per cent) do not materially impair the important qualities of Y alloy.

Pouring and Heat-Treating Castings

Molds must properly provide risers of liquid metal to vent the considerable amount of gas evolved from Y alloy just before freezing, and to feed portions where "draws" or shrinkage cavities may be expected. (Total linear contraction is about 1.3 per cent.) Magnesium must be added just before pouring, in relatively large pieces of pure metal pushed below the liquid surface by a small perforated crucible, shown in Fig. 1. Experiments adding magnesium as an 80:20 Al:Mg alloy during melting produced unsound castings containing oxide inclusions. Nickel must be added to the mix as a "hardener," an Al:Ni alloy containing perhaps 20 per cent Ni. Y alloy castings seem to be unusually afflicted with minute holes ("pin-holes") appearing on machined surfaces, a defect which "need not be regarded as seriously deleterious to the casting."

Very important improvement in the physical properties of cast Y alloy may be had by heat-treatment, despite the negative effect of heat-treatment on cast duralumin. In order to approximate the strength of wrought material, chill castings (28,000 lb. per sq.in. ultimate) are given a 6-hour anneal at 530 deg. C., then quenched in boiling water and aged. This treatment, which is about 30 deg. higher than would be safe for duralumin, results in an ultimate strength of 47,000 lb. per sq.in. with 6.5 per cent elongation in 2 in. As shown by a comparison of Figs. 2 and 3, it has apparently caused the solution of some of the intergranular constituents, and a spheroidization of the remainder. Prolonged tempering of chill-cast Y alloy at 250 deg. C. reduces the strength to 22,000 lb. per sq.in. After quenching and aging, however, tempering at 250 deg. C. for 48 hours reduces the acquired strength no more than 10 per cent, and does not affect the elongation.

TABLE I—TESTS OF LIGHT ALLOYS AT HIGH TEMPERATURES

Temp., Deg. C.	88:12 Cu:Al Ultimate	88:12 Cu:Al Elongation	88:12 Cu:Al Conductivity	Y Alloy, Sand Cast Ultimate	Y Alloy, Sand Cast Elongation	Y Alloy, Sand Cast Conductivity	Y Alloy, Heat-Treated Rod Ultimate	Y Alloy, Heat-Treated Rod Elongation

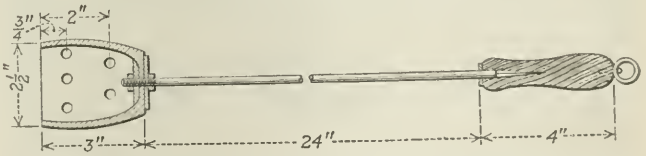

FIG. 1—PERFORATED CRUCIBLE FOR THE ADDITION OF MAGNESIUM TO LIGHT ALLOYS

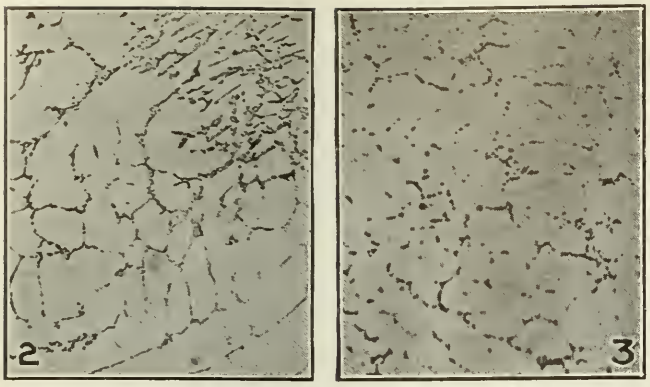
Reheating to 500 deg. C. and slow cooling completely softens the alloy, and it undergoes no subsequent aging effect.

Development of Y Alloy

The actual development of the wrought Y alloy is interesting, as an instance of successful synthesis. A preceding report to the Alloys Research Committee had indicated superior qualities in a 72:3:25 Al:Cu:Zn alloy. A series of low-copper Al-Zn alloys were therefore taken as a basis for experimentation, particular attention being given to the behavior during forging and rolling. It was soon found that 77:3:20 Al:Cu:

[1] "New Aluminum Alloys of High Strength," CHEM. & MET. ENG., vol. 26, No. 15, p. 689, April 12, 1922.



FIGS. 2 AND 3

Fig. 2—Y alloy as cast. Unetched. × 150.

Fig. 3—Alloy shown in Fig. 2 annealed 6 hours at 530 deg. C. and quenched in cold water. Unetched. × 150.

Zn (alloy "A") was the best of the lot, and complete information obtained on the proper way to roll rods, strip and very thin sheet. Magnesium (0.25 to 0.5 per cent) was next added, hoping that it would have the aging effect induced by its presence in duralumin. Manganese, a known hardener, was also introduced, and alloy "E" having the nominal composition: Cu 2.5 per cent, Zn 20.0, Mg 0.5, Mn 0.5, Fe not exceeding 0.2 per cent, Si not exceeding 0.2 per cent, was discovered, which was much stronger than anything of the sort hitherto known.

Both alloys "A" and "E," however, were deficient in strength at about 250 deg. C. It was thought that alloys containing Ni and Mg, which were not only strong but ductile at high temperatures, should be readily rolled and perhaps would retain their useful properties after working. It was immediately found that the addition of nickel, which was itself a hardener, markedly increased the *ductility* of alloys already so high in copper as to resist rolling. Comparison of tensile tests showed that 92½:4:2:1½ Al:Cu:Ni:Mg alloy was weakened only 10 per cent at 200 deg. C., and this mixture was then studied in detail as "Y" alloy.

Microstructure

Without entering into any detailed description of the microstructure, which indeed is not well understood as yet, it has been found that when Y alloy has been annealed and is in equilibrium, no compound corresponding to the $CuAl_2$ of duralumin is in existence. Nickel, even when present to less than 2 per cent, seems to form a ternary compound with aluminum and copper, as well as a compound $NiAl_3$. Thermal studies show the absence of critical points below 554 deg. C. The liquidus is also considerably above 540 deg. C. Consequently the microstructure and rationale of heat-treatment is entirely different from that of duralumin.

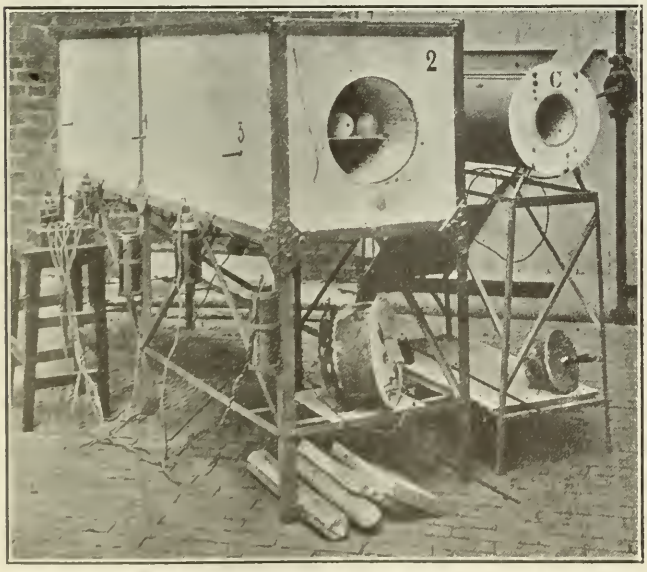


FIG. 4—ELECTRICALLY HEATED MUFFLE, 12-IN. DIAMETER, FOR HEATING LIGHT ALLOYS

Experimental Plant

Alloys were melted without charcoal or flux, about 25 lb. at a time, in covered salamander crucibles placed in an oil-burning pit, and poured into one 3-in. chill-cast round billet, 19 in. long; three chill-cast rods, 1 in. round x 7 in. long, and four shaped sand castings. Temperature was regulated by pyrometers, and no allowance was made for loss in melting.

Rolling was at first done in a commercial plant, but this was so unsatisfactory that a two-high 15-in. mill was erected at the National Physical Laboratory. It is driven by a 60-hp. direct-current motor, using storage batteries for source of power. By regulating the voltage applied, linear velocity of the rolls can be varied from 50 ft. to 200 ft. per minute. A removable attachment consisting of a double row of gas burners playing upon the slowly rotating rolls imparted to them the heat which they acquire during ordinary mill practice.

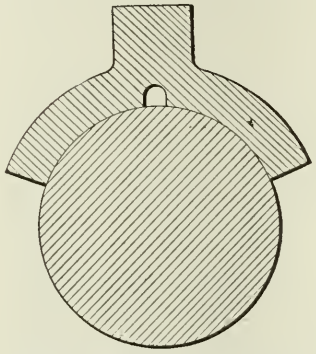

FIG. 5—ALUMINUM SADDLE FOR THERMOCOUPLE JUNCTION

Reheating and annealing was done in a large muffle shown in Fig. 4. It consists of a 12-in. steel pipe, 7 ft. long, covered outside with a layer of micanite and then wound with several sections of nichrome ribbon. The whole is bricked in with magnesia brick, and iron bound. Electrical heating coils are also provided for the ends, and a temperature gradient of ± 10 deg. C. is readily maintained at 400 deg. C., with a current consumption of 2 kw. This furnace has made over 1,000 heats in 5 years without any repairs or renewals whatever.

Temperature of the round billets was taken, without the necessity of drilling them for a thermocouple, by placing the aluminum saddle shown in Fig. 5 over them, and slipping the thermocouple junction in the groove between saddle and billet. When slabs were being heated, a spare slab, drilled for pyrometer, was charged in the furnace with the others.

Correct Forging and Rolling Practice

Difficulties with cracking during rolling, early encountered, were traced to surface defects in the cast billets. Preliminary forging seemed to close these surface imperfections somewhat, but billets free from surface defects were eventually made by pouring very slowly, in fact just raipdly enough to avoid cold shuts. For this purpose the molds (preheated to 100 deg. C.) were tilted to 45 deg., and the metal poured to match the solidification so that only a very shallow layer remained constantly liquid. Thus shrinkage cavities were

abolished. Surface and edge cracking occurring when rolling thin sheet in the experimental plant and later when much larger slabs were rolled in commercial practice was traced directly to surface defects in the slab—a slab which had been milled all over $\frac{1}{8}$ in. deep rolled perfectly. In the rolling mills various mechanical aids were tried, the most successful being the provision of a small V-shaped runner down the lower edge of the tilted mold. The tongue left on the slab is cut off before rolling starts.

Some of the alloys seemed to require a preliminary "breaking down" under a hammer. While chill-cast slabs of Y alloy $\frac{3}{4}$ in. thick will give no trouble in rolling[1] to rods, it is desirable to forge it before rolling into sheets. With $1\frac{1}{2}$-in. slabs, a reduction of 10 per cent should be given by forging in two heats at 240 deg. C. Then reheat the blanks to 480 deg. C. and roll to $\frac{3}{8}$-in. plate in five or six passes. Subsequent rolling can then be done at high speed and heavy draft.

Summary of Physical Properties

Table II gives a summary of the tensile properties of rolled Y alloy rods and sheets after heat-treatment. Table I also contains physical properties at elevated temperatures of a $\frac{3}{8}$-in. rolled rod, quenched from 480 deg. C. and aged 4 days. From this and a comparison of its strength in the rolled condition given in Table II

TABLE II—SUMMARY OF TENSILE TESTS ON ROLLED Y ALLOY

Material	Condition	Elastic Limit	Yield Point	Ultimate	Reduction of Area	Elongation in 2 In.
$\frac{1}{2}$-in. rod	Hot-rolled	.....	26,900	39,400	30.0	20.0
	Quenched from 530 deg. C. and aged	17,200	34,500	54,000	33.0	23.0
	Cold-rolled from $1\frac{1}{4}$-in., hot-rolled, quenched from 530 deg. C. and aged	17,200	34,000	54,100	34.0	25.0
$\frac{1}{2}$-in. rod	Cold-rolled from $\frac{3}{4}$-in., hot-rolled, quenched from 520 deg. C. and aged	.....	33,400	51,200	31.0	26.0
0.05-in. sheet	Hot-rolled; quenched from 480 deg. C., aged	.....	36,000	52,000	....	19.0
	Hot-rolled, quenched from 530 deg. C., aged	.....	38,500	58,200	..	19.0
	Cold-rolled; quenched from 530 deg. C., aged	22,000	46,500	60,200	...	17.0
0.018-in. sheet	Cold-rolled; quenched from 530 deg. C., aged	.....	47,000	62,800	..	17.0

it appears that prolonged heating to something over 200 deg. C. will remove the hardening effect. On the other hand, test-pieces held 100 hours at 150 deg. C. and tested at that temperature give the same tensile results as though the heating had endured but 30 minutes. Wohler fatigue tests on tubular test-pieces at 150 deg. C. (designed to show the expected endurance as connecting rods) gave a safe range of alternating stresses of $\pm$ 18,500 lb. per sq.in., wherein the metal may be expected to endure indefinitely, as compared to $\pm$ 23,000 lb. per sq.in. at room temperature. Table II also shows that an increased strength and unimpaired ductility may be had by quenching in water from 530 deg. C.—about 50 deg. higher than the proper temperature for duralumin. Even higher strengths may be had by cold-rolling $\frac{1}{4}$-in. plate, reducing thickness 10 per cent in each stage, and separating stages by a quenching from 480 deg. C. Sheet so prepared 0.05 in. thick, after quenching from 530 deg. C. in boiling water, shows an ultimate strength of 58,000 to 61,000 lb. per sq.in., and elongation of 16 to 18 per cent in 2 in.

[1]Rolls must be kept well lubricated to prevent them seizing and splitting the hot metal.

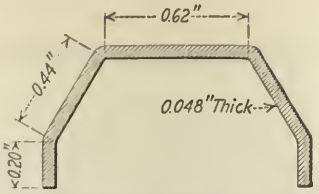

FIG. 6—ROLLED CHANNEL FOR COMPRESSION MEMBER

A channel, shown in Fig. 6, was made in a bending machine from heat-treated rolled strip, and cut into 6-in. lengths with squared ends. This was seated on ball centers, and tested in compression. A buckling stress of 30,600 lb. per sq.in. was developed by Y alloy, a figure 13 per cent higher than duralumin.

Corrosion Resistance

Y alloy is as light as any of the stronger aluminum alloys which have yet been produced, and is distinctly superior to most in the ease of manufacture. Its great superiority lies in a very remarkable resistance to corrosion, and its entire immunity from intercrystalline cracking under prolonged loading (season cracking). Without presenting details—since corrosion investigations are in the hands of the Institute of Metals committee—the eleventh alloys research report notes that both in the cast and rolled condition the Y alloy possesses considerably better powers of resisting corrosion, even when immersed in sea water, than the other high-strength aluminum alloys.

War Gases to Be Used for Extermination of Pests

Experiments on the use of poison gases for exterminating obnoxious birds, rodents and insects will be undertaken this fall, when the Biological Survey, in co-operation with the Chemical Warfare Service, will make a trial of the method on blackbirds in the Imperial Valley of California. In that region these birds are said to do at least $50,000 worth of damage to the milo crop each year. Because of their feeding habits it is impossible to destroy these birds with poisoned baits, but, as they roost on the reeds in the marshes, it is thought that they can be killed by a gas cloud at night when the wind is favorable. The blackbirds are migratory and return to the same places year after year. It is thought that a big killing in a certain locality will probably free it of the pests for many years. A few other birds in the blackbird-infested marshes will be killed at the same time, but the department believes that these local birds will soon reach their normal numbers again.

Arrangements also are being made by the Biological Survey with the Chemical Warfare Service for investigating the possibility of using poison gases on such burrowing rodents as rats, prairie dogs, ground squirrels and woodchucks. Tests on pocket gophers and ground squirrels by these two co-operating branches of the government in California show that chlorine may be used with good results if handled properly. The Chemical Warfare Service used phosgene on rats in Porto Rico with promising results. Some of these war gases will be compared with carbon bisulphide for the killing of woodchucks and other rodents in their burrows.

Entomologists of the department have already worked in co-operation with the War Department in testing various gases on insect pests of growing plants and those that infest stored grain, but it has not yet been found advisable to recommend anything to take the place of hydrocyanic-acid gas or carbon bisulphide.

New Developments in the American Glass Industry

Description of the Plant of the Kimble Glass Co., at Vineland, New Jersey—Development of Automatic Machinery for Making Glassware—Making Precision Scientific Apparatus in the United States—Development of a Force of Skilled Glassworkers

By G. L. MONTGOMERY

SHORTLY after the outbreak of the World War in 1914 it became extremely difficult to obtain certain articles for which the United States had been almost entirely dependent upon imports from Europe. As a direct result of this condition the more enterprising among our manufacturers began to take steps toward developing the manufacture of these articles in this country. One of the most important items which we were unable to get was technical glassware—that used by chemists, metallurgists, biologists, physicians, pharmacists and other scientists, and also by the United States Bureau of Standards. Small amounts of this product had been previously manufactured in this country; but production was not generally on a commercial scale, and the greater part of our demands had been filled by imports from the Central Powers.

One of the plants which undertook to stop this gap in our commercial structure was the Kimble Glass Co., of Vineland, N. J. Founded in 1907, this company had taken over a small, single-furnace plant of about 2½ tons daily capacity and 20,000 sq.ft. of floor area. In 1910 expansion had commenced and at the outbreak of the war the floor space had quadrupled and the plant was turning out a line comprising rods, tubes, homeopathic vials, test tubes, Babcock milk test bottles, and various other articles. At that time all processes both in the hot and cold metal plants were hand processes. The products were confined to such as could be made in quantity by hand and did not call for highly trained workers and technical control.

Developing the Manufacture of Glass by Automatic Machinery

In the manufacture of the Babcock milk test bottle this company had proved its ability to produce an accurately graduated article. In the emergency the government requested the company to go more extensively into the manufacture of graduated ware. The developing of a graduating department was immediately commenced. At the present time this department has over one hundred skilled operatives and turns out all types of precision graduated glassware, including apparatus complying with the specifications of the Bureau of Standards. Along with this development has also come the blowing and finishing of the complicated pieces of testing and surgical glassware formerly produced only in Austria and Germany. It was necessary to train the men for these new processes, as there were at the time no men available with sufficient skill. Those who had been engaged in the normal operation of the plant were trained along the new lines; but the shortage of labor prevalent during the period made it difficult to obtain workers to fill their places. From this has grown the manufacture in quantity on automatic machines of homeopathic vials, test tubes and other articles made from tubing.

The machines to perform these last-named operations were experimentally worked out in the plant, and have all been designed and patented, and are now manufactured there. The advantages following the use of these machines consist in larger output with fewer operatives, a uniform and high-quality product, and the provision of a staple quantity line in constant demand to back up the production of the varied line of special ware for which the demand may fluctuate.

Factors Governing Location in Vineland

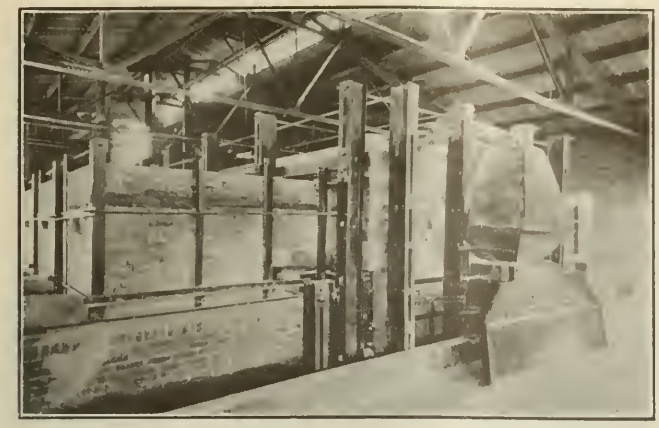
The town of Vineland is in the heart of the New Jersey glass sand district, and proximity to the source of the most important raw material and accessibility to the Eastern market and the ports of New York and Philadelphia were the factors determining the location at this point. About 900 tons of the glass sand are used annually. It is mined and washed at the company's mine, located near the plant, and is about 99.8 per cent SiO_2. The other materials used comprise yearly amounts of about 2,400 tons of gas coal, 2,800 tons of steam coal, 300 tons of soda ash, 150 tons of lime, and smaller quantities of coke, red lead, litharge, hydrofluoric acid, wax and various other commodities. These are brought in on the Central Railroad of New Jersey, which has two tracks leading into the plant. The Pennsylvania Railroad is also close by.

How the Plant Is Housed

The buildings of the plant are all one-story, reinforced concrete and brick buildings with wood deck roofs on steel trusses, except the structures containing the glass-blowing and machine departments and that housing the office, graduating and lamp departments. The glass-blowing and machine departments are one-story steel frame buildings with corrugated asbestos and brick veneer walls and asbestos roofs. The office, graduating and lamp departments are in a two-story mill type building. The total floor area of the plant is approximately 130,000 sq.ft., of which the raw material and batch building occupies 3,500 sq.ft., the hot metal plant about 30,000, the cold metal plant about 39,000, packing and warehouse about 43,000, power and heating 6,000, machine shop 3,600, laboratory 1,500 and office 1,500.

Handling the Raw Material

The raw materials for glass are brought to the plant by rail and delivered to the batch house. Due to the comparatively small quantity of these materials used, large storage space is not provided and the materials are stored in small piles on the floor. The batches are mixed here by hand and placed on large barrows, 1,000 lb. to the batch. It is essential that the batches be in accordance with an exact formula and the necessary care and attention can be had only by hand mixing.



TANK FURNACE OF 20 TONS DAILY CAPACITY

From the batch house the barrows are wheeled to either the glass factory or the tube machine building, which constitute the hot metal department.

The First Process in the Making of Scientific Glassware

The glass factory is the department in which the shapes used in the manufacture of scientific apparatus are blown. The equipment comprises a furnace for closed pots having a daily capacity of five 1,000-lb. pots, a "glory hole" and two hand-operated lehrs. Connected with the building, one on each side of the blowing floor, are two pot arch furnaces.

The glass to be annealed is placed in and removed from the lehrs by hand. This method is used in preference to mechanically operated lehrs because of the varied product, each different shape requiring a different amount of annealing. The pot furnaces are heated by direct coal fire underneath, being fed from the basement level by coal supplied from a trestle on the adjacent railroad siding. The lehrs are heated by oil, the burners being placed beneath the lehrs and fed from an oil supply in two nearby 10,000-gal. storage tanks. This means of heating the lehrs gives a better temperature control than is available by using coal or gas. Both the pot furnace and the lehrs are provided with indicating pyrometers in the glass factory and recording pyrometers in the plant laboratory, enabling both the factory foreman and the plant chemist to keep the temperatures under continual observation.

A tank furnace is at present being constructed in this building with a daily capacity of 5 tons for use in making resistance ware—i.e., ware which can be subjected to extreme variations in temperature without breakage. This tank is of the low arch type and will be heated by oil burned in pressure burners. The air necessary for combustion will be heated in a recuperator, situated on the same floor level and at the rear of the tank. A novel feature of this tank is that the charging of the batch and the extraction of the melt are both accomplished from the same side. This is possible due to the substitution of oil firing for the usual gas firing and the consequent elimination of flues on the sides of the tank. As a result it has been possible to place the tank in such a way as to conserve more floor space for blowing than is possible in the average installation.

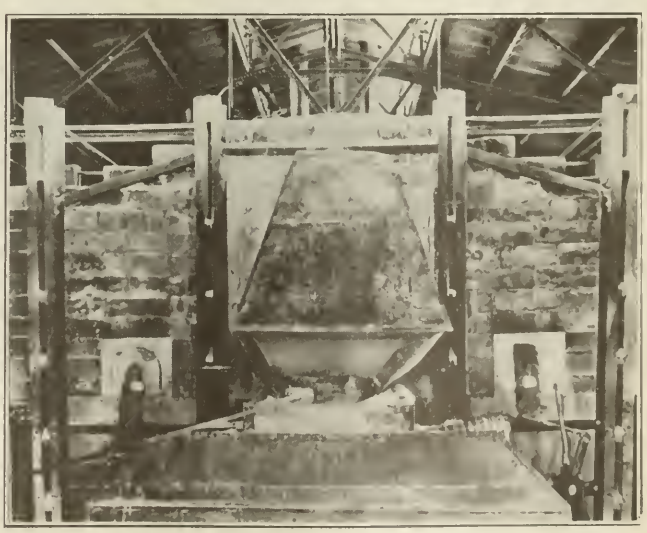
This department also contains two experimental furnaces for the development of new types of glass. One of these is a tank furnace called a day furnace and holding sufficient melt for a one-day run. The other is a pot furnace with a capacity of a single pot holding 500 lb. of batch. The glass pots used in the glass factory are purchased from outside the plant except in special cases of experimental development.

The manufacture of the complicated shapes used in making scientific apparatus requires blowers of more than ordinary skill. In training these blowers to meet the war emergency, the glass-blowing art of the United States has been brought level with that of Europe. If the art is allowed to prosper here, we need never again be dependent on others for articles of this type.

Drawing Tube and Rod Automatically

The tube machine department houses the equipment for drawing tube and rod automatically. The glass is melted in a continuous tank furnace of 20 tons daily capacity. This furnace is heated by producer gas supplied from the adjacent producer house under pressure and is of the regenerative type. It is provided with an indicating pyrometer. Placed immediately behind the refining end of this tank are four tube-drawing machines, fed with glass through separately heated feeding furnaces. These machines, which are a new and successful application of automatic machine principles to the glass industry, are manufactured by the Libbey Glass Manufacturing Co., of Toledo, Ohio. By means of them tubes or rods can be automatically drawn covering a wide range of diameters. A detailed description of the operation is given toward the close of this article.

The tube or rod is cut to lengths of 5 or 6 ft. in the tube machine and delivered by this machine to a storage rack. From this rack it is taken to the grading and sorting tables. Here the diameters of the rods are carefully measured and they are sorted into grades varying by $\frac{1}{32}$ in. These different grades are then placed in wooden boxes and taken either to the warehouse for shipment or stock, or to the cold metal department for manufacture into towel bars or similar articles. The tubes are carefully gaged inside and outside and are sorted into groups according to the inside diameter and the wall thickness. The drawing machines make about five different wall thicknesses for each different inside diameter of tube drawn. After sorting, the tubes are disposed of in the same manner as the rods, except that in the cold metal department they form the basis of the manufacture of a great many objects such as vials,



CHARGING END OF TANK FURNACE

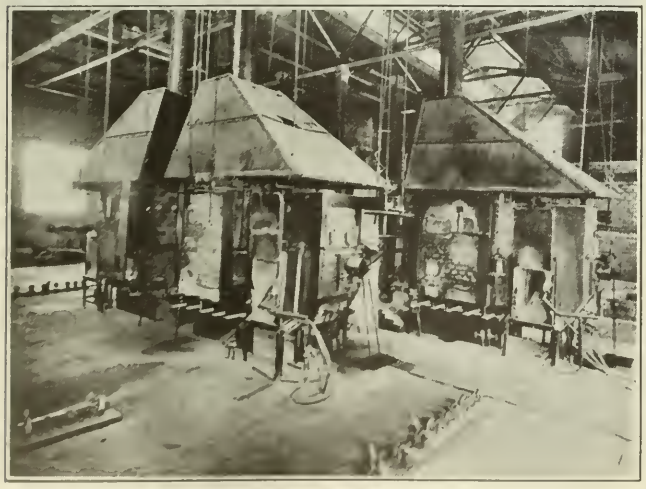
test-tubes, gage glasses, containers, oil cups and parts of scientific instruments.

Cutting and Sorting Glass Tubes

The cold metal plant consists of the cutting, sorting, lamp, machine, graduating, etching and finishing departments. All the products of the hot metal plant which are to be finished in this works are first brought to the cutting building. Here tubes and rods are cut to the required lengths and the remains of the gather and other superfluous glass are trimmed from the blown shapes. The trimming of shapes is done by hand. Rods and tubes are cut by circular glass saws, some hand fed and some machine fed.

From the cutting building the glass is taken to the sorting department on the ground floor of the building in which the lamp and graduating departments are located and immediately adjacent to the building housing the automatic vial machines. Here the stock for the lamp department is separated from that for the machine department and the sorted stock is stored for delivery to these departments as required.

An interesting machine has been developed for sorting the tubing for the machine department into the five different weights in which each diameter is made. A large number of pieces of tubing, each of the required diameter and cut to the required length, say 5 or 6 in., is placed in the hopper at the top of this machine. From this hopper the pieces are fed one by one onto a reciprocating and oscillating step bar having six steps and made of two similar steel strips spaced about 3 in. apart. The upper step has one groove for receiving the tubes and the five other steps each have two grooves. The reciprocations and oscillations are both accomplished in the same plane, at right angles to the axis of the piece fed from the hopper and having an axis inclined to the vertical about 45 deg. The amplitude of the oscillations from this axis is at a maximum about 3 in. either side, so that each groove describes a complete and rather flat ellipse for each cycle. At each upward stroke the reciprocating bar picks up in the groove on its top step a piece of tubing. As the bar starts on the downward trip, a pivoted and counterweighted piece, situated between the two parts of the bar, takes the piece of tubing off the top step into a groove cut in its outer end. Should the piece be of the lightest grade, it is not sufficiently heavy to tip this pivoted piece and on the return of the reciprocating bar it is picked up by the outer groove on the second step. All pieces heavier than the lightest grade tip the pivoted piece sufficiently to cause the tube to be picked up by the inner groove of the second step. Pieces in the outer groove are tripped off into a tray at the next oscillation of the bar, while those on the inner groove are picked up by the second pivoted and counterweighted piece. By a repetition of this series of movements the five different weights of tube are separated one from the other.



FEEDING FURNACES AND DRAWING MACHINE IDLERS

How the Scientific Ware Is Finished

All the stock which is to be worked up by hand is taken from the sorting area to the lamp department, on the second floor of the same building. Here the different articles are made by the usual combination of gas burners and hand tools. It is here that the complicated pieces of scientific ware are formed and it is worthy of note that this art has been developed by American workmen on a commercial scale, proving that the United States is able to compete in highly skilled hand trades, at least in her own markets, with the products of low-paid European labor.

A large portion of the product, on leaving the lamp department, is completed and is taken directly to the packing rooms. Other pieces which are for measuring purposes require graduation. The pieces on entering the graduating room are first calibrated and tested by men especially trained for the work, which requires delicate skill and extreme accuracy. These men place gage marks on the articles delimiting the portion of which the volumetric capacity has been determined. The pieces are then thoroughly covered with wax. They are then placed in the graduating machines and the required number of spaces is marked off between the determined points by making scratches through the wax to the glass.

The graduating machines are of both the hand-operated and motor-driven types and are similar to the dividing machines usually seen. However, in order to obtain the extreme accuracy required for scientific instruments, it has been necessary to build these machines

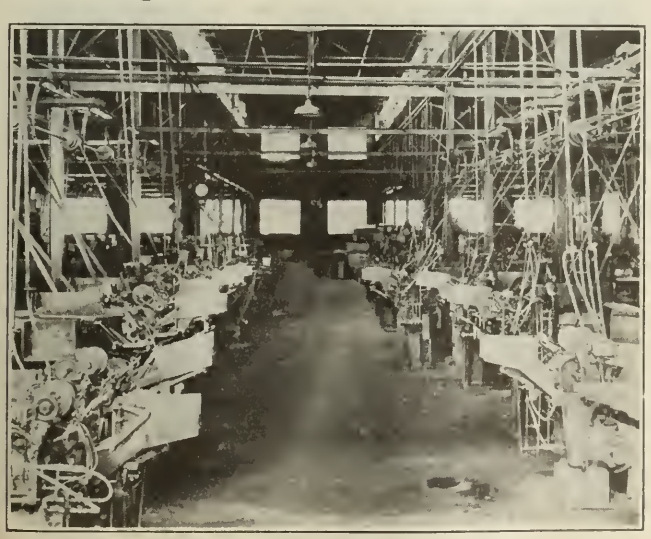
for the special service of this plant, as the ordinary machine such as is used in graduating thermometers is not of sufficient accuracy. At the present time, new machines are in course of construction, by means of which it is expected that the Bureau of Standards ware can be machine graduated. This ware is now graduated in the laboratory by hand by the most skillful workers employed in the plant.

Etching

For placing the figures, letters and other symbols on the ware to be etched, there are several machines adapted from the principle of the pantograph and very much like the machines used in engraving. The operator traces an enlarged outline of the desired character, and this outline is transmitted through the motion of the machine, in reduced size, to the desired place on the work. After the desired markings are made through the wax covering, the pieces are attached to trays by means of melted wax. These trays are then dipped into a bath of hydrofluoric acid, which etches the glass through the scratches. On removal from the acid bath, the glassware is placed in a machine similar to the ordinary dishwashing machine, where it is exposed to a live steam spray. The wax is melted off, and together with any acid which was on the piece, is washed down a drain to the floor below with the condensed steam. Here the wax is separated from the acid and water, is purified and is then returned to the graduating department to be used again. The etched pieces are dried. The markings are then filled with a substance to make them stand out clearly. In another part of this room such finishing operations as the grinding of stoppers, cock-valves, etc., placing electrodes, finishing and polishing towel bars are performed.

Automatic Manufacture of Vials and Test-Tubes

The tubing which is to worked up into quantity products such as test-tubes and vials is brought from the sorting room into the adjacent building which houses the automatic machines. These machines are a development of this plant and represent a distinct departure in the glass-working industry. The principle of operation is the same, no matter what the product turned out, and different products are obtained by different applications of heat, compressed air and mechanically operated forming tools.



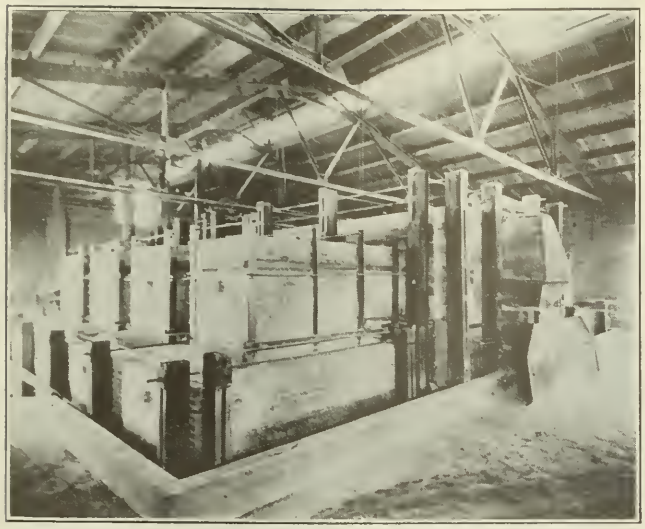
AUTOMATIC MACHINES FOR MAKING CORKAGE ON VIALS

AUTOMATIC MACHINES FOR MAKING BUTTS ON VIALS

The machine used for making test-tubes is a good example of the methods followed. Here the stock is fed from a hopper, one piece at a time, down an incline to a point where it is taken up between two sets of revolving rollers. These rollers are mounted in pairs on shafts parallel to each other and to the axis of the piece of tubing. The tubing lies in the groove formed between the two sets of rollers. The rotation of the rollers causes it to revolve, and at the same time one end is subjected to the heat from several gas burners. When it is sufficiently heated, the gas burners automatically move out of the way and a forming tool or die is brought into play which forms the flange of the heated end of the tube. This flange being formed, the piece is then ejected from the first set of rollers and moved along a set of conveying rolls to another set of rollers similar to the first. Here the flange is formed on the other end of the tube. The piece then moves to a third set of rollers. Here the heat is applied to the middle portion in such a manner that when the tube is drawn slightly apart by a pressure exerted on the two flanges, it is separated into two pieces, each piece having a closed end. While these closed ends are sufficiently hot to be worked, the gas burners are withdrawn and a forming tool is brought into contact with each of them. At the same time compressed air is introduced into the outer ends of the tubes and the hot glass is caused to form an even spherical butt for the tube, filling out the cup in the forming tool, the glass being evenly distributed throughout the butt. This completes the tube, and it is released and conveyed into a hopper at the end of the machine for finished pieces. The cycle of operations is repeated for every tube made by the machine, and as a result the product is absolutely uniform. Also, due to the fact that in forming the butt the air pressure is under absolute control and the glass is caused to spread evenly and is more homogeneous than in the hand-made product, a test-tube is made of much greater strength than by the older method. At the same time it looks better and can be sold at as low a price.

The Packing, Shipping and Warehouse Departments

After the glass has been through the final manufacturing process it is taken to the packing rooms to be placed in the appropriate containers. These containers are made on the ground from semi-finished stock pur-



TANK FURNACE FOR AUTOMATIC DRAWING MACHINE

chased outside, and are of both paper and wood. The department is commodious and well arranged, but the methods used are the usual methods of hand packing and present no feature worthy of special notice.

From the packing rooms the filled containers are either shipped by truck or rail, or taken to the warehouses and placed in stock. These warehouses are conveniently placed on either side of the main track leading out of the plant. The stock is handled into and out of the packing rooms and warehouses on storage battery trucks or on hand trucks as may be convenient.

There is a very complete machine shop in the plant, used for making repairs to the existing equipment and for the manufacture of the automatic machinery which was described above. This department is located in a separate building, placed directly adjacent to the machine department, where most of the work for the shop originates.

Power, Heat and Producer Gas

Electric power is purchased from the Vineland Electric Co., about 15,000 kw-hr. being the monthly load for all purposes. High-pressure steam for the compressors, the producer and for process use is supplied from a 125-hp. water tube boiler. Low-pressure steam for heating purposes is supplied from four small heating boilers, placed in a separate building located centrally to the buildings where this heat is needed. The producer, supplying gas for the tube-machine tank furnace and for process uses in the various departments, is a standard Chapman producer. The amount of gas produced is about 1,000,000 cu.ft. per month.

Laboratory

The laboratory consists of two divisions, physical and chemical. The physical laboratory tests the products after annealing for strain and for strength and makes other similar tests as needed. For the present the Bureau of Standards ware is calibrated and marked here, but this work will be transferred to the graduating room when the graduating machines mentioned above are in operation. The chemical laboratory does experimental work in the development of new kinds of glass, makes tests for process control, and tests the materials used in the plant. These tests do not include the specification tests on raw materials, which are periodically made in an outside laboratory by a consulting chemist.

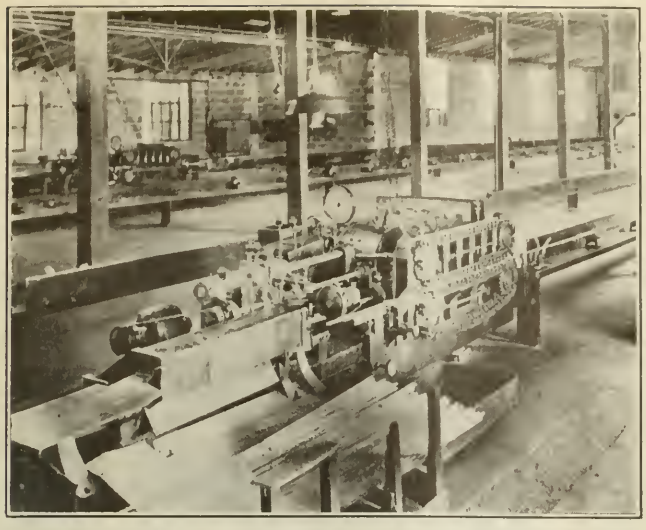
Machinery for Automatically Drawing Tubing

The machine used in the automatic manufacture of tubes and rods is not a new development peculiar to this plant; but as its use is by no means general, a description of it should prove of interest. The molten glass is fed onto a slowly rotating arbor which is situated in a heating furnace. Four of these heating furnaces are placed at the refining end of a tank furnace opposite the feeder openings. The feeder opening is connected to the heater furnace by a separately heated trough, so located that the glass flowing through the trough flows onto the arbor and forms a complete film over it. The arbor is mounted with its delivery end somewhat lower than the other end and in the start of the process a knob or lump forms on this end as the glass flows over the arbor. The operators attach a bar to this knob and walk rapidly away from the arbor. At the same time a current of compressed air is introduced within the glass from a hole in the delivery end of the arbor. In this manner the propagation of the tube is commenced.

As soon as the tube has been drawn out by hand to a suitable diameter, the operators place it in the machine and the drawing is continued as long as the supply of liquid glass continues to flow over the arbor.

Immediately following the rotating arbor and on a line which is a continuation of the horizontal projection of the axis of the arbor is a series of grooved idler wheels. These wheels are placed near the floor of the building and at a somewhat lower level than the delivery end of the arbor. In the machines in use at the Kimble plant the row of idlers is about 120 ft. long. The tube, which is placed in the grooves of these idlers and held there by means of asbestos guides, passes over them into the pulling machine. This machine supplies the motive power for the drawing after the operators place the tube in it. The pulling element consists of two endless chain belts, one above the other, in line with the tube as it leaves the idlers. These belts are made of links from 3 to 4 in. in length and carrying at the outside surface of the chain over each joint a pivoted, asbestos-covered plate which serves to grip the tube. The lower chain runs over a rigid guide, and the lower strand of the upper chain runs through an ad-

HEATING FURNACES, ARBOR AND INTAKE OF DRAWING MACHINE, SHOWING TUBE ON IDLERS



PULLING MACHINE, CUT-OFF AND STORAGE RACK

justable guide which holds the chain on the tube by spring pressure and can be moved up or down to accommodate different sizes of tubing. The pair of sprockets driving the upper chain are also provided with a vertical adjustment. This pulling machine is driven by a motor.

How the Automatically Drawn Tube Is Cut in Useful Lengths

On the other side of the pulling machine from the train of idlers is located the cut-off. This consists of a circular glass saw with its axis of rotation parallel to the travel of the tube, arranged to be moved back and forth along the path of the tube and also capable of being moved against and away from the tube. The machine can be set to cut the tube in various lengths as desired. When a sufficient length of the tubing projects from the pulling machine the saw is brought forward horizontally so that its swiftly rotating edge is against the tube. At the same time it is caused to travel with the tube and at the same speed. When a notch is completed the saw is withdrawn horizontally and makes a quick return to its first position in time to pick up the next length of tube as it issues from the pulling machine.

The piece of tubing which was notched by the saw is broken off by the movement of a slotted disk forming one end of a wheel made up of a series of long sheet metal vanes. It falls between two of the vanes and by its weight causes the wheel to revolve. As the vane inclines the piece of tubing rolls off into the storage rack and the wheel comes into position to receive the next piece broken off. All the motions described above may be set to suit the particular work to be done and are then accomplished automatically until the setting of the machine is changed. To make rod instead of tube the only difference is that a solid arbor is used at the head of the machine, no current of air being needed.

Conclusion

In conclusion, the writer believes that the plant described above is noteworthy for three reasons: First, for the development of the manufacture of glass by automatic machinery; second, for the manufacture of precision scientific glassware in the United States on a commercial scale, and last, for the training of a force of skilled glass workers capable of blowing and working up the most complicated articles.

Recent Developments in the Sulphur Industry

In connection with the recent announcement by the Freeport Sulphur Co. that it had reached an agreement with the Texas Co. by which the Freeport obtains the sulphur lease at Hoskins Mound, the sulphur deposit owned by the Texas Co., attention is called to the growth of the industry in this country by an article in *Financial America* of March 25, 1922. It is believed in trade circles that the arrangement just concluded will have a stabilizing influence over the industry, particularly as it eliminates the possibility of a fourth sulphur company in this country. The Texas Co., it is stated, has been endeavoring for a couple of years to enter upon such an arrangement, and other companies besides the Freeport have also made proposals.

The total sulphur reserves of the Texas Gulf Sulphur Corporation are estimated at over 15,000,000 tons, notwithstanding that in excess of 2,000,000 tons of commercial sulphur already has been taken out of its mines. The Union companies' sulphur reserves are estimated as in the neighborhood of 4,000,000 tons, those of the Texas Co. in the Hoskins Mound at between 5,000,000 and 6,000,000 tons and those of the Freeport Sulphur Co. at around 2,000,000 tons. The Freeport Sulphur Co. has not been operating its mines since April 1, 1921. The amount of sulphur that it had mined up to that time was slightly in excess of 2,000,000 tons, of which there was then above ground 343,609 tons.

Engineers who have been employed to ascertain the facts relative to the extent of the deposits in the Hoskins Mound say that it will probably require 2 or more years completely to develop and equip it and until the first two or three hundred thousand tons have been actually placed on the surface it will be impossible to predict whether the quality of the sulphur will be such as to meet the trade requirements.

Would Increase Chilean Iodine Production

Recently objections have been voiced in Chile against the monopoly which has been exercised for 34 years in the control of the iodine trade, according to the statement of Commercial Attaché C. G. McQueen, of Santiago. Claims are made that the possibility of modern application of iodine to industrial processes would warrant a thorough extraction of the material and the lowering of prices to a commercial scale. The present arrangement requires that all iodine contained in the ore whose extraction is not permitted by the quota assigned the plant must be thrown away and lost entirely. Statements are made that in place of the quantity of iodine now extracted and exported (something over 500 tons annually) from 10,000 to 14,000 tons could be produced if all the iodine contents of the treated ore were recovered.

The advocates of free elaboration and sale of iodine base their arguments on the three following grounds: The greater revenue derived by the government from a greatly increased exportation, even at a lower rate of duty; the possibility of using a free production of iodine and its sale at a fair profit as a means of adding to the revenues of individual producers and lowering the cost of the nitrate of soda to a point which will aid in recovering the ground recently lost to artificial nitrogenous fertilizers; and the liberation of iodine from exclusive use in pharmacy on the presumption that a lower price would encourage its use for other purposes not practiced because of prohibitive cost.

The Piette Coke Oven

By Hector Prud'homme

Vice-President and General Manager,
Belgian American Coke Ovens Corporation

THE Piette type of coke oven was built experimentally for the first time in the United States by the Franco-Belgian Coke Oven Corporation of Brussels, Belgium, at the Carondelet coke-oven station of the Laclede Gas Light Co., St. Louis, Mo. This construction of eight ovens was made for the purpose of a demonstration preliminary to the organization by the Franco-Belgian Coke Oven Corporation of the Belgian American Coke Ovens Corporation. Very minute tests have been conducted on these ovens by the Laclede Gas Light Co. during 30 consecutive days and the ovens have been in regular operation for over 14 months. The Franco-Belgian Coke Oven Corporation has more than 1,500 modern ovens in commercial operation in several countries in Europe. However, the construction in St. Louis, which was made exclusively at the expense of the Franco-Belgian Coke Oven Corporation, was experimental and, therefore, limited to eight ovens.

The efficiency of the new ovens has drawn the attention of experts in metallurgy and gas works of many states of the country. They are regarded by their designer as the coronation of many years of effort toward improving processes for carbonizing coal and the recovery of byproducts. Beyond any doubt these ovens will materially assist toward a more economical utilization of the natural resources of the country.

General Character of the Oven

The Piette oven is of the horizontal type, with vertical flues, transverse regenerators and reversing arrangement. The regenerator chambers run the whole

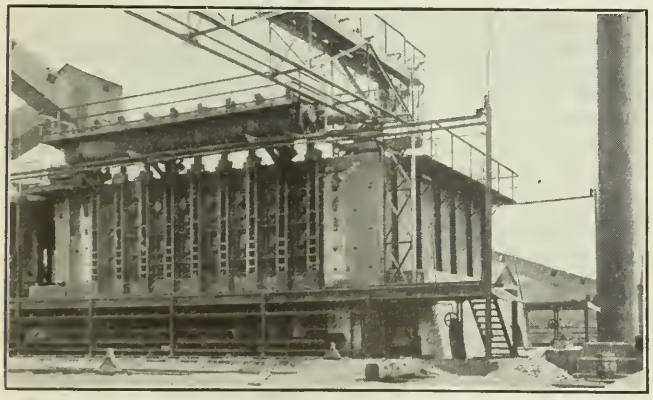


FIG. 1. GENERAL VIEW OF OVENS

length of the battery at right angles to the heating walls and oven chambers. This intercrossing of the walls is designed to give maximum of stability to the whole structure. Arrangements are provided for expansion when the ovens are heated, so that no fractures will occur to interfere with the proper working of the ovens.

Although arranged in longitudinal chambers, the regenerators are actually of the transverse type, and the products of combustion cross through the checkerwork in a direction parallel to the center line of the oven and travel longitudinally only after arriving in the free space of the secondary chamber. The total resistance is thus lowered to 5 or 6 mm. of water-gage, instead of the 30 mm. usual in longitudinal regenerators. In this way the pressures in the oven chambers and heating flues are more nearly equalized, and a maximum of gas-tightness and a maximum recovery of byproducts is assured.

While not essential, the use of a fan for the air supply will tend more nearly to equalize the pressures between the oven chamber and the heating wall, and

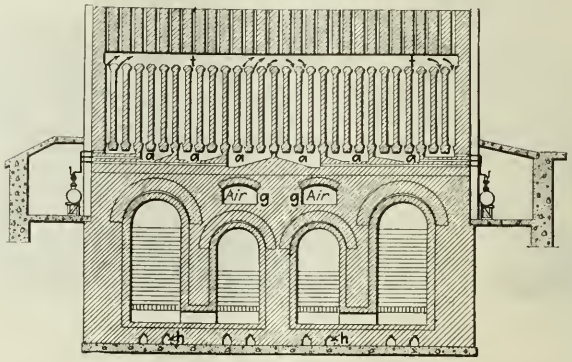

FIG. 2. SECTION THROUGH HEATING FLUES

prevent the passage of gases in either direction as the ovens become older.

Regulation of Gas and Air to Heating Flues

The center-line of the battery divides the heating wall into two symmetrical parts, reversals being made from one half to the other. The space between the sole flues of each half is divided into four chambers *a* (Fig. 2), each fed by an individual gas supply pipe provided with its regulating cock and distributing the gas to four vertical flues. Independent of these cocks, there is also a control cock common to each half-wall. The air for each half is regulated by a damper *r* (Fig. 3), at the inlet to the sole flue *s* (Fig. 3) of the oven adjoining. The area of the air-nozzle for each burner is determined with great care.

This oven may also be constructed, if desired, by arranging the reversal from one group of two or three flues to the next group of two or three, by slightly modifying the method of coupling the vertical flues with the sole flues, and using suitable reversing cocks.

The air for combustion is drawn through flues *g* (Figs. 2 and 3) to absorb the heat radiated downward from the sole flue, as well as through air ducts *h*, to take up the heat radiated downward from the regenerators. Thus preheated, the air arrives at the reversing valve and is there directed alternately into one or other of the secondary regenerators.

The several means of control, to which there is easy

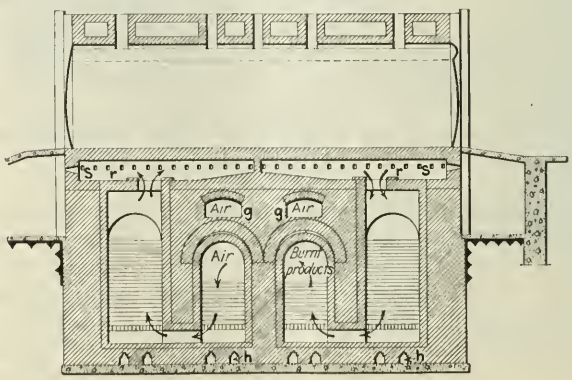

FIG. 3. SECTION THROUGH OVEN CHAMBER

access, enable great regularity of heating to be obtained, at a high, even temperature. The reversal of the draft and the operating of the burner valves are carried out by the working of a single lever.

To make the operation of the oven easy and certain, sight-holes for the examination of every part are provided, one for each vertical heating flue on top of the ovens, one in each half of the sole flue *s;* one in each horizontal flue *t* (Fig. 2) in the heating wall; one in each regenerator chamber. Those who are superintending and controlling the ovens have thus every facility for even heating of the battery at any speed.

Operating Test of Experimental Battery

The dimensions of the eight ovens installed at St. Louis are as follows:

Height of oven chamber	9 ft. 10⅝ in.
Length between doors	37 ft.
Average width	19¾ in.

The ovens were maintained in regular operating condition for the production of coke of good quality and for maximum yield of available gas of high calorific value. The 30-day test was begun after the ovens had been operated for 3 months. The figures in Table I show in more detail the results obtained.

The mixture of coal charged in these ovens during the 30 days of tests was as follows: 65 per cent of high volatile coal (Elkhorn from the Consolidation Coal Co.) and 35 per cent of low volatile coal (Pocahontas from the Cleveland-Western Coal Co. of West Virginia). The average analysis of this mixture was:

	Per Cent
Moisture	4.43
Volatile	29.06
Fixed carbon	61.37
Ash	5.14
	100.00

The yield of coke and the researches as to its nature were made by weighing daily the load of one oven, which was then screened and the samples submitted to laboratory tests. The results are given in Table I. The screening was done on an inclined 2½-in. roller grizzly screen.

These figures show that the yield in available B.t.u. would be, after deducting the B.t.u. needed for heating the ovens, 60.9 per cent of the total quantity of B.t.u. produced. This already very satisfactory proportion does not, however, represent the real power of this system of ovens.

A small number of ovens can, of course, not give the same yields as a bigger battery, of say fifty or sixty or more ovens of the same type. In the case of a big battery the gas used for the heating of an end-wall, which was found to be more than half the amount used on one oven wall for intermediate flues, is distributed over a larger number of ovens and as a matter of course over a larger quantity of the coal distilled. If the heat used in one end-wall is distributed over a battery of fifty to sixty ovens, the average number in a modern battery, the reduction in B.t.u. consumed in comparison with a battery of eight ovens is about 6 per cent. Taking this into account, the calorific balance sheet of the Piette ovens working under the conditions described above at St. Louis is as follows:

	Per Cent
B.t.u. produced, 3,301.7 per lb. of coal	100
B.t.u. in the surplus gas, 2,088.4	63.25
B.t.u. consumed in the heating gas, 1,213.3	36.75

TABLE I—RESULTS OF TESTS

A.	Ovens and coal:	
	Number of ovens charged and pushed	282
	Average coking time	20 hr. 18 min.
	Average load per oven	26,770 lb.
	Total quantity of coal charged in 30 days	7,549,400 lb.
	Average quantity of coal charged in 24 hr. per oven	31,455 lb.
	Average temperature of the smoke at the outlet of the heat regenerators corresponding to 3 8 per cent oxygen or an excess of 25 per cent of air	624 deg. F.
B.	Coke:	
	Total yield of dry coke calculated on coal as charged, per cent	69.19
	Proportion of foundry coke in total coke	38.15
	Proportion of other grades of coke	61.85
	Average analysis of the total coke obtained, per cent:	
	Moisture	1 94
	Ash	6 77
	Fixed carbon	90 33
	Volatile matter	0 96
	Specific gravity:	
	Apparent	0 973
	Real	1 906
	Shatter test	55 57
	Porosity:	Per Cent
	Coke substance by volume	51 03
	Air spaces by volume	48.97
	Total quantity of coke produced in 24 hours in one oven, lb.	21,764
C.	Heating gas:	
	Volume of gas burnt during the 30 days in cu.ft. at 30 in. pressure and 60 deg. F.	20,332,000
	Volume of gas burnt per lb. of coal charged	2,695
	Heating value of this gas (B.t.u. per cu.ft.)	479.3
	Consumption in B.t.u. per lb. of coal charged	1,290.7
D.	Gas produced and B.t.u. available:	
	Total volume of gas produced during the 30 days at 30 in. and 60 deg. F., cu.ft.	44,159,000
	Volume of gas produced per lb. of coal charged in cu.ft.	5.849
	Average calorific value of this gas (B.t.u. per cu.ft.)	564.5
	Total quantity of B.t.u. available per lb. of coal charged (non-debenzolized gas)	3,301.7
	B.t.u. (surplus) available per lb. of coal treated	2,011.0

Average analysis of the gas produced:

	Per Cent		Per Cent
CO_2	1.7	CO	6.1
C_nH_m	3.4	CH_4	29.8
O_2	0.4	N_2	6.8
H_2	51.8		

Average specific gravity at 30 in. mercury and 60 deg. F. 0.39. Yields of byproducts per ton (2,000 lb.) of coal carbonized:

Ammonia (NH_3), lb.	5.63
Tar, dry, gal.	7.01
Benzene (product distilling below 200 deg. C.), gal.	3.42

This consumption is the smallest yet realized in the United States considering the conditions imposed by the tests.

Advantages Claimed for the Piette Oven

The most important characteristics of the Piette oven are:

1. The carbonization chamber and the whole structure are perfectly tight, which has been shown during the St. Louis tests. This, together with a perfect regulation of the heating and the excellent heat regeneration qualities, has permitted the extraction from the coal of the maximum of byproducts.

2. Short-circuits in wall flues have been done away with through the reunion, in two continuous series, of the upward-flame and downward-flame flues. This arrangement acts favorably in the exchanges of heat with the consequence that the work of the regenerators is facilitated.

3. The distribution of the gas in each oven wall by several compartments fed by individual tuyeres, each supplying the gas to three or four flues, permits the regulation of the quantity of gas admitted at every point of the oven in such a manner that it takes into account the effects of the taper and the cooling from outside.

4. The use of fixed regulating sections for the entrance of the air under the soles and the outlet of the burnt gases through the top of the vertical flues, which sections are calculated and confirmed by practice, makes the use of sliding bricks unnecessary. The placing of such sliding bricks is always very difficult for the heater who has charge of them, and it has been found many times that these small bricks remain stuck after some time, which fact prevents a first-class regulation of the

batteries where such device is employed. The unremovable regulation sections of the Piette ovens are superior, because they need no adjustment of any kind and are not exposed to the consequences of the whim or indifference of the heaters. More uniform heating of the oven walls is obtained, as was shown under every kind of running conditions at the new battery at the Laclede Gas Light plant.

5. The fact that the longitudinal regenerators work transversely, and thus establish an automatic regulation of the temperature of the combustion air, assists materially in the equalization of the heating of the several ovens of the battery, an advantage which does not exist in the ovens having individual transverse regenerators. The uniformity of the temperature of all the ovens of the battery which was noted daily at the St. Louis plant was a feature of the tests.

6. The two transversal-conjugated-regeneration galleries on each side of the center line of the battery allow (through a convenient regulation of the sections of the communicating openings existing between the primary gallery and the secondary gallery) for compensating the effect of the drop of pressure in the outlet gallery for the combustion products and for establishing correspondingly a uniform working of the depression for all the ovens. These sections are so calculated and the quantity of checkerwork placed in the secondary gallery is such that they are perfectly sized for the products going out and in the following period for the air coming in through them.

7. The aërating galleries *g* between the soles and the secondary regenerators as well as the galleries *h* under the heat regenerators assure a convenient cooling of the combustion products and a saving of radiating heat through a reduction of this radiation. These advantages were clearly shown during the tests referred to in this article, the air being heated to 200-280 deg. F. before entering the regenerators proper.

8. The stability of the ovens is remarkable. The regenerators are longitudinal to the center line of the battery and therefore perpendicular to the center line of the oven-walls and the arches of the ovens. This intersection of the walls and the ovens makes for a maximum solidity of the mass of the battery. Then the expansion of the linings and of the arches of the regenerators, as well as of the flues connecting the primary regeneration galleries with the sub-sole flues, is rendered completely independent of the general sustaining mass of the battery. The result thereof is that the refractory material which constitutes the sole-oven walls and the ovens are built on an absolutely rigid monolithic block which cannot be deformed. Such a disposition is remarkably advantageous with the silica bricks so extensively used in the United States which expand so much. The system in which the oven-walls proper of the oven are placed on regenerator walls, of which they are a part, can evidently not realize a similar tightness. The unequal temperatures which are found from the foot of the regenerator walls to the top of the oven-walls justify unequal expansions from level to level which cannot but cause cracks.

9. The ovens are easily operated and watched. As explained above, sight-holes are placed all along the passages of the flames and the gases, which are thus made accessible everywhere. The sight-holes placed at the end of the primary regenerators permit an inspection of the top of the checkerwork for the whole length of the battery. The progress of the heating is easily followed by heat coloration and general aspect of the ensemble. This inspection shows whether any oven-wall is being insufficiently heated, due, for instance, to an accidental obstruction of a cock or of a gaspipe.

To these advantages let us add the very special care taken by the builder of this type of oven to avoid anything that may complicate the construction or the operation. The whole oven gives an impression of solidity and simplicity.

The Franco-Belgian Coke Oven Corporation builds other types of ovens also—ovens without heat regeneration, ovens heated from the top of the oven-walls adapted to special kinds of coals, and finally ovens heated either by producer gas or blast-furnace gas. In this article, however, only the type of oven installed at St. Louis is described.

Synopsis of Recent Chemical & Metallurgical Literature

The Strength of Mechanically Welded Pressure Containers.—In a paper published in *Mechanical Engineering*, April, 1922, and to be read at the spring meeting of the A. S. M. E., Prof. R. J. Roark gives the results of an investigation made for the Vilter Manufacturing Co., of Milwaukee, to determine the strength and uniformity of pressure containers with electrically welded head joints. The containers were made of lap-welded pipe and were provided with spherical flanged heads. Their dimensions

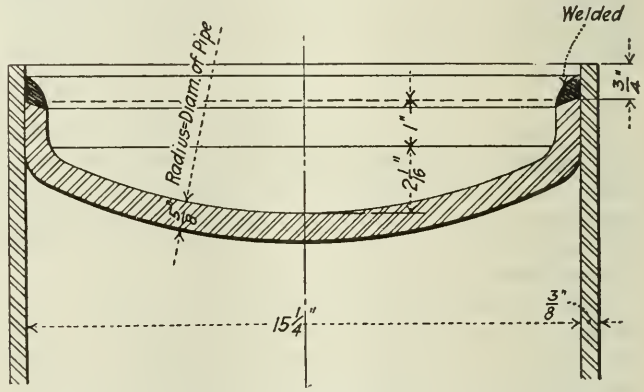

FIG. 1—SHAPE AND DIMENSIONS OF SPECIMEN CONTAINER

are given in Fig. 1. The average physical and chemical properties of the steel used were as follows: Yield point, 38,000; ultimate, 64,000; elongation, 27 per cent; carbon, 0.17 per cent; manganese, 0.44 per cent; phosphorus, 0.010 per cent; sulphur, 0.027 per cent.

It was proposed to determine the absolute strength of such containers by pressure tests on representative samples and to establish a comparison with vessels of like form and dimensions, but with gas welded and riveted heads. The tests were in three separate sets—namely, tests on containers, tests on specimens cut from containers and tests on special specimens of welded metal.

The tests on containers consisted in subjecting the specimen to an internal hydraulic pressure which was gradually increased until rupture resulted or such rapid leakage developed as to make further increase of pressure impracticable. The results of these tests are given in Table I. The values given for maximum shearing stress and maximum tensile stress in Table I do not represent the strength of the material in shear and tension, but simply the approximate shear and tensile stress produced in the welded joint

TABLE I.—RESULTS OF PRESSURE TEST ON CONTAINERS

Specimen Number	Description of Specimen	Pressure in Lb. Per Sq.In. at First Observed Leakage	Pressure in Lb. Per Sq.In. at Disking of Heads	Pressure in Lb. Per Sq.In. at Maximum	Method of Failure	Stresses on Head Joint at Maximum Pressure: Longitudinal shear lb. per linear inch of joint	Radial tension lb. per linear inch of joint	Bending moment inch-lb. per linear inch of joint	Max. resultant shearing stress lb. per sq.in.	Max. resultant tension stress lb. per sq.in.	Remarks
1	Standard commercial container with electrically welded heads, size 16 in. x 10 ft.	1,925 (1,820)		2,150 (2,040)	Longitudinal crack, started at nipple	7,770	870	1,780	9,800	15,000	
2	Standard type container with gas welded heads, size 16 in. x 10 ft.		2,150 (2,040)	2,200 (2,090)	Head forced off	7,960	900	1,820	10,500	16,000	Fracture on section *B-B*
3	Standard type container with riveted heads, size 16 in. x 10 ft.	1,200 (1,120)		2,100 (2,000)	Excessive leakage						
4	Container with gas welded heads and gas welded longitudinal butt joints, size 16 in. x 10 ft. (weld by Le Quelle)			1,600 (1,540)	Split along long. butt weld						
5	Container with gas welded heads and gas welded longitudinal butt joints, size 16 in. x 10 ft. (weld by Vilter)			1,300 (1,240)	Split along long. butt weld						
6	Container with electrically welded heads and electrically welded longitudinal butt joints, size 16 in. x 10 ft.			1,400 (1,340)	Split along long. butt weld						
	Reinforced container with electrically welded heads (3 concentric shells, concrete filled), size 10 in., 12 in., 14 in. x 3 ft. 2 in.		4,500 4,800	(4,800) (4,680)	Head forced off	11,860			18,000		Fracture on sections *B-B* and *C-C*
8	Reinforced container with gas welded heads (3 concentric shells, concrete filled) size 10 in., 12 in., 14 in. x 3 ft. 2 in.	4,350 (4,230)	4,100 (3,980)	4,350 (4,230)	Excessive leakage at weld joints	10,720					
9	Special container with one electrically welded; one head riveted, size 16 in. x 2 ft.	1,750 (1,670)		2,500 (2,390)	Split along lap weld	9,100			11,600	17,600	

by a pressure which caused failure at some other point. In making tests on specimens cut from containers, tests were made for shear and tension. The form and part of containers from which the specimens were cut are shown in Fig. 2. Specimens of Type A were tested in tension, the ends being held in wedge grips. The breaking load, eccentricity at rupture and manner of failure were noted. From these data the computed ultimate stresses on the weld were determined. Specimens of Type B were tested in shear.

The tests on special specimens of welded metal were made with the purpose of determining the actual tensile and shearing strength of the welds.

In conclusion, the author states as follows:

1. *Weak Points in Containers.*—None of the welded containers of standard design failed primarily at the welded head joint. The nature of the fracture shows that the weak points in the containers were, first, the lap weld in

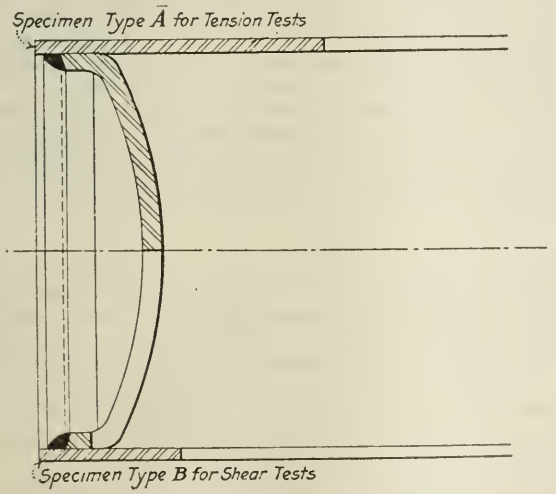

FIG. 2—SHAPE AND LOCATION OF SPECIMENS SUBJECTED TO SHEAR AND TENSILE TESTS

the pipe forming the shell, where failure occurred due to circumferential tension, and, second, the body of the shell at its junction with the head flange, where failure occurred due to the combination of longitudinal tension and bending. It appears that leakage is likely to occur first where couplings and nipples are welded in. This is due to the fact that the metal of the shell stretches and pulls away from the nipple, which does not have a corresponding strain induced in it by internal pressure.

2. *Strength of Electric Welds.* The average tensile strength of electrically welded joints was found to be 28,500 lb. per sq.in. From tests on specimens cut from containers, the average shearing strength of electrically welded joints was found to be 25,500 lb. per sq.in. The mean variation from the average tensile strength per linear inch of weld was found to be 2 per cent, and the maximum variation 4.5 per cent. The mean variation from the average shearing strength per linear inch of joint was found to be 5.2 per cent and the maximum variation 7.8 per cent. The results of eccentric tension tests on specimens cut from containers showed that no one of the specimens was markedly weaker than the average for the lot. It is believed that the uniformity of strength thus indicated is of special interest and importance.

3. *Relative Strength of Electrically Welded and Riveted Joints.* The tension tests on specimens of Type A indicated that the resistance to tension applied with a large eccentricity is greater for the riveted joint than for the welded joint. The shear test on specimens of Type B indicated that the resistance to shear per linear inch of joint is greater for the welded joint. Measurements to determine the elastic and permanent protusion of the container heads showed that for the two specimens so tested the welded container withstood a somewhat greater pressure without permanent distortion. In the case of the riveted containers, leakage occurred at the head joints under moderate pressures. In the case of the electrically welded containers there was no leakage at the head joint under any pressure.

4. *Efficiency of Electrically Welded Joints.* While it is customary to speak of the efficiency of a joint, whether welded or riveted, meaning the ratio of the strength of joint to strength of plates joined, the writer does not believe that this ratio is especially significant in the case of electrically welded joints or that any value can be given it that can be regarded as generally applicable.

It is apparent that while the strength of the plates joined is dependent solely on the physical properties of the base metal, the strength of the weld is in great measure dependent on the properties of the filling metal. Furthermore, the per cent excess thickness of the weld, which influences its strength, varies with the thickness of the plates. Accordingly the efficiency of a weld depends on the properties of the base metal, the properties of the filling metal and the thickness of the plates.

The writer believes that the correct method of computing the efficiency of an electrically welded joint is on the basis of a specified minimum strength of base metal, a specified minimum excess thickness of weld and an experimentally determined average strength (per sq.in.) of the metal of which the finished weld is composed.

Elektron.—Lieutenant-Colonel Grard published a note on "Light Alloys Used in Aëronautics" in Revue de Métallurgie, 1921, p. 567, from which the following notes on the German alloy elektron are extracted:

Elektron contains approximately 90 per cent Mg, 5 per cent Zn and 5 per cent Al. Sheets of a similar alloy of French make test as follows:

Elastic limit, lb. per sq.in.	27,000
Ultimate strength, lb. per sq.in.	36,000
Elongation, per cent	22
Specific gravity (33 per cent lighter than aluminum)	1.8

German alloys are advertised with the following properties:

	Alloy "GM"	Alloy "Z"	Alloy "AZM"
Electrical conductivity	22	17	12.5
Temperature coefficient	0.0038	....	.....
Thermal conductivity	0.38	0.38	.....
Specific heat	0.25	0.24	0.24
Thermal expansion	0.000027	....	....
Melting point, deg. C.	650	635	530
Specific gravity	1.74	1.83	1.84

Lowering the temperature from 20 deg. C. to 0 deg. C. lowers the elastic limit, ultimate strength and elongation all about 4 per cent. At 100 deg. C. the elastic limit is reduced 12 per cent, the ultimate strength 5 per cent, and at the same time the ductility increases.

Elektron shavings are flammable, especially when moist. Masses of metal do not burn until melted. It is not attacked by alkalis except ammonia, but is corroded rapidly by acids, even weak organic acids. It reacts violently to salt solutions, chloride and sulphates of heavy metals. It is perfectly resistant to acid-free petroleum products. It may not be used where it is continually wet; atmospheric corrosion builds up a gray coating. Recommended protective coatings are varnish and condensation products like Bakelite.

Elektron must be separated from copper by sheets of aluminum or of fiber.

Elektron cannot be welded or soldered. Cast ingots can be forged or stamped at 225 deg. C.; and drawn or rolled from 400 to 300 deg. C. Extrusion is performed at 400 deg. C. Annealing is done at 400 deg. C.

Properties of Some Steels in the Hardening Range.—W. R. Chapin[1] has made some interesting tests on some oil- and water-hardening steels which harden to the center in ½-in. sections when quenched from about 1,500 deg. C. The steels were ordinary water-hardening carbon tool steels, of the following approximate compositions: C 1.10, Mn 0.3, Si 0.3; nickel-chromium steels with C 0.9, Mn 0.4, Si 0.16, Cr 0.8, Ni 1.5, and a "non-shrinking steel" with C 0.77, Mn 1.48, Si 0.41, Cr 0.06, V 0.19. He would quench these steels, and remove them from the bath when in the hardening range (400 to 500 deg. F., judging by tempering colors), caliper them and make hardness tests quickly before the steel had cooled very much. It was found that oil-hardening steels in and just above the hardening range were non-magnetic, soft to Brinell impressions[2] (180 to 190) but file hard. They were also shrunken, as compared to the original annealed condition, to the extent of a little more than ¼ of 1 per cent in linear dimension.

Magnetism returns slowly to the steels as the temperature drops; the Brinell hardness also increases greatly. Eventual hardness appears to be unaffected by the rate of cooling below the hardening range, and amounts to 650 ± 25. However, there is less distortion and less ultimate change in volume and a better developed martensitic structure after a very slow cooling from the hardening range; hence the logic of removing from the bath at 300 deg. F. and burying in lime, or immersing it for perhaps 15 minutes in an oil bath at 250 deg. F. Shrinkage observed at the hardening range is more than recovered in subsequent cooling to room temperature, despite the concurrent contraction due to drop in temperature, which alone amounts to 0.25 per cent. Total increase in length due to the transformation is therefore about 0.55 per cent, corresponding to a volume increase of 1.65 per cent.

[1] *Transactions*, American Society for Steel Treating, March, 1922, p. 507.

[2] Brinell impressions are rounded at the edges.

Oil-hardened steels tempered 15 minutes at 250 deg F. remained at 683 Brinell and were file hard. Drawing 15 minutes at 400 deg. F. decomposes some martensite, the Brinell hardness remains practically unchanged, but it can be filed slightly. A second 15-minute draw at 400 deg. F. drops the Brinell hardness 25 points, and the sample files easily. If drawn at 800 deg. F., the steel shrinks 0.20 per cent in length from its hardened state.

Water-hardening steels ½ in. square are magnetic in the hardening range, and are not shrunk in volume. If the thickness be reduced to 0.05 in., the same steel hardens readily in oil, and develops the same characteristics discussed at length in the foregoing paragraphs.

All these facts support the theoretical conclusion that the Ar range is depressed to at least 500 deg. F. by quenching; above that temperature, ductile, non-magnetic gamma iron exists. Below that temperature, magnetic alpha iron, of slightly less specific gravity is stable.

Dr. Jeffries pointed out that the volume change recorded in the interval between hardening range and room temperature was about that which would be computed from the change from the space lattices characteristic of gamma iron to that of alpha iron, less the thermal contraction, and disregarding entirely the contraction due to the formation of Fe_3C from molecular carbon and iron. He interpreted the results to mean, therefore, that the formation of martensite involves the allotropic change in the iron, but not the formation of any cementite.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Nitric Acid Fume Recovery.—The invention describes an apparatus designed to recover the nitric acid fume loss from nitrating operations. The apparatus consists of three brick towers in series packed with acid-proof brick or rings. The fumes are drawn from the nitrators by a fan which discharges into the top of the first tower. The gas passes down through the first two towers, over which there is no circulation, the packing surface merely acting as a condenser. The uncondensed fumes rise through the last tower, meeting a spray of water which removes the last traces. The principle claimed is the precipitation of the fumes by the expansion when they enter the tower and by the large condensing surface of the packing. (1,406,353. W. de Sveshnikoff. Feb. 14, 1922.)

Removing Iron and Titanium From Artificial Aluminous Abrasives. — Addition of carbon to calcined bauxite or emery does not effect complete reduction of iron oxide and titanium dioxide during the subsequent fusion. Nor is it possible to extract these impurities from the crushed product. A preliminary roast with an alkaline compound, however, will leave the impurities in a seggregated state so that they can be extracted with acid. Clarence J. Brockbank, of Philadelphia, outlines the process as follows:

To a bauxite (Al_2O_3, 54.8; combined water, 30.5; SiO_2, 4.5; Fe_2O_3, 6.2; TiO_2, 4.0) is added sodium or potassium carbonate in the approximate proportion of 50 lb. to each ton of ore, the resulting mixture being then roasted in a rotary calciner to a temperature of approximately 1,100 deg. C., which is sufficient to remove the combined water. During this roasting process, the alkali combines with the metallic oxides and the silica, forming easily fusible silicates. The ore from the calciner is next mixed with sufficient coke to effect reduction of silica and iron, due allowance being made for the effect of the carbon electrodes, and the mixture fused in an electric furnace. For the above-described bauxite, coke in the proportion of approximately 22 lb. to 400 lb.

of the calcined bauxite will be found sufficient for reduction purposes.

After fusion, the pig or ingot of fused material is broken down, crushed by rolls to powder and then treated with a solution of sulphuric acid in the following manner:

The crushed grains are placed in a lead-lined wooden tank or other suitable receptacle, and sufficient of a 10 per cent solution of sulphuric acid added to completely cover the mass. Heat is applied by means of a lead steam coil, and the treatment continued for approximately 6 hours, when the material is washed and graded to different sizes of grains. (1,402,714; assigned to the Abrasive Co., Philadelphia. Jan. 3, 1922.)

Cellulose Acetate Solution.—Among the solvents which have been suggested for cellulose acetate is ethylene chlorhydrin, CH_2ClCH_2OH. While the acetate is readily dissolved, the solution is so extremely slow drying that it has not been used commercially. By adding an alcohol and an aromatic hydrocarbon to the chlorhydrin, however, a solvent is formed which will dry rapidly. The mixture may consist of: ethylene chlorhydrin, 5 to 25 parts; ethyl alcohol, 15 to 45 parts; benzene, 60 to 25 parts. To the solvent mixture thus provided the cellulose acetate is then added with stirring, the proportion of the latter to the former depending on the character of the product desired. One part of acetate to ten of the solvent mixture will give a clear, limpid solution, which may be readily poured or applied with a brush and which, upon exposure to the air at normal temperatures, will dry promptly, leaving a transparent film that will remain flexible indefinitely. (1,406,224; Mark E. Putnam and William E. Kirst, of Midland, Mich., assignors to Dow Chemical Co. Feb. 14, 1922.)

Production of Ethyl Alcohol From Acetaldehyde.—In the known processes for the production of alcohol by passing acetaldehyde vapors over a catalyst the yields depend largely on the exclusion of oxygen and acetic acid. But when oxygen is completely excluded from the mixture of gases, the resulting alcohol will often contain ether, which is objectionable in certain uses. If a large excess of hydrogen is used in the process, certain impurities such as CH_4, CO_2 and CO are formed, and of these the carbon monoxide is particularly injurious to the catalyst. According to a recent patent all of these objections are avoided by passing over the contact body a mixture of acetaldehyde, an excess of hydrogen and up to 0.3 per cent of oxygen and then carrying out the process by removing the heat of reaction, at least in part, and after separating the alcohol formed, returning the excess hydrogen to the operation. The temperature is kept between 90 and 170 deg. C., because below 90 deg. the formation of alcohol is slow, while above 170 deg. the decomposition of the acetaldehyde rapidly increases.

The yield under such improved conditions is compared with the results of the complete exclusion of oxygen, in the following table:

	Experiment No.				
	66–67	68	69	70	71
Percentage of oxygen in the gases used	0	0.06	0.06	0.1	0.1
Added water, per cent of the condensed products	0	0	2.6	0	2.6
Yield of alcohol, per cent of the aldehyde	88	92	93	94.8	95.2
Content of aldehyde in the condensed products (in per cent)	2	0.15	0.6	0.08	0 07
Content of ether in the condensed products (in per cent)	3.5	1.5	1.5	0.5	0.5

(1,408,794; Theodor Lichtenhahn, of Basel, Switzerland, assignor to Elektrizitatswerk Lonza, of Gampel and Basel, Switzerland. Jan. 17, 1922.)

Dehydrating Petroleum Emulsions.—A series of patents relating to the dehydration of petroleum oils by the use of an electric current were granted on Jan. 31, 1922, to Ford W. Harris, of Los Angeles, Cal., assignor, by mesne assignments, to the Petroleum Rectifying Co. of San Francisco. As is well known, many oil wells produce an emulsion of oil and water and in many cases the water is present in the form of infinitesimal globules. Many investigators have recognized that by subjecting this emulsion to an electric current there is an agglomeration of the water globules, with consequent removal of the water by settling. In most of previous processes the oil which is being subjected to the action of the current is carried in open vessels in which the treating electrodes are suspended. It remained for this inventor to devise a number of novel ways in which the emulsions could be broken without the necessity of providing a plurality of electrodes.

According to patent 1,405,117 a single containing vessel is used and but a single electric field is employed. The body of the fluid is repeatedly circulated through this field and hence repeatedly subjected to its action. By this means the inventor claims to obtain a large capacity at a small initial expense.

In patent 1,405,118 there is described "an electrical dehydrator comprising a tank, a treater, electrodes, a means for impressing an electromotive force between the electrodes, means for circulating oil from a tank through the treater and back into the tank, a pipe for withdrawing clean oil from the top of said tank, a water outlet pipe for withdrawing water from the bottom of the tank and means for introducing the wet oil to be treated into the tank."

The next patent in the series (1,405,119) provides an apparatus in which the emulsion, while being subjected to the electric current, may be safely heated to temperatures considerably above the boiling point of the lighter constituents. Heating some of the very heavy oils, such as those from 9 to 16 deg. Bé., has been found to be of considerable assistance in the coalescence of the water globules. Patents 1,405,120 and 121 deal, respectively, with a system of water controls for electrical dehydrators, and a closed dehydrating tank in which a body of water is constantly retained at the bottom.

A dehydrating apparatus utilizing a very concentrated electric field of small area and through which the emulsion is passed at a high speed is described in patent 1,405,122. A pair of electrodes in axial alignment gives the field. A vertical pipe forms the outer electrode and an iron chain supported within it forms the inner electrode of a dehydrator described in patent 1,405,123. Another dehydrator comprising a tank in which are disposed concentric cylinders adapted to alternate electric polarity and open at their tops and bottoms forms the basis of the next patent. Patents 1,405,125-127 are modifications of dehydrators previously discussed.

The claim of patent 1,405,128, however, depends on a new principle in dehydration—namely, the magnetic displacement of the current-carrying path. In this invention the currents flowing through the emulsions are formed in a magnetic field which is so arranged that the current path is constantly being forced around, thereby coming into contact with fresh portions of the emulsions, so that the whole mass is rapidly dehydrated. According to another process (1,405,129), the emulsion is forced under pressure through a confined space from which air is excluded and in which static charges are caused to take place. The last patent of this series (1,405,130) describes a dehydration which comprises mixing a coarse emulsion with a fine emulsion and subjecting the mixture to the action of the electric current. Apparently the addition of water in the form of a loose emulsion will often very greatly increase the capacity of the apparatus.

Manufacture of Lead Arsenate.—In order to prevent or substantially inhibit the clustering of particles of lead arsenate and the consequent settling when suspended in water, Robert E. Wilson, of Cambridge, Mass., has suggested the addition of a relatively minute quantity of some organic material capable of serving as a protective colloid. He has shown, for instance, that the addition of ordinary glue in the proportion of 0.005 to 0.5 per cent of the weight of the lead arsenate will produce a product which when shaken up with water shows scarcely any tendency to settle in so far as leaving a clear layer at the top of the mixture is concerned. Without such addition even some of the best products leave a substantially clear layer over the settled particles at the rate of ½ in. per minute. It is claimed that the insecticidal power of the product is unimpaired and that its increased covering power makes the improved product more effective and economical to use. (1,393,474; assigned to Pittsburgh Plate Glass Co. Oct. 11, 1921.)

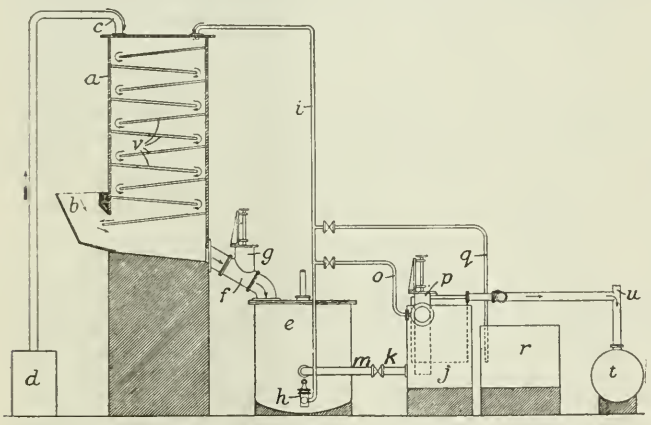
British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Fire Extinguisher.—A fire extinguisher contains a self-propelling mixture of methyl bromide with another liquid or other liquids having vapor pressures below atmospheric pressure at normal atmospheric temperatures, such as carbon tetrachloride, trichlorethylene or dichlorethylene, the methyl bromide being sufficiently volatile to cause the mixture to be self-propellant. The liquid may be discharged from the container by means of a valve, etc., or by snapping off a tube which may be indented or cut for this purpose, the end being sealed by flattening it and bending it over after the container has been charged. (Br. Pat. 172,573. A. Henning, London. Feb. 1, 1922.)

Material for Handling Molten Glass.—Apparatus for handling or working molten glass is made of a metal or alloy having a high melting point, not evolving gas when heated and forming an adherent and insoluble coating of oxide which protects it from attack by the molten glass. Alloys of chromium or aluminum with iron, cobalt, and nickel are mentioned. An alloy of 60 per cent iron with 40 per cent chromium in particular is suggested. (Br. Pat. 172,610. Naamlooze Vennootscap Philips' Gloeilampenfabricken, Eindhoven, Holland. Feb. 1, 1922.)

Sodium Thiosulphate.—The production of strong solutions of thiosulphate from which the salt is crystallized without any evaporation as described in specification 12,599 (1915) is carried out by simultaneously forming sodium sulphite from sodium carbonate and sulphur dioxide, and digesting the sulphite with sulphur, sodium carbonate being prefer-



ably maintained in small excess throughout. Sulphur dioxide from a burner *d* is admitted by a pipe *c* to the top of a tower *a* having shelves *v* down which flows sodium bisulphite solution which contains some sodium carbonate or bicarbonate. Sodium carbonate and sulphur are charged in at *b* where carbon dioxide and nitrogen escape. The reaction mixture passes by a pipe *f* carrying a froth destroying device *g* into a digester *e* which may be jacketed for heating or cooling, and is provided with a stirrer.

Liquor from the digester *e* is raised by a pump *h* and supplied by a pipe *i* to the top of the tower *a*. From the pipe *i* a portion of the liquor may be withdrawn by a pipe *o* and fed through a froth-destroying device *p* to a filter tank *j*, but normally the liquor in the digester *e* is circulated to and from the tank *j* through pipes *m*, *k*, under the action of a stirrer. In the tank *j* a number of vacuum filter plates of known form hang, clear solution being withdrawn from the interior of the plates and led to a store tank *t*. The vacuum pump is connected with a pipe *u*. The liquor may be withdrawn from the apparatus by a pipe *q* to an auxiliary filter tank *r* when it is desired to remove accumulated impurities, such as sodium sulphate, which are insoluble in the thiosulphate solution, but alternatively a proportion of the solid materials separated on the filter plates may be continually withdrawn and rejected. The froth-destroying devices consist of a tubular part containing a spindle carrying disks which are perforated and carry downwardly directed vanes to direct the liquid particles downward. (Br. Pat. 172,858. L. Hargreaves and A. C. Dunningham, Middlewich, Cheshire. Feb. 8, 1922.)

Calcium Carbide.—Agglomerates for subsequent conversion to calcium carbide are manufactured by heating a mixture of limestone with pitch, heavy oils or like heavy hydrocarbons to a temperature above 700 deg. C. for a period from 20 to 40 hours. The limestone is preferably ground before mixing and the heating is continued until the carbonizaton is complete. The preferred form of retort enables the carbonization to take place continuously and the gases used to heat the retort are pre-heated by utilizing the heat evolved by the cooling agglomerate. By spraying the latter with a mixture of hot tar and pitch or by introducing coal or coke-oven gases or some hydrocarbon into the retort during the last part of the carbonization, the agglomerate is protected from moist air during storage by a deposit of carbon produced by the splitting up of the hydrocarbon present. (Br. Pat. 172,685. Alby United Carbide Factories, Ltd., London. Feb. 1, 1922.)

Hydrochloric Acid.—In the manufacture of hydrochloric acid by direct combustion of hydrogen and chlorine, an igniting safety flame, preferably produced by burning a mixture of hydrogen and chlorine, is provided at the junction of the streams of the entering gases, which are so arranged as to cause the combustion to take place in a downward direction. The main gas supply is controlled in order to give equimolecular proportions of hydrogen and chlorine. A shaft furnace having means for cooling the walls may be employed for the process and the gases are introduced at the top through two sets of pipes, the one pair surrounding the other. The larger and outer pair supply the main flame and the inner pair supply the small safety jet with hydrogen and chlorine. To effect complete combustion, the reaction gases are passed preferably after partial cooling over or through contact material placed at the lower end of the furnace and consisting of brick, chamotte, pumice, quartz lumps, etc., with or without metals or metal salts acting as chlorine carriers. The resulting hydrochloric acid is withdrawn at the bottom and passed to absorption vessels. (Br. Pat. 173,300. Badische Anilin & Soda Fabrik, Ludwigshafen on Rhine. Feb. 15, 1922.)

Aluminum Salts.—The invention relates to the precipitation of iron from impure solutions of alumina in mineral acids by partly neutralizing the solution in the presence of iron oxide, which acts catalytically. The iron oxide, after being used, is re-activated by treatment with dilute acids or with an acid solution of alumina having a higher hydrogen-ion concentration than that necessary for the complete precipitation of the iron present. The solution from which the iron is to be removed may be used for this purpose, the iron being subsequently completely precipitated by neutralizing, or by expelling acid by evaporation. The activating process may also be combined with the dissolution of the raw aluminous material in acid. Active iron oxide is introduced during the dissolution of the raw material in acid and the quantities are so regulated that the hydrogen-ion concentration is too great for complete precipitation of the iron but is sufficiently low to cause reprecipitation of most of the iron that has been dissolved. Thus active iron oxide is produced, so that if the raw material contains sufficient acid-soluble iron, when the process has once been started no further addition of iron oxide is necessary. (Br. Pat. 172,944; not yet accepted. Aktieselskabet Labrador, Christiania. Feb. 8, 1922.)

Extracting Copper.—Copper is extracted from its oxidized ores or other oxidized products by converting the oxidized copper contents into cement copper by the action of a reducing agent on a pulp comprising a mixture of the crushed ore or product, water and an acid or salt. Finely crushed ore may be mixed with water, finely divided iron and a small proportion of ferrous sulphate, sulphuric acid or a mixture of ferrous sulphate and common salt, and steam blown through the mixture; or such a mixture containing sulphuric acid may be allowed to stand for some days. The separation of the resulting copper from the gangue and slime may be effected by settling, flotation or other means.

Aluminum or zinc may be used as a reducing agent instead of iron. In some cases a medium such as an acid which has been used for one precipitation may be utilized as a salt solution for subsequent precipitations. (Br. Pat. 172,926; not yet accepted. P. W. Nevill and H. Soanes, Perth, Western Australia. Feb. 8, 1922.)

Refining Anthracene.—Crude anthracene is purified by dissolving it in hot cresols or the mixture of phenol and cresols known as 60 per cent phenol, cooling and filtering and washing the separated anthracene with petroleum ether. Carbazol may be separated from the anthracene so purified by dissolving the anthracene in hot pyridine, cooling, removing the separated anthracene and distilling the pyridine solution to recover the carbazol. The carbazol may be purified by crystallization from toluene and sublimation. (Br. Pat. 172,864. A. Kagan, Brighton, Feb. 8, 1922.)

Book Reviews

THE PRACTICAL CHEMISTRY OF COAL AND ITS PRODUCTS. By *A. E. Findley* and *R. Wigginton.* London: Benn Brothers, Ltd. 140 pp., 23 figures. Price 12s. 6d. net.

The authors indicate that the purpose of this work is to present "one reliable method for determination," including particularly those needs of testing which were taught in the course of fuel technology at the Sheffield University. Teachers of gas and fuel analysis will for this reason doubtless find the book of considerable interest, particularly suggestive of those methods which they should include in their own courses.

The volume is not at all suited to general reference use for the industrial laboratory or for the chemist at gas works or coke ovens in this country. For such workers the volume by A. H. White on the "Technical Gas and Fuel Analysis" or the forthcoming "Gas Chemists' Handbook" of the American Gas Association are distinctly superior. The present volume is much too brief and written from entirely the wrong point of view to serve the commercial or industrial laboratory for which the two other works cited are so admirably prepared. R. S. McBride.

PRECIOUS METALS (LES METAUX PRECIEUX). By *Jean Voisin.* Encyclopédie de Chimie Industrielle, Librairie J. B. Baillière & Fils, Paris, 1922. 264 pp. illustrated.

The first volume of the Encyclopédie de Chimie Industrielle (see Chem. & Met., Dec. 21, 1921, p. 1153) to reach us is that of "Les Métaux Précieux" by Jean Voisin. The author has treated the subject from the point of view of their properties, industrial applications and their economic rôle. The six chapters deal respectively with:

Chapter I, Gold, pp. 1-63, in which are summarized the physical and chemical properties, a brief description of the occurrence of native gold and gold ores, a description of the metallurgical treatments and refining.

Chapter II, Silver, pp. 64-111, in which is followed the same plan as in the chapter for gold.

Chapter III, Platinum and Platinum Group Metals, pp. 112-135, containing brief descriptions on the metals platinum, iridium, palladium, rhodium, osmium and ruthenium.

Chapter IV, pp. 136-151, is a very interesting review of the past and present economic rôle of precious metals.

Chapter V, pp. 152-205, deals mainly with assaying the precious metals used for coinage and jewelry.

Chapter VI, pp. 206-239, contains succinct descriptions of the production of precious metals, salts, gold and silver plating, applications to electrical industries, medicinal uses, photography and platinum as catalyzers.

The bibliography, pp. 241-256, is divided into four distinct groups—namely, (1) historical, (2) physical and chemical properties, (3) mining and metallurgy and (4) refining and applications. J. S. Negru.

ALUMINIUM AND ITS ALLOYS. By *C. Grard,* translated by *C. M. Phillips* and *H. W. L. Phillips.* 184 pages, 17 plates and 83 figures. New York: D. Van Nostrand Co. Price, $5.

"Aluminium," by Grard, is a book for discriminating readers, but they should be able to discriminate between the aluminum and the dross which, unfortunately, clings to the book in spots. One's criticism of the work is tempered, however, by the fact that there is somewhat of a dearth of authoritative books on the subject, and this book is a creditable effort to supply the existing demand for information on the properties and heat-treatment of aluminum and its alloys. According to the title page, the subject is "Aluminium and Its Alloys; Their Properties, Thermal Treatment and Industrial Application," and the principal shortcomings of the book may be traced to the fact that the author's data and selection of data are inadequate to cover the field outlined.

The method of producing aluminum is tossed off in six pages, and statistics on the world's production in another six pages. One wonders, in reading the description of the physical properties of aluminum on page 15, whether the same kind of judgment as used there was exercised in selecting data for the succeeding sections of the book. For example, the atomic weight of aluminum is given as 26.9 instead of 27.0, the thermal conductivity as 36 (silver=100) instead of 51 or 52, and the melting point as "about 650 deg. C," which latter figure is not a very close approximation to 658, considering the state of the art of pyrometry. On a succeeding page the argument would have been just as strong if the melting point of alumina had been given as 2,050 deg. C. instead of 3,000 deg. C. It would have been a kindness for the translators to have called these and sundry other errors to the author's attention in preparing this edition.

In discussing the mechanical properties of aluminum, the author is more at home, and presents some very interesting data obtained for the French Aëronautical Service at various governmental and private laboratories. Quite a comprehensive series of data on the working and annealing of aluminum is given. The author's conclusions with respect to cold work might have been modified if he had obtained more data. The statements that "the maximum cold work, beyond which deterioration and disintegration may set in, is reached when the tensile strength is approximately doubled" and "that 200-300 per cent cold work is the maximum for the working of aluminum" are scarcely precise, to say the least. The tensile strength of aluminum will still be found increasing when the cold work has passed 4,000 per cent as cold work is defined by the author (ratio of the reduction in area to the final area). Aluminum sheet having about 900 per cent of cold work, as thus defined, is a commercial article. The author's curve is defined by four points at 0, 50, 100 and 300 per cent cold work.

In the annealing experiments, the temperatures of the specimens were controlled by immersion in an oil bath or a bath of fused salts. Such a method is much superior in point of precision to the more customary method of heating in an oven or air bath, and the results are correspondingly more reliable.

The second half of the book is devoted to the alloys of aluminum. A useful description of the properties of the aluminum-copper, aluminum-zinc-copper and aluminum-magnesium alloys, as cast, is followed by a section on the heat-treatment of aluminum alloys containing copper and magnesium. The last section of the book deals with the copper-rich aluminum alloys commonly called the "aluminum bronzes." In the appendix will be found the French Aëronautical specifications for high-strength aluminum alloys.

The book is a useful contribution to the metallurgy of aluminum, and is particularly interesting as reflecting the experience and experiments of the French Aëronautic Service. It is not, however, an authoritative work, for the reasons above indicated. Junius D. Edwards.

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

No Shortage of Nitrates for Fertilizer, Says Secretary of Agriculture

A statement of the Secretary of Agriculture in reply to a telegram sent to him by Andrew L. Felker, Commissioner of Agriculture for New Hampshire, states his opinion that there is no shortage of nitrates among the fertilizer companies. Mr. Felker complainted that fertilizer companies are unable to get nitrates to fill farmers' fertilizer orders and as a result the latter are seriously handicapped. Secretary Wallace replied in part as follows:

"I am not able to understand the basis for the belief that there is a serious shortage of nitrates and that fertilizer companies are not able to supply fertilizer needs of farmers because of this shortage. Apparently, from the record of imports during the past two years, there has been no shortage of nitrates. The normal importation of nitrate of soda before the war was about 600,000 short tons, and I am told that of this about 250,000 tons were used for fertilizers. In 1920 we imported 1,480,519 short tons of nitrate of soda, or something more than a two years' normal supply. This would have supplied the demand for fertilizers for 1920 and for 1921 and leave a surplus of approximately 200,000 tons for 1922. The fertilizer tonnage for 1921, however, is believed to have been little more than one-half the expected tonnage, and it is therefore reasonable to believe that the nitrate surplus for 1922 was considerably more than 200,000 tons.

"In 1921 nitrate of soda imports amounted to 413,474 short tons. In that year also the War Department released 80,000 tons, making available during that year 493,474 tons, in addition to the more than 200,000 tons of surplus presumably carried over from 1920. In January and February of this year we imported 32,065 short tons. There has been no lack of available nitrate of soda in Chile, for on June 30, 1921, there was said to be a visible supply of 2,435,000 long tons, while the most hopeful estimate of the world demand was about 1,600 000 long tons.

Companies Do Not Buy War Department Surplus

"Now, as to the statement that fertilizer companies are not able to buy nitrates, permit me to call your attention to the fact that on Thursday of last week the War Department offered at public sale 40,000 tons of nitrate, the conditions being that in quantities of 500 tons or more the War Department might reserve the right to demand an equivalent amount of nitrates within ninety days, but sales of less than 500 tons would be considered final sales. I am told that a large number of representatives of fertilizer, powder and chemical companies attended this sale in Washington. In all there were about 11,000 tons definitely sold, but from the report of the sale evidently less than 2,000 tons were bought by fertilizer companies, the remainder of the 11,000 tons going to chemical and powder companies. I do not know why fertilizer manufacturers who are complaining of the difficulty of getting nitrates did not attend this sale and buy when they had an opportunity. One company made a bid for 23,000 tons under the condition which gave the War Department the right to demand repayment in nitrates, but the price bid was considered by the War Department altogether too low, and I am informed that this sale was canceled.

"Reasoning from the statistics quoted in the foregoing, I think you must agree with me that apparently there is no shortage of nitrates to meet the needs of fertilizer manufacturers. Had there been such shortage as seems to be indicated by your telegram it would seem that fertilizer companies would have taken advantage of the offerings of the War Department last week."

Rival Muscle Shoals Offers Discussed—Farm Bloc Backs Development

In testimony before the Senate Agricultural Committee, T. W. Martin, president of the Alabama Power Co., emphasized that the proposal submitted by his company conforms with the provisions of the Federal water power act and if given a lease, the company would operate under the supervision of the Federal Power Commission. The company has prepared a pamphlet embodying the terms of the offer and the letters of comment by Secretary Weeks and Mr. Martin.

The agricultural bloc of the Senate, composed of an influential group of Senators determined to secure legislation in the interest of the agricultural industry, and which has heretofore scored numerous legislative successes, has come out strongly for the development of the nitrate project. In a Senate speech, Senator Capper, of Kansas, chairman of the bloc, said the organization favors the development of the project, as it will contribute to a permanent and prosperous system of agriculture. He believes that work should be resumed on the fertilizer and power plants on the Tennessee river, and says it is possible to reduce the nation's fertilizer bill from $250,000,000 to $125,000,000 if the Muscle Shoals program is carried out.

One of the first decisions reached by the House Committee on Military Affairs was to eliminate Dam No. 3 and the Gorgas steam plant from any present consideration. It is the intention of the committee to present an inventory of all unencumbered property which the government has at Muscle Shoals. This list, along with certain decisions of the committee, will be presented to those who have made bids and each will be given an opportunity to modify his offer to conform. The committee now is engaged in an examination of the Ford offer.

Speaking before the Kiwanis Club in Detroit, Ernest G. Leibold, personal secretary to Mr. Ford, dwelt on the theme that the world has reached a stage where gold can no longer function as an international medium of exchange. He pointed out Mr. Ford's scheme to raise the $30,000,000 for the completion of the project by the issuance of special currency which will be retired in 25 years by the accumulating 4 per cent interest that Mr. Ford wishes to pay annually, "without one dollar of interest having been taxed on the public."

Structural Steel Society Disbands Because of Depression and Government's Attitude

After 11 years of activity the Bridge Builders and Structural Society will disband at the end of this month, according to a recent announcement from its headquarters in New York. The society has been one of the so-called open-price associations whose purpose has been to spread the information among members of the prices at which the structural steel fabrication projects were taken. The decision to disband was made because of doubt as to the government's attitude toward the society and its practices and to the depression in the steel industry in 1921. Besides the open-price discussions, one of the activities of the society has been the gathering of monthly statistics as to the amount of fabricated steel contracted for throughout the country. These figures are taken by steel experts as one of the barometers of the steel industry. The Structural Society has volunteered to continue this latter work.

The decision to disband has been known in inner circles for several weeks. Prices have not been exchanged since the first of the year. The membership embraced the leading independent steel fabricators.

Regulating the Activities of the Trade Association

Of late the attention of the business public has been focused on the trade association. It has been recognized as an element of growing importance in our industrial program, but with this realization has come the need for a better understanding of its activities, particularly those in which perplexing legal questions are involved. The discussions in the newspapers and technical press by lawyers, economists and business men have served to clarify certain of the relations of the trade association to industry. It remained for the recent Trade Association Conference held under the direction of Secretary Hoover to emphasize the desirability for defining the government's relation to the trade association.

The Edge-McArthur Resolution

It was with this in view that Senator Edge of New Jersey and Representative McArthur of Oregon introduced legislation in Congress for the purpose of definitely establishing the status of the trade association. They proposed a Congressional investigation by a commission composed of three Senators and three Representatives which by next December should report legislation defining the rights and limitations of co-operative organizations as distinguished from illegal combinations in restraint of trade. The resolution points out that business is now hesitating because it is unable to secure guidance which will clearly indicate proper lines of conduct.

The Edge and McArthur bills, which supplement their joint resolution, propose that trade associations shall be under the jurisdiction of the Federal Trade Commission. Unless excused by it, each association would be required to file with the Federal Trade Commission a statement of its general character and proposed activities, the names and addresses of its members, officers, minutes of meetings and resolutions or agreements, expressed or implied, whether between members of the association or between the association or its members and others.

The bills would also require trade associations to file with the commission statistics collected by them as to production, shipments, stocks, contracts, prices, credit information, and all others respecting the trade. The commission may, if it sees fit, give publicity to such statistics for the public interest, and unless prohibited by the commission the association may distribute among its members statistics which have been filed with the commission.

Resolution Is Sidetracked in Senate

The resolution was introduced to the Senate on April 17, but met with considerable opposition. Senator King of Utah expressed the fear "that the business men and manufacturers of the country, profiting by their experience in the war, when we winked at combinations in restraint of trade and destructive of competition, want to perpetuate that condition and want the government to modify the Sherman anti-trust law so that they may organize to throttle and destroy competition and build up gigantic monopolies."

Senator Hitchcock, failing to see the need for the investigation, declared that no other of our laws has been as thoroughly defined by the courts of the United States as the anti-trust law. Senator Edge contended, however, that the Supreme Court's decision in the case of the Hardwood Manufacturers Association has left industry in a state of acute legal and economic uncertainty.

Further opposition was developed by Senator Cummins, who had helped to frame the original Federal Trade Commission act. Finally Senator Walsh of Montana urged that the resolution should be referred to the Judiciary Committee, and since there was no objection it was so ordered.

On April 19 the resolution was again brought up, but by a vote of the Senate it was displaced by other business. Senator Edge then gave notice that he would ask the Judiciary Committee to hold public hearings on his bill. It is reported, however, that Chairman Nelson of the Judiciary Committee is not inclined to order hearings at this time, in which case there is but little chance of the resolution being revived.

Gains From Open-Price Associations Are Greatly Exaggerated

Trade association practices which come under any suspicion whatever constitute such a small percentage of the benefits accruing from the work of these organizations that there is no justification for the continuance of questionable activities. This point was brought out strongly at the Trade Association Conference held at the Department of Commerce. It was shown that only seventy out of 3,000 organizations can be classed as out and out open-price associations. Even among the open-price associations the opinion was expressed that 90 per cent of the benefits to members come from other activities. One of the conclusions that may be drawn from the meeting is that the value of so-called open-price statistics has been exaggerated.

While it was brought out clearly at the meeting that the legality of open-price statistics has not been passed upon and that associations doing such work cannot be denounced as lawbreakers, particularly when their figures are made public, yet it was made perfectly plain that the Department of Commerce will not co-operate with that type of organization. No one will be surprised if the Department of Justice should institute proceedings against such associations. At any rate, the Department of Commerce is not going to jeopardize its usefulness to other trade associations by co-operating with those which are operating within the twilight zone.

Hoover Favors Publicity but No Governmental Control

In this general connection, those high in authority are impressed particularly with the inhibition against secrecy which runs through the opinion of the Supreme Court in the Hardwood Lumber case. Since the Supreme Court seems to aim particularly at statistics which are available to members only of associations, the Department of Commerce is interested in giving evidence that publicity is taking place. There is no desire on the part of the department, Secretary Hoover points out, to force any association to file its figures with his bureaus. In fact the department is entirely out of sympathy with legislation giving actual control over any trade association activity. There are a few instances, one of which is in the chemical industry, where statistical information as to important basic commodities is refused by manufacturers. It is admitted that legislation may be required to remedy that situation.

The Department of Commerce has on file a long list of the constructive things which trade associations can do. The list is growing. It is believed that its growth will be accelerated as trade associations realize that they have been covering only a portion of their field. Heretofore attention has been concentrated largely on matters intended to accelerate production. Very little has been done toward improvement in distribution—an area that should be closely studied. Sight also seems to have been lost of the fact that no restraint of trade is involved when buyers and sellers get together. Were trade associations to arrange for committees of buyers to confer with committees of sellers, it is believed that much waste could be eliminated and the spread between the price obtained by the producer and that paid by the ultimate consumer could be narrowed materially.

Chemical Plant Equipment Manufacturers Meet to Organize Association

Plans for the organization of an association of chemical plant equipment manufacturers will be consummated at a meeting to be held at the Chemists' Club, New York, on May 10 at 10 a.m. After completion of the details of organization, plans for future activity will be discussed, at which time representatives of the Chemical Exposition, the Boston Textile Show, the New York Automobile Show and the Ice Cream Supply Dealers' Association will be heard. Representatives of firms who may become members of the new organization are invited to be present at these meetings.

Patent Working Clause Hearings Postponed

Hearings on pending legislation requiring the operation of patents which were scheduled to reopen before the Senate Patents Committee on April 18 have been postponed to a date to be announced later. The explanation offered is that with the tariff bill before the Senate members of the committee cannot take the time to study such an important proposal as is embodied in the Stanley bill.

Original Purpose of Dye Investigation Lost In Discussion of Embargo System

Sight seems to have been lost of the monopoly charges made against the domestic dye industry in the investigation being conducted by the Shortridge sub-committee of the Senate's Judiciary Committee. During the past week the hearing has resolved itself largely into a discussion of the respective advantages and disadvantages of the selective embargo system.

The questions asked consumers of dyes usually reveal that the witness is impelled by a desire to get dyes at the lowest possible price. These witnesses frequently are embarrassed by efforts to explain their position. If they were allowed to take advantage of the prices Germany is willing to make at this time, it is brought out repeatedly, they soon would be left to the tender mercies of the manufacturers in that country, who would not be restrained as they were formerly by the fear of possible American competition. If after all the expenditure of capital and effort and after the advantages which have come from 8 years of embargo, it is found impossible to build up a dye industry in this country, it is certain no other effort will be made if this one fails. It has been brought home to the consumers of dyes several times during this hearing that instead of placing obstacles in the way of the development of the domestic industry, they above all others should be interested in encouraging whatever steps are necessary to insure its permanency. Witnesses for the consumers dislike to talk about the value of the dye in relationship to the selling price of the article into which it enters. One witness refused point-blank to put such prices into the record. In several instances these witnesses were not closely in touch with the situation. The American control over imports was blamed for delays caused by the strikes in Germany. On the whole their testimony has been theoretical.

Textile Representative Denounces Embargo

Ward Thoron, treasurer of the Merrimack Manufacturing Co., of Lowell, Mass., and Huntsville, Ala., manufacturer of plushes, velveteens, corduroys, moleskins and fustians, declared that the embargo puts an intolerable burden on the textile trade. He expressed the conviction that unless the dye industry can get along without the embargo and licensing system, the American dye users cannot afford to continue to patronize it. "American manufacturers must abandon the dyes they cannot make without more protection," he said. "I don't object to a tariff of 100 per cent protection," continued the witness, "but I do object to the license and embargo system. If these people can't manufacture at 100 per cent protection, let them perish."

When the witness was requested to show the proportion of the cost of dyes to the selling price of his goods, he declared, "That I absolutely refuse to do. It has nothing to do with the costs. The selling price varies from time to time and depends upon supply and demand."

Senator Shortridge attempted to bring the testimony back to earth by asking the witness his opinion as to the existence of a monopoly, but his ideas on this subject seemed vague.

Mr. Thoron said that a group of Massachusetts textile men had, in July, 1921, addressed a circular to a number of dye users asking their opinion on the embargo system. The result was sixty-three replies against and thirteen in favor of the selective embargo system. "Frankly," he added, in closing his testimony, "I dislike the teamwork among the Chemical Foundation, the bureau of investigation of the Alien Property Custodian's office, the Textile Alliance and the American Dyes Institute with the dye manufacturers. It augurs no good to the dye users."

F. S. Dickson, head of the dye and chemical section of the customs division, Treasury Department, expressed the opinion that some of the complaints of the textile men against the embargo were due to lack of funds to maintain a laboratory and a trained technical staff. Mr. Dickson thought that some arrangement might be worked out later whereby importers might keep surplus stocks of foreign dyes on hand.

King Still Wants Examining Counsel

A letter was read into the record from Senator King in which he reiterated his statement that the committee should have counsel to examine witnesses and mentioning Samuel Untermyer as the logical man for the job. Senator King also replied to suggestions that he should cross-examine witnesses himself, saying that he doubted the propriety of such a procedure, inasmuch as he had introduced the resolution calling for the investigation.

Charges of Falsified Invoices Against I.G.

Charges, accompanied by documentary evidence, that the German dye monopoly has falsified consular invoices for the purpose of furnishing dyestuffs to importers in this country at prices less than those charged for the reparations dyes by the Textile Alliance are contained in a letter under date of April 11 from A. M. Patterson, president of the Textile Alliance. Under the emergency tariff, duty on the reparations dyes is assessed on the home consumption price or the export price, whichever is higher. It is therefore necessary to have the German manufacturers certify in the consular invoices the export price, as well as the home market price. By certification of erroneous prices in the consular invoices, the dyes were subject to excess duties for overvaluation and penalties for undervaluation, neither of which is recoverable.

The letter submitted consular invoices of the Bayer Co. showing that the company sold alizarine blue-black B to the Textile Alliance at $2.85 per kilogram but to a United States importer at $1.87. The shipment to the importer was undervalued and a similarly worded invoice with different figures and signed by the same signature of the Bayer Co. was sent to the Textile Alliance.

Knitting Mills Not Represented in Alliance

George Deming, counsel for the National Association of Hosiery and Underwear Manufacturers, appeared in opposition to the embargo. Mr. Deming will be remembered as having handed Senator Shortridge a letter attacking the conduct of the hearings some weeks ago. The substance of this letter was later repudiated by J. N. McCullaugh. manager of the association.

The two principal reasons for his clients' opposition to the embargo are, first, that it increases production costs and, second, that there is no sound justification for singling out the dye and organic chemical industry as the only beneficiary of special protection. If the embargo is applicable to the dye and chemical industry, it is more applicable to other American industries, he declared.

In answer to questions, Mr. Deming said he believed that competition exists among manufacturers at the present time, and that the administration of the embargo is honest and plays no favorites.

Mr. Deming's testimony was interrupted several times by Samuel Isermann, president of the Chemical Co. of America, who demanded to know who pays the witness. The lawyer replied that he was not paid by the association but by some of its members and other consumers of dyes. The embargo was attacked by the witness as hampering, restrictive and involved with red tape. He also attacked the Textile Alliance, declaring it presumptuously took upon itself the self-imposed task of speaking for the entire textile industry when from 2,600 to 2,700 knitting mills, constituting an important part of the textile industry, were not represented in the Alliance.

Some of Mr. Deming's remarks precipitated a discussion as to the quality of American dyes, Dr. Isermann declaring that American dyes are at least equal in quality to any others for dyeing hosiery.

Infringement Suit on Stainless Steel Against Ludlum Steel Co. Dismissed

The suit of the American Stainless Steel Co., of Pittsburgh, alleging infringement by the Ludlum Steel Co., Watervliet, N. Y., of the Brearley and Haynes stainless steel patents, has been dismissed by the United States District Court at New York. The court on April 13 issued a lengthy decision dismissing the complaint on the ground that no infringement was shown.

The Brearley and Haynes patents cover high-chromium, low-carbon steel for producing stainless cutlery. The Ludlum Steel Co. has patents covering chromium-silicon alloy steel. The Ludlum steel, although high in chromium, contains less chromium than the steels put out under the Haynes and Brearley patents. The Ludlum steel is low in carbon, as are the steels made under the Brearley and Haynes patents, but it runs high in silicon, unlike the Brearley and Haynes steels. In its complaint the American Stainless Steel Co. alleged that the Ludlum company's steel constituted an infringement of the Brearley and Haynes patents, claiming that the addition of silicon was made in order to evade the two patents and had no effect upon the stainlessness of the steel. The Ludlum Steel Co., in defending the action, denied that it used silicon to evade the Brearley and Haynes patents, but claimed that the addition of silicon made the product a different and better one.

The court held that the Ludlum steel without the silicon would not constitute an infringement of the Haynes and Brearley patents; that without the silicon the steel would not become stainless upon hardening as disclosed in the two patents and that the addition of silicon to the steel, while making it stainless, could not create infringement, because the stainless result was obtained by something not disclosed in the Haynes and Brearley patents.

The court did not pass upon the validity of the Brearley and Haynes patents, but merely held that the silicon-chromium steels of the Ludlum Steel Co. do not infringe.

Pittsburgh Meeting, American Society for Steel Treating

Technical sessions as follows are planned for this occasion to be held at the auditorium of the Pittsburgh Station, Bureau of Mines, located in Schenley Park:

THURSDAY, MAY 25, 1:30 P.M.

Professor McIntosh, Carnegie Institute of Technology, "Fiber in Steel and Iron."

W. B. Crowe, metallurgist, Carnegie Steel Co., "Mass Influence on Heat Treating."

FRIDAY, MAY 26, 1:30 P.M.

Mr. Cox, R. D. Nuttall Co., "Abrasive Qualities of Carbon and Alloy Steels."

J. A. Succop, Heppenstall Forge & Knife Co., "The Importance of Properly Heating and Cooling Steel."

Mr. Smith, Union Spring & Manufacturing Co., New Kensington, Pa., "Manufacture of Springs."

Mr. Grossman, Electric Alloy Steel Co., Youngstown, Ohio, "Shrinkage of High-Speed Steels."

A banquet will be held at the University Club Thursday evening, and a smoker at the Bureau of Mines Friday evening. Opportunity will be extended to visit several steel mills and manufacturing plants.

Would Extend Maryland Clay Workings

The Commercial Club, Frostburg, Md., has concluded arrangements with the Bureau of Mines, Washington, D. C., for a complete and exhaustive investigation of clays in Allegany County, particularly in the western section, in the vicinity of Frostburg. Clay from this district has been used for many years past for the manufacture of brick, as well as hollow tile and certain other burned clay products, but it is believed that the forthcoming investigation will indicate a wider range of use for the material, showing the commercial value for other clay products. The clay mines are adjacent to extensive coal properties, making unusually fine plant site conditions.

Western Reserve University Offers Summer Courses in Chemistry

Announcement has been made by the Western Reserve University of a series of courses in chemistry especially designed for teachers and for students desiring work of senior college or graduate grade. These courses will continue for 6 weeks, from June 19 to July 29, and will include studies in general inorganic chemistry, chemistry of the metals, organic chemistry, qualitative and quantitative analysis, chemical microscopy, glass blowing and applied electrochemistry. Further information may be obtained by addressing the registrar, Cleveland School of Education, Cleveland, Ohio.

Harding Shows Interest in Activities of Federated American Engineering Societies

The work of the Federated American Engineering Societies was discussed April 11, when Mortimer E. Cooley, the president of the Federation, and L. W. Wallace, its executive secretary, conferred with President Harding. The President showed keen interest in the organization and recalled the part which Secretary Hoover took in its formation.

Dean Cooley outlined the work that the Federation plans for the immediate future and called the attention of the President to a list of the activities which have concerned the Federation since its foundation, 17 months ago. The list is as follows:

Investigation of industrial waste; participation in the settlement of jurisdictional disputes among unions of the construction industry; study of the relative merits of the eight-hour and twelve-hour shifts in continuous process industries; actively supported Patent Office relief bill, topographic survey bill, business cycle bill, railway transportation bills, and legislation providing a commission status for sanitary engineers of the U. S. Public Health Service; study of the Muscle Shoals and Great Lakes-St. Lawrence waterway projects; participation in the Unemployment Conference's investigation of business cycles; participation in the activities looking to the reorganization of the federal government's executive departments, including the bill providing for a Department of Public Welfare, and particularly proposals looking to the establishment of a Department of Public Works; participation in numerous conferences called by the Department of Commerce.

Institute of Metals

A joint meeting of the Institute of Metals Division of the A.I.M.E. and the American Foundrymen's Association will be held in Rochester, N. Y., June 5 to 9, 1922. (Headquarters at Powers Hotel.) A preliminary announcement of the technical program includes the following:

"Physical Properties of Cartridge Brass," by C. Upthegrove and W. G. Harbert, of the Department of Chemical Engineering, University of Michigan, deals with the effect of annealing and rolling.

"Electrical Properties of Nickel and Monel Wires," by M. A. Hunter, F. M. Sebast and A. Jones, of Rensselaer Polytechnic Institute.

"Blue Constituent in Manganese Bronze," by E. H. Dix, Jr., Air Service, U. S. A., at Dayton, Ohio, shows the effect of this little known constituent as determined by experiments at McCook Field.

"Gas Absorption and Oxidation of Non-Ferrous Metals," by Bruno Woyski and John W. Boeck, metallurgists of the Lumen Bearing Co.

"Testing Artillery Cartridge Cases," by J. Burns Read and S. Tour. It summarizes, as far as possible, the metallurgical information and experience gained by the Ordnance Department during the war on the manufacture of artillery cartridge cases, describes the tests to which the cases were put, and summarizes the knowledge and experience gained in this testing.

Upon publication, copies of these papers will be mailed to interested parties who send a request to the secretary of the Institute, 29 West 39th St., New York City.

N. J. Chemical Society on Record for American Valuation—Harkins Talks on Isotopes

At a well-attended meeting of the New Jersey Chemical Society in Newark, N. J., on April 17, all the officers were re-elected for the coming year by unanimous vote. A lively discussion on the chemical schedule of the tariff bill was precipitated by a resolution introduced by N. W. Haynes, editor of *Drug and Chemical Markets*, urging the adoption of rates based on American valuation. The resolution was amended and adopted in the following form:

"Therefore, be it resolved that we, the members of the New Jersey Chemical Society, do urge upon Congress the adequate protection of the chemical industry by the prompt adoption of tariff schedules on chemicals based upon American valuation except those chemicals already adequately protected by an embargo."

W. D. Harkins, professor of chemistry at the University of Chicago, addressed the meeting on "Isotopes and the Structure of Atoms." Prof. Harkins gave a sketch of developments which led up to the discovery of isotopes and showed a number of photographs of the path of alpha particles emanating from radioactive substances and the disintegration of the atom. He also described the apparatus and method used for isolating the isotopes of chlorine and mercury and showed how the atomic weight of the elements depends upon the number of isotopes which form the atom.

Prof. Harkins explained his whole number rule, which may be stated very simply as follows: The atomic weight of any pure isotope, with the exception of hydrogen, is almost exactly a whole number. It is evident that, if this rule is valid, any element of which the atomic weight is not a whole number must consist of two or more isotopes. With the aid of a chart showing the atomic number and atomic weight of all the known isotopes, he explained the method used for predicting the number of isotopes and their atomic numbers that an element should have.

Prof. George B. Pegram of Columbia University and Prof. George Winchester of the State University of New Jersey led in the discussion which followed.

Tentative Program Announced for Atlanta Meeting of A.S.M.E.

The tentative program for the spring meeting of the American Society of Mechanical Engineers, which is to be held in Atlanta, Ga., May 8 to 11, includes a number of features of interest. Headquarters will be established at the Piedmont Hotel, and numerous social features and excursions to points of local interest will be interspersed in the technical sessions. A discussion of the Muscle Shoals nitrate plant and the nitrogen supply by Major J. K. Clement will feature one of the general meetings. A paper on centrifugal castings will be presented by Leon Cammen at the same session, and W. K. Lewis will submit a paper on the evaporation of a liquid into a gas. Among the subjects scheduled for the power sessions are "Power Development in the Southeast," by Charles G. Adsit, "Economics of Water Power Development," by C. A. Mees, and "New Developments in Hydro-electric Design," by J. A. Sirnit. A symposium on welding will be held at which will be presented a number of papers dealing with the strength of electrically welded pressure containers and other phases of the subject. Plans for the entertainment include a visit to Muscle Shoals.

A.I.M.E. Co-operates With Government in Survey of Mineral Resources

Mining engineers who have specialized in war minerals are to be designated to co-operate with army officers in the study of the strategic mineral situation in the hope that peace-time activities can be directed along lines which will contribute most to the national defense in case of an emergency. The entire subject of war minerals was discussed in Washington last week by Pope Yeatman, J. E. Spurr, George Otis Smith, H. Foster Bain and Arthur S. Dwight, who are members of the committee of the American Institute of Mining and Metallurgical Engineers requested to co-operate with the War Department.

New Infringement Suits by Patentee Claiming Interest in Minerals Separation Patent

Infringement suits have been brought against the Kennecott Copper Co., the Nevada Consolidated, Ray and Chino companies, with home offices in Maine, and Federal Mining & Smelting, Belmont & Wagner, Calaveras Copper Co., and Miami Copper Co., Delaware corporations, by J. W. Wolf, for infringement of his patent No. 787,814, April 18, 1905.

It is explained that the delay in bringing infringement suit until within a few days of the expiration of the patent has been due to the fact that Mr. Wolf was financially unable to undertake the prosecution of such suits, and also that it had not been possible for him to ascertain the facts as to the operations of those who had been using his process.

A few months ago Mr. Wolf brought a suit against his financial principals, alleging that it was through their failure to carry out the terms of their contract that he was deprived of enormous royalties which were then being paid to others—namely—Minerals Separation, Ltd. It is an interesting fact that Mr. Wolf went to Sulman & Picard, as consulting independent engineers, to have them develop the details of an improvement in bulk oil process for the use of sulpho-chlorinated oils, in the year previous to the issuance to Sulman, Picard and Ballot of the now famous Minerals Separation patent.

More Engineers Being Employed

Distinct improvement in the unemployment situation in the engineering profession is reported by the Federated American Engineering Societies' Employment Bureau, 29 West 39th St., New York. During the first quarter of this year 778 available positions were sent to the bureau, as against 347 for the same period in 1921. The number of men placed showed an increase of 41 per cent, rising from 293 during the first 3 months of last year to 415 during the quarter just passed. The number of new men registering with the bureau fell from 552 last year to 421 during the first 3 months of this year.

Many of the positions available are in the junior grades, but there is an increased number noted in the higher grade openings which are sent in, practically unheard of at the same time last year.

The gradually increasing activity does not appear to be confined to any particular line, but is more or less general. The architectural field seems to be fairly busy, and building construction shows somewhat of an onward trend. General manufacturing indicates slow improvement. There are many large projects which are rapidly reaching the definite stage, and some big work will probably be opened up within the next few months.

It is stated that business men are gradually realizing that the engineer is not a narrow specialist, but is a trained man capable of handling a non-technical job.

English Ceramic Society Plans Tour Through Scandinavian Pottery Plants

The Ceramic Society of England has arranged a tentative program for its foreign trip to Sweden and Denmark which is to take place from May 27 to June 10, 1922. The trip will include visits to potteries at Gothenberg, the power plant, carbide, graphite and smelting plants at Trollhättan, "the Swedish Niagara Falls," and the works of the Kopparbergs Bergslag, which is the largest private works in the country and manufactures iron, steel, paper, copper and timber. Visits will also be made to the universities and schools at Upsala and Stockholm and the pottery plants in this vicinity. The refractory brick plants at Höganäs and near Copenhagen will entertain the visitors, as will the china works around the city. The party will return to England from Copenhagen.

A special train will be provided to carry the party from town to town, so that early morning starts will not be necessary. Considerable time is left open so that members will have opportunity to visit points of individual interest.

French Societies Move to Assure Funds for Compilation of Annual Tables

The confederation of French scientific societies has renewed for the year 1922 its contribution of 40,000 francs in support of annual tables of constants and physical, chemical and technological data. The total subscription in France to this project during the year 1921 was 80,000 francs.

At the approaching meeting of the International Union of Pure and Applied Chemistry which is to be held at Lyons in June, the matter of organizing the work of annual tables upon a solid financial basis will come up for consideration. This important international project has had a very precarious existence since 1914 and the fact that the work has been continued at all has been due to the efforts of the general secretary, Dr. Charles Marie. Plans for providing a certain and sufficient budget for the work during the next 5 years are in preparation, based upon definite annual contributions from the various countries in the International Union.

Fellowships in Mining and Metallurgy Announced by University of Utah

Announcement is made by the department of mining and metallurgical research of the University of Utah of a number of fellowships in that department during the year 1922-23. This department is maintained in connection with the Utah Section of the United States Bureau of Mines and is a department of co-operative research maintained by these two organizations. The problems which are to be continued during the coming year include ore-dressing problems dealing with crushing and flotation, study of the chemical reactions involved in the chloridizing roasting, oil-shale technology, hydrometallurgy of zinc and problems inherent in the chloridizing volatilization process, including equilibrium measurements and fume treatment.

These fellowships are open to college graduates with a good training in chemistry and applications will be received for them up to May 15, 1922. Applications should be addressed to J. F. Merrill, Salt Lake City, Utah.

Newly Organized Company Will Erect Large Pulp and Paper Mill in Canada

The Bathurst Company, Ltd., has been organized with a capital of $3,000,000 for the purpose of taking over 200 square miles of timber limits, east of Prince George, B. C., and establishing a paper and pulp factory that will have an output of 150 tons per day and will give employment to close to 1,000 men. Among those interested in the new organization are Angus and H. K. McLaren, of Montreal; Frank Jones, of the Canada Cement Co.; Peck Bros., of Pennsylvania and Lord Beaverbrook, who owns the *Express* and several other papers in England. The construction of the plant is to be started about June 1. The organization of the company has been in contemplation for some time, and a number of concessions have been obtained from the British Columbia Government. When completed it will be the largest single pulp and paper concern in the province.

New Bureau of Mines Publication on Preparation and Uses of Tar

The issuance of Technical Paper 268, "Preparation and Uses of Tar and Its Simple Crude Derivatives," by W. W. Odell, fuel engineer, is announced by the United States Bureau of Mines. This paper discusses the uses to which some of the various tars are put and shows briefly the usual methods of working up tar into some of its simple or easily prepared derivatives. Although coal tars are given chief consideration, the properties and characteristics of water-gas tar are mentioned. This publication is not a handbook on tar distillation, but is published by the Bureau of Mines as a general treatise on the utilization of tar.

It may be obtained by addressing the Bureau of Mines, Washington, D. C.

New Power Map of Pennsylvania Shows Stations and Lines of Public Utilities

A map of Pennsylvania showing the location of the power stations and electrical transmission lines used by public utility companies has just been published by the United States Geological Survey, Department of the Interior.

This map is the second of a series now being published, that of New York having been recently issued. Two other maps are nearing completion, one covering New Hampshire and Vermont and the other covering Massachusetts, Connecticut and Rhode Island, and maps of Maine, New Jersey, Maryland and Delaware are also in preparation. These maps were prepared in collaboration with the power companies.

The two maps already published may be bought from the Director of the United States Geological Survey at Washington for 50 cents each.

Civil Service Openings for Junior Chemists

The United States Civil Service Commission invites attention to examinations to be held on May 24 and June 21 to fill positions of junior chemist in the departmental service at Washington, D. C., at entrance salaries ranging from $1,200 to $1,800 a year. These examinations require written tests in the examination room in addition to a rating on education, training and experience.

Further information regarding the pending examinations and application blanks may be obtained from the United States Civil Service Commission, Washington, D. C., or the secretary of the civil service board at the post office or custom house in any city.

U. S. Chamber of Commerce to Discuss Effect of European Conditions

"European Conditions and Their Effect on American Business" will be the main topic at the tenth annual meeting of the Chamber of Commerce of the United States, to be held in Washington, May 16 to 18. This announcement was made by the Chamber when it made public a tentative program for the meeting.

Because of the interest of business men throughout the country in the general subject it is predicted that the convention will be one of the largest ever held by the Chamber. More than 1,400 business organizations have been asked to send representatives and an attendance of from 4,000 to 5,000 business men is looked for.

New Course in Alloys at Wisconsin

Alloys and alloy steels will be studied intensively by about sixty students in the department of mechanical engineering of the college of engineering of the University of Wisconsin. This subject is included in a new course in metallography. An increasing demand from factories and shops for men who know the heat-treatment of metals and alloys as well as understanding the properties of alloys has brought about the introduction of this new study.

American Fertilizer Association Plans Meeting

The convention committee of the American Fertilizer Association is at work on the business and entertainment program for the twenty-ninth annual convention of the society, which is to be held at White Sulphur Springs, W. Va., the week beginning June 12.

Speakers will address the convention on subjects of importance to the fertilizer industry. Meeting headquarters will be established at the Greenbrier.

Alien Property Custodian Reports Activities

Alien Property Custodian Miller has transmitted to the Senate a detailed report of activities of his office since the declaration of war in the administration of trusts covering alien property, which includes chemical plants among some 33,000 active trusts under control of this agency. The report is in response to a resolution of inquiry by Senator King of Utah.

French Government May Co-operate in Development of Haber Process for Munitions

The Finance Committee of the French Chamber of Deputies is considering a bill relative to an agreement made on Nov. 11, 1919, by the Minister of Industrial Reconstruction and the Badische Anilin concerning the Haber process for synthetic ammonia. Amendments have been proposed by M. Loucheur aiming at the exploitation of the Haber process by a French commercial company, acting for account of the state in the form of an interested administration. The state would interfere directly as little as possible, and the intervention, if necessary, would be limited to the erection of the buildings necessary for the exploitation of the process.

It appeared from the discussion in the commission that the Haber process is to be instituted at the Toulouse powder mill, which will be equipped to produce daily the 100 tons of nitrogen which might eventually be necessary for the defense of the country.

Comparison of National Standards of Mass Made at Bureau of Standards

A comparison of certain platinum and platinum-iridium standards of the Bureau of Standards with the two national standards (kilogram No. 20 and kilogram No. 4) was completed during March and represents the most elaborate work of the kind that has been done by the bureau in many years.

One of the most gratifying features of the work is the complete agreement of the results based on the two national standards, notwithstanding the fact that one of them has been used several times, while the other has not been employed for actual weighing since it was received from the International Bureau of Weights and Measures in 1889.

About an equal number of weighings was made in determining the actual values of some of the gold-plated bronze standards. The computation of these results is not entirely complete, but it is evident that they will not be quite so accurate.

Personal

HARRY EASTWOOD, formerly with the American Radiator Co., Kansas City plant, is now research chemist for the Cook Paint & Varnish Co., North Kansas City, Mo.

E. E. KIMBLE and A. H. OTIS, president and sales manager, respectively, of the Kimble Glass Co., Vineland, N. J., sailed April 11 on the Aquitania to obtain first-hand information on conditions in the technical glass industry of France, Germany, Italy, Czechoslovakia, Switzerland, England and Scotland.

JOHN C. MILLER, sales manager of the Oklahoma Producing & Refining Corporation, Tulsa, Okla., has resigned. He will be succeeded by D. L. GILLAND, heretofore head of the distributing division of the company.

W. C. PETERSON, metallurgist engineer for the Atlas Crucible Steel Co., resigned April 1, to accept the position of manager of the alloy steel division of the Electric Alloy Steel Co., Youngstown, Ohio. Prior to the position which Mr. Peterson held with the Atlas Crucible Steel Co. he spent 12 years with the Packard Motor Car Co. as supervisor of materials in charge of metallurgical laboratories, heat-treating departments, etc.

C. E. POTTS, who recently resigned as superintendent of the sheet mills of the Inland Steel Co., Indiana Harbor, Ind., owing to ill health, will take up a residence at Los Angeles, Cal.

H. E. RICE, formerly with the R. R. Donnelley & Sons Co., is now in charge of research and development work for the American Printing Ink Co., Chicago, Ill.

R. L. SHEPARD, formerly research engineer for the Solvay Process Co. of Detroit, is now in charge of the die-casting department of the Shepard Art Metal Co., Detroit, Mich.

Dr. S. E. SHEPPARD, chief of the research laboratory of the Eastman Kodak Co., Rochester, N. Y., recently addressed the local section of the American Chemical Society on "Gelatine in the Photographic Process."

JOHN TOMEC, president of the Thac Industrial Products Corporation, Trenton, N. J., left recently for an extended trip to England, France, Germany and Austria.

PERCY WEDLAKE, formerly with the Washington Steel & Ordnance Co., Washington, D. C., is now with the Wilson-Maeulen Co., New York.

E. J. WINTER, formerly chief engineer of the American Cyanamid Co. and more recently the consulting engineer of the United States Food Products Corporation, of Peoria, Ill., is now associated with Bonn & Co., of New York.

Obituary

Dr. ANDREW MCWILLIAM, a well-known metallurgist and formerly professor of metallurgy in Sheffield University, died at Sheffield on April 5. He had had 24 years' association with the city when, in 1911, he accepted the appointment of head metallurgical adviser to the Government of India. Before his departure for India he was given the degree of doctor of metallurgy for his researches into the metallurgy of steel. For many years he was a most familiar figure at the Iron and Steel Institute meetings, and his numerous papers were always of a practical and suggestive character, and most welcome contributions. He was born in 1867 and educated at Glasgow and the Royal School of Mines, London, where he obtained a first-class scholarship. At one time he was chemist to the Martino Steel Co., and then for 2 years lecturer in metallurgy to the Staffordshire County Council. His principal writings are a book on "General Foundry Practice" and technical papers on "Elimination of Silicon in Acid Open Hearth," "Heat-Treatment of Bessemer Steels" and several on the properties of heat-treated alloy steels.

Prof. EMIL HEYN died at his home in Berlin-Dahlem, March 1. He was born at Annaberg, Erzgebirge, Saxony, in 1867, and was educated at Freiberg. After his college days he spent some time with the Krupp works in Essen, and with the Hoerder Verein (now the Phœnix Co.) of Hoerde, Westphalia. Later he became a member of the faculty of the Royal Machine Construction and Foundry School in Gleiwitz, Silesia, and in 1898 he was called to the Royal Institute for Testing Materials at Lichterfelde, acting as assistant director from 1904 to 1914. Since 1901 he had been professor of mechanical engineering, foundry practice and strength of materials at Charlottenburg Technical Hochschule. He had been president of the German Metallurgical Society since 1918, and in 1921 also assumed the position of director of the Kaiser Wilhelm Institute for Metallurgical Research at Neubabelsberg, near Berlin. Prof. Heyn's published studies have naturally followed the lines of strength of metallic materials as affected by their composition and structure. He was early attracted by the possibilities of metallography, and much of his work was done along these lines. He developed an etching reagent for macroscopic examination of steel; he upheld the idea that there were two iron: carbon equilibrium diagrams, stable and metastable; he called attention to the peculiar physical properties of steel midway between troostite and sorbite, and proposed the name Osmondite for this structure; and he was a stout opponent of the amorphous metal hypothesis. In the non-ferrous field his work was no less important, resulting in many papers on copper and aluminum alloy systems and bearing metals. He also gave much attention to the problem of corrosion. A short elementary book on metallography is from his pen; he also edited the monumental Marten's Handbook of Materials. For several years, however, almost his entire attention had been devoted to the direction of the institutions of which he was the head.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

The Rise in Wholesale Prices

Wholesale prices since the beginning of 1922 have shown a steady and appreciable increase. The index numbers of the Bureau of Labor Statistics, recently announced for the month of March, indicate a net rise of 1 point, or approximately two-thirds of 1 per cent, since Feb. 28. Of the 327 commodities, or price series, for which data were obtained, increases were found to have occurred for 104 commodities and decreases for 83 commodities. In the case of 140 no change in the average prices was reported.

The index numbers of wholesale prices by groups of commodities have been as follows during the last 4 months:

INDEX NUMBERS OF WHOLESALE PRICES, BY GROUPS OF COMMODITIES
(1913=100)

	1921 December	1922 January	1922 February	1922 March
Farm products	113	116	126	128
Foodstuffs	139	134	138	138
Cloths and clothing	185	183	183	182
Fuel and lighting	187	183	183	183
Metals and metal products	119	117	115	114
Building materials	203	202	202	202
Chemicals and drugs	161	159	159	159
Housefurnishing goods	218	214	213	213
Miscellaneous	148	146	150	153
All commodities	149	148	151	152

Farm products again showed an increase, due to advances in grain, hay, cattle, hogs, sheep and poultry. The increase in this group over the February level was approximately 1½ per cent. Food, fuel, building materials, chemicals and housefurnishing goods showed no change in the general price level. In the two groups of cloths and clothing and metals and metal products prices in March averaged somewhat lower than in February. On the other hand, the group of miscellaneous commodities, including, among others, such important articles as cottonseed meal and oil, linseed meal, slaughterhouse tankage, and a number of vegetable oils largely used for industrial purposes showed an increase of 2 per cent.

Specifications for Petroleum Products

The interdepartmental petroleum specifications committee has adopted a set of specifications for the use of the various government departments and independent establishments. These specifications, corrected to March 1, 1922, are now available as Technical Paper 305 of the Bureau of Mines. This publication supersedes the earlier publications of the committee, which has worked on the subject during the war period and since that time. Specifications are given for gasoline, naphthas, illuminating oils, fuel oils, lubricants, greases and a wide variety of similar petroleum products. The methods for testing which are to be observed under these specifications will be available shortly as Technical Paper 298 of the bureau. This latter paper, is, however, not yet printed.

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

This week	158.27
Last week	158.81
April, 1917	207
April, 1918 (high)	286
April, 1920	261
April, 1921 (low)	140

Practically no change was noted in the index number during the past week. Of the six commodities for which price changes were noted, four—viz., caustic soda, caustic potash, barium chloride and linseed oil—showed slightly higher prices and two—viz., crude potassium carbonate and cottonseed oil— showed decreases. The importance of the weighting for cottonseed oil was sufficient to more than compensate for the small increases in the other commodities.

The Effect of Tariff Protection on British Chemical Prices

In order to demonstrate any possible effect on British chemical prices of the so-called safeguarding of industries act, the *Times Trade Supplement* of London has taken a dozen chemicals which are entirely or chiefly manufactured in Great Britain and compared them with a similar number which are solely or largely imported.

These compilations, in shillings and pence, and the author's conclusions were as follows:

Chemicals (British)	Value Oct. 1, 1921	Value April 1, 1922
Acetone	85/0 cwt	75/0 cwt.
Aspirin	3/2 lb.	2/10 lb.
Benzoic acid	2/5 lb.	1/6 lb.
Beta naphthol	3/6 lb.	2/6 lb.
Calcium lactate	2/6 lb.	2/0 lb.
Formaldehyde	95/0 cwt.	74/0 cwt.
Formic acid	65/0 cwt.	60/0 cwt.
Methyl salicylate	2/9 lb.	2/4 lb.
Salicylic acid	1/6 lb.	1/4 lb.
Sodium hyposulphite	25/0 cwt.	19/6 cwt.
Salol	2/8 lb.	2/0 lb.

Chemicals (imported)	Value Oct. 1, 1921	Value April 1, 1922
Amidopyrin	21/0 lb.	18/0 lb.
Barbitone	12/0 lb.	11/0 lb.
Chloral hydrate	5/6 lb.	5/0 lb.
Guaiacol carbonate	12/6 lb.	9/6 lb.
Hexamethylenetetramine	4/3 lb.	3/0 lb.
Lithium carbonate	12/0 lb.	10/6 lb.
Paraldehyde	2/0 lb.	1/4 lb.
Phenacetine	6/6 lb.	5/3 lb.
Phenazone	8/0 lb.	7/6 lb.
Phenolphthalein	4/6 lb.	3/3 lb.
Potassium permanganate	1/0 lb.	–/9 lb.
Resorcin	8/3 lb.	7/3 lb.

"In order to arrive at a definite ratio of values it is convenient to consider each item as a unit and total the four columns. Thus treated, the British chemicals show values of £14 10s. 10d. (in October) and £12 5s. (in April), and the imported chemicals £4 17s. 6d. (in October) and £4 2s. 4d. (in April). By coincidence the percentage of difference is almost identical, and the average decrease in value of all the chemicals included is over 15 per cent. In other words, the act has not led to a general increase in price to the consumer of either British or foreign chemicals, despite the 33⅓ per cent duty and the prophecies to the contrary."

German Dye Prices and Dividends

According to a recent dispatch from Frankfort-on-the-Main to the New York *Journal of Commerce*, German manufacturers have announced a general increase in the prices of their products. The new quotations are said to be 40 to 50 per cent higher than the price schedule which is now superseded.

A later radio dispatch from the same source reports that the great dye combine (Interessen Gemeinschaft) earned a dividend of 30 per cent on its capital stock during the fiscal year 1921, as compared with 20 per cent in the preceding year.

Allied Chemical & Dye Corporation Reports Better Business Conditions

Although there was a marked fall in the earnings of the Allied Chemical & Dye Corporation in 1921, the recent annual report indicates that the corporation is in a stronger financial position and since the beginning of 1922 has enjoyed a much improved demand for its products.

The reduction in business due to the general depression is shown by the considerably lower income. After charges, inventory adjustments, federal taxes and preferred dividends, the net income was $7,646,909, equivalent to $2.27 a share on the outstanding common stock. In 1920 the income was $16,179,939, or $6.33 a share. Inventory adjustments in 1921 were $3,940,557, as compared with $10,226,688 for the previous year. However, the inventory on Dec. 31, 1921, stood at $33,434,653 and on the corresponding date in 1920 was $45,602,875.

Dr. W. H. Nichols, chairman of the board, pointed out in his letter to stockholders that the most important technical development in 1921 was the successful production on a commercial scale of synthetic ammonia at the nitrogen-fixation plant, Syracuse, N. Y. This plant, the only one of its kind in the United States, has been running at full capacity since it was completed last fall.

U. S. Industrial Alcohol Reports Deficit

The U. S. Industrial Alcohol Co., for the first time in its history, showed a net loss in 1921. This amounted to $572,047, after charges, depreciation and inventory adjustment. During the previous year the company had a net income of $3,339,499 and paid a dividend of $11.63 on its common stock.

The record of the company's earnings and dividends for the past 11 years is given in the following table:

Year Ended Dec. 31	Operating Income	Net Income	Amount Earned on Common Stock
1911	$1,308,399	$ 902,745	$2.01
1912	1,437,522	1,021,751	2.51
1913	1,006,774	652,358	0.97
1914	1,069,602	653,264	0.97
1915	2,724,607	2,172,013	7.30
1916	6,727,043	4,756,025	18.06
1917	12,511,277	6,980,420	27.33
1918	14,073,102	6,621,309	25.83
1919	4,426,265	2,834,858	10.06
1920	5,102,831	3,339,499	11.63
1921	82,638*	572,047*	.....

*Loss.

The New York Market

New York, April 24, 1922.

Leading producers report a steady call for the more important commodities, and shipment prices have maintained their former strength throughout the week. The most important feature of the market was the continued rise of barium chloride and yellow prussiate of potash. Inquiries from Italy and other European countries for solid caustic soda are keeping the export market for that commodity in a very firm position and the present tendency of alkali prices is upward. The recent rise in citric acid has been firmly maintained. Cyanide of soda has been somewhat neglected and prices showed a slight decline both for foreign and domestic material. Cream of tartar has displayed a stronger tone and the market recorded an advance for the week. The general list of products so far this month has shown every tendency to remain firm and leading factors have interpreted this as an approach to better business conditions.

General Chemicals

Acetic Acid.—There has been a better demand since the first of the month for this material. Producers offer the 28 per cent at $2.35 per 100 lb. in barrels. Large orders could probably be purchased down to $2.25. The 56 per cent has sold at 5c. per lb., and the glacial 99½ per cent sold at 9c. per lb.

Barium Chloride.—This material continued exceptionally strong throughout the entire week and quotations were around $100 per ton for spot goods in very limited quantities. This product has recorded a 100 per cent advance within the past few months. May-June shipment was held at $90 per ton. All other barium products have shown additional strength in sympathy with the chloride.

Bleaching Powder.—Domestic bleach is moving quietly at $1.60 per 100 lb. in large drums, f.o.b. works. The imported is quoted at $1.70 per 100 lb. dock. The demand is rather slow, with real competition for any passing business.

Borax.—Contracts for large quantities are held at 5¼c. per lb. in bags, 5½@5¾c. in barrels and 6c. per lb. in kegs. Small lots on the spot market command higher prices.

Boric Acid.—Round lots in bags are moving at 11c. per lb. and at 11½c. in barrels. Kegs are held around 12c. per lb. Small lots command a premium of ¼@½c. per lb. above these prices.

Caustic Potash.—Large importers report a moderate demand for the 88-92 per cent and reported several transactions at 5¾@6c. per lb. Shipment material is not attracting very much attention, as prices are in most cases above spot material.

Caustic Soda.—Export inquiries continue to reach the market and additional sales to Italy were recorded at $3.65 @$3.70 per 100 lb. Dealers are holding resale lots at $3.75 per 100 lb.

Cyanide of Soda.—Imported and domestic goods are a shade easier under a somewhat neglected buying condition. Sellers of imported offer spot goods at 22@24c. per lb., depending on strength. Domestic material is held at 25c. per lb.

Nitrite of Soda.—The market appears rather firm and several transactions were recorded at 8¾@9c. per lb. The general range is 8¾@9¼c. per lb., depending upon seller and quantity. Consumers are not buying any more than actual wants.

Prussiate of Potash.—There has been a pronounced scarcity in the yellow material. Spot offerings were exceedingly limited and dealers were asking 28c. per lb. The red variety still continues very scarce, with sellers asking 75c. per lb. for shipment.

Coal-Tar Products

The only outstanding feature in this market during the past week was the strength displayed by phenol. Resale lots are very scarce and firmly maintained. Benzene still continues in a very strong condition and little is obtainable on spot because of the steady absorption of deliveries on contracts to consumers. The recent reduction in the price of phthalic anhydride is bringing out a better demand and business has shown a noticeable improvement. Cresylic acid is firm at the recent advance.

Aniline Oil.—First hands were quoting 16c. per lb. and reported sales consumated at this figure. The demand has not been any too brisk and it was intimated that shading could be done on firm business.

Beta Naphthol.—There has been a better inquiry noted for this product and producers stated that they were getting 26@27c. per lb., depending on quantity. The sublimed is unchanged at 60c. per lb.

Acid.—Some small lot orders have been recorded among first hands. The lowest price heard was 85c. per lb., with the range up to $1, depending upon quantity. Demand is not very encouraging.

Phenol.—There has been no departure from the firm position of this crude. Second hands stated that it is doubtful if better than 12½c. per lb. could be done, while 13c. was being asked in several directions. Leading producers quoted the prime white crystals, U.S.P., at 15@17c. per lb.

Sulphanilic Acid.—Leading sellers are holding the market at 24@26c. per lb., but might shade these figures on firm business, owing to the slow movement. Sales are only of a light routine nature.

Naphthaline.—There were still a few consuming inquiries recorded during the week, but the general movement is rather quiet and large sellers are very much disappointed with the results of the season. Leading producers are unchanged in their recent prices.

The Chicago Market

CHICAGO, Ill., April 20, 1922.

Little change was to be noted in the general chemical market during the past week. Business continued fairly active and factors reported a satisfactory volume of small or medium-sized orders. Large buyers are still apparently holding off and are taking supplies for immediate consumption only. Practically all prices were firm and first hands were in control of the market, which is generally regarded as a healthy sign. Imported chemicals continue to advance in price and are becoming scarce.

General Chemicals

The alkali market was firm and stocks were reported to be moving fairly well in small lots. Solid *caustic soda* was quoted at $3.75@$4 per 100 lb. and the ground at $4.35@$4.50. *Caustic potash* is very firm and most sellers have advanced their price on the 88-92 per cent material to 7c., although it was reported that a few small lots could be had at 6¾c. *Soda ash* continued to move in the regular channels at $2.30 per 100 lb. for small lots in cooperage.

Alums were apparently in a firm position, but no transactions of consequence were reported. *Ammonia alum* was quiet at 4½@5c. per lb. for the ground. *Potash alum* was in some demand and the lumps could be bought at 5½c. for the U.S.P. or 4½c. for the technical. *Powdered potash alum* was in fair demand from the photographic trade and supplies were available at 5½@6½c., according to the quantity and the seller. Barium compounds were in an exceptionally firm position and prices showed a considerable advance. *Barium chloride* was very difficult to locate and the best offer noted was for shipment from the East at $90 per ton. *Copper sulphate* was in active demand and prices were firm at 6@6¼c. per lb. With warm weather in sight there was some pressure to sell *bleach*, which could be had at 2¾@3c. per lb. White *arsenic* is a little easier and supplies could be had at around 7½c. per lb. *Furfural* is still available at 50c. per lb. in single-drum lots. *Carbon tetrachloride* moved in a routine way and was unchanged at 10½@11c. per lb. Nothing new developed in the *glycerine* market and refiners continued to offer c.p. material at 16½c. per lb. bulk basis.

Potash bichromate was quiet and unchanged at 11¾@13c. per lb. *Soda bichromate* was in a similar position and was available at 9@9½c. per lb. A small sale of *red prussiate of potash* at 90c. per lb. was reported early in the week. *Yellow prussiate of potash* continued to move well at 32@35c. per lb. *Hypo* was in a somewhat better demand and was unchanged at $3.95 per 100 lb. for the pea crystals in barrels.

Linseed Oil—Naval Stores

Prominent factors in *linseed oil* reported a good movement in consuming channels. Prices were a little higher, with today's market on the boiled oil in 5-drum lots at 88c. per gal. and similar quantities of the raw at 86c.

Turpentine, like linseed oil, was reported to be moving in a satisfactory volume to the paint trade. Today's market on 5-drum lots was 83c. per gal., which represented a small decline. *Rosin* was in fair demand, and the "G" grade in less than carlots could be had at $6.35 per 280 lb.

The Iron and Steel Market

PITTSBURGH, April 21, 1922.

Strikes in the Connellsville and Lower Connellsville region have spread somewhat farther in the past week, but the tide appears now to have become stationary. Production of coal in the region as a whole is probably at not over one-third the rate in March, shipments of coal being decreased in greater ratio and production of coke in the region in somewhat less ratio. Of the strikes produced in non-union coal fields by the United Mine Workers, those in the Connellsville region are by far the most important. In many districts, according to the latest report of the Geological Survey, the demand for coal is insufficient to give the mines as full employment as labor conditions would admit.

By various means the iron and steel producers have tempered the effects of the Connellsville strikes, so that production is not restricted in full proportion to the amount of striking. There has been some additional drawing upon coal districts in position to produce freely, while there is some drawing upon stocks of coal.

Even to this date the influence of the Connellsville strikes has been more marked in preventing resumption of mills and furnaces than in restricting operations that were in progress April 1, whereby the production of steel is probably at a somewhat greater rate this week than on the last day of March, when steel ingot production was proceeding at the rate of 35,000,000 or 36,000 000 tons a year, against a rate of about 30,000,000 tons March 1 and an average rate of slightly under 20,000,000 tons in December.

Changed Character of Buying

The whole steel market is largely under the influence of the coal strike, in a double manner. Conservative and far-sighted buyers purchased liberally in February and March and undoubtedly accumulated stocks. Such buyers are not so conspicuous in the market now, while another class of buying has developed, on the part of consumers and distributors who appear decidedly frightened. The producers do not look with much favor upon buying of this sort, having some doubt whether the material will be entirely acceptable to the inquirers when delivered. The mills have learned to distinguish between the buyer who is attracted by a low price and the buyer who is attracted by an advanced price.

Inasmuch as the coal strike was expected for a year or so and serious efforts were made to insure against its possible effects, a quite erroneous view of the situation would be obtained by assuming that the strike, now that it has begun, has produced really important consequences. It is quite possible that serious consequences in markets generally would have followed had the strike suddenly been called off March 31. The steel situation appears stronger by reason of the strike, but perhaps it had need of some stiffening influence at this time.

Finished steel prices are being quite firmly maintained. This situation may be due to the coal strike, as is assumed in many quarters, or it may be due to mills having had fairly large sales and being disposed to stand their ground simply because they are fortified by back-log business. If so, the phenomenon is a familiar one.

Bars, shapes and plates are quite rigidly maintained at 1.50c., concessions from this figure being unusual if not entirely absent. Regular list prices on tubular goods are very well maintained, concessions having been dwindling for about 6 weeks past. Tin plate is reported quite firm at the official or regular price of $4.75. Sheets are held at prices as recently advanced $3 a ton. Hoops and bands are up $2 a ton, to 2c. In nails the independents maintain their recent advance to $2.50, while the Steel Corporation's price remains $2.40.

Pig Iron Higher

While the merchant furnaces may not have been definitely withdrawing as sellers, they have presented much the appearance of doing so, and quotable prices have advanced by an average of fully $2 a ton in the past fortnight. The valley market now stands at $21 for bessemer, $20 for basic and $21 for foundry, these being minimum prices, with some doubt as to whether any large purchases could be made at these figures. In bessemer the advance over the price April 1 is $1.50, while basic and foundry are up $2. Prices may work up still farther, as they are even now hardly up to what merchant furnaces assert is their cost. If Lake Superior ore prices for the 1922 season are developed in the near future, they will doubtless be in relation to these new prices for pig iron, in which case there would not be the reduction of about $1 a ton from the 1921 schedule that was being predicted 3 months and more ago.

Connellsville coke is not quotable as presenting regular market prices. The furnaces state they could not afford to pay advanced prices, while the offerings are only of extremely small lots, not enough to be worth while to a blast furnace even if the price were satisfactory. In foundry coke the demand is largely withdrawn, foundries generally having stocked in the past couple of months.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.	..... –	$0 38 – $0 40

Potassium prussiate, yellow	lb.	.28 – .28½	.28¾ – .29
Rochelle salts (see sodium potas. tartrate)		..... –	..... – .....
Salammoniac, white, granular	lb.	.07 – .07½	.07½ – .08
Salammoniac, gray, granular	lb.	.07½ – .07¾	.08 – .08¼
Salsoda	100 lb.	1.45 – 1.55	1.60 – 1.85
Salt cake (bulk)	ton	18.00 –20.00	..... – .....
Soda ash, light	100 lb.	1.80 – 2.00	2.05 – 2.60
Soda ash, dense	100 lb.	1.85 – 1.95	2.00 – 2.50
Sodium acetate	lb.	.04½ – .04½	.04¾ – .05
Sodium bicarbonate	100 lb.	1.80 – 1.90	1.95 – 2.40
Sodium bichromate	lb.	.07½ – .07¾	.08 – .08¾
Sodium bisulphate (nitre cake)	ton	4.50 – 4.60	4.65 – 5.50
Sodium bisulphite powdered, U.S.P.	lb.	.04¼ – .04½	.04¾ – .05¼
Sodium chlorate	lb.	.06½ – .07	.07¼ – .07¾
Sodium chloride	long ton	12.00 –13.00	..... – .....
Sodium cyanide	lb.	.22 – .23	.23½ – .25
Sodium fluoride	lb.	.09½ – .10	.10¼ – .10½
Sodium hydroxide (caustic soda)	100 lb.	3.70 – 3.75	3.80 – 4.25
Sodium hyposulphite	lb.	.03 – .03¼	.03½ – .03¾
Sodium nitrite	lb.	.08¾ – .09	.09½ – .09¼
Sodium peroxide, powdered	lb.	.28 – .30	.31 – .35
Sodium phosphate, dibasic	lb.	.03¾ – .04	.04¼ – .04½
Sodium potassium tartrate (Rochelle salts)	lb.	..... –	.18 – .21
Sodium prussiate, yellow	lb.	.16½ – .16¾	.17 – .17¼
Sodium silicate, solution (40 deg.)	100 lb.	.85 – 1.00	1.05 – 1.15
Sodium silicate, solution (60 deg.)	100 lb.	2.35 – 2.50	2.55 – 2.90
Sodium sulphate, crystals (glaubers salt)	100 lbs.	.85 – 1.00	1.10 – 1.50
Sodium sulphide, fused, 60-62 per cent (conc.)	lb.	.04¼ – .04½	.04¾ – .05½
Sodium sulphite, crystals	lb.	.03½ – .03⅝	.03¾ – .04¼
Strontium nitrate, powdered	lb.	.09½ – .10	.10¼ – .12
Sulphur chloride, yellow	lb.	.04½ – .05	.05¼ – .06
Sulphur, crude	ton	18.00 –20.00	..... – .....
Sulphur dioxide, liquid, cylinders extra	lb.	.08 – .08½	.09 – .10
Sulphur (sublimed), flour	100 lb.	..... –	2.25 – 3.10
Sulphur, roll (brimstone)	100 lb.	..... –	2.00 – 2.75
Talc—imported	ton	30 00 –40 00	..... – .....
Talc—domestic powdered	ton	18.00 –25 00	..... – .....
Tin bichloride	lb.	.09 – .09¼	.09½ – .10
Tin oxide	lb.	..... –	.37 – .38
Zinc carbonate	lb.	.14 – .14½	.14¾ – .15½
Zinc chloride, gran.	lb.	.05½ – .06	.06¼ – .06¾
Zinc cyanide	lb.	.42 – .44	.45 – .47
Zinc oxide, XX	lb.	.07½ – .08	.08¼ – .08½
Zinc sulphate	100 lb.	2.75 – 3.00	3.05 – 3.30

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.30 — .31
Aniline oil, drums extra	lb.	.16 — .16½
Aniline salts	lb.	.24 — .26
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.25 — 1.30
Benzidine, base	lb.	.85 — .9
Benzidine sulphate	lb.	.75 — .8
Benzoic acid, U.S.P.	lb.	.60 — .6
Benzoate of soda, U.S.P.	lb.	.55 — .57
Benzene, pure, water-white, in drums (100 gal.)	gal.	.29 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.27 — .32
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech.	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.60 — .65
Beta-naphthol, tech	lb.	.26 — .28
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97–99%, straw color, in drums	gal.	.53 — .55
Cresylic acid, 95-97%, dark, in drums	gal.	.48 — .50
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.80 — .85
Dimethylaniline	lb.	.38 — .40
Dinitrobenzene	lb.	.23 — .25
Dinitroclorbenzene	lb.	.23 — .25
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.33 — .35
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Dipnenylamne	lb.	.59 — .65
H-acid	lb.	.85 — 1.00
Meta-phenylenediamine	lb.	.90 — 1.00
Monochlorbenzene	lb.	.14 — .15
Monoethylaniline	lb.	1.10 — 1.25
Naphthalene crushed, in bbls.	lb.	.06 — .06¾
Naphthalene, flake	lb.	.06½ — .07
Naphthalene, balls	lb.	.08 — .08½
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17½
Ortho-amidophenol	lb.	2.60 — 2.75
Ortho-dichlor-benzene	lb.	.15 — .20
Ortho-nitro-phenol	lb.	.70 — .75
Ortho-nitro-toluene	lb.	.12 — .15
Ortho-toluidine	lb.	.16 — .20
Para-amidophenol, base	lb.	1.25 — 1.30
Para-amidophenol, HCl	lb.	1.30 — 1.35
Para-dichlorbenzene	lb.	.15 — .18
Paranitroaniline	lb.	.75 — .77
Para-nitrotoluene	lb.	.65 — .70
Para-phenylenediamine	lb.	1.50 — 1.55
Para-toluidine	lb.	1.05 — 1.15
Phthalic anhydride	lb.	.36 — .38

Phenol, U. S. P., drums	lb.	.12½	15
Pyridine	gal.	1.75 —	2.75
Resorcinol, technical	lb.	1.30 —	1.35
Resorcinol, pure	lb.	1.75 —	1.80
Salicylic acid, tech., in bbls	lb.	.24 —	.24½
Salicylic acid, U. S. P	lb.	.25 —	.26
Solvent naphtha, water-white, in drums, 100 gal	gal.	.25 —	.28
Solvent naphtha, crude, heavy, in drums, 100 gal	gal.	.10 —	.12
Sulphanilic acid, crude	lb.	.24 —	.26
Tolidine	lb.	1.20 —	1.30
Toluidine, mixed	lb.	.30 —	.35
Toluene, in tank cars	gal.	.25 —	.28
Toluene, in drums	gal.	.30 —	.35
Xylidines, drums, 100 gal	lb.	.40 —	.45
Xylene, pure, in drums	gal.	.40 —	.45
Xylene, pure, in tank cars	gal.	.45 —	....
Xylene, commercial, in drums, 100 gal	gal.	.33 —	.35
Xylene, commercial, in tank cars	gal.	.30 —	....

Waxes

Prices same as previous report.

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl	280 lb.	$5.25 —	5.30
Rosin E-I	280 lb.	5.35 —	5.40
Rosin K-N	280 lb.	5.45 —	6.55
Rosin W. G.-W. W	280 lb.	7.00 —	7.25
Wood rosin, bbl	280 lb.	6.25 —	.....
Spirits of turpentine	gal.	.85 —	.....
Wood turpentine, steam dist	gal.	.85 —	.....
Wood turpentine, dest. dist	gal.	.70 —	.70
Pine tar pitch, bbl	200 lb.	..... —	6.00
Tar, kiln burned, bbl. (500 lb.)	bbl.	..... —	9.50
Retort tar, bbl	500 lb.	—	9.00
Rosin oil, first run	gal.	.36 —	.....
Rosin oil, second run	gal.	.38 —	.....
Rosin oil, third run	gal.	.46 —	.....
Pine oil, steam dist., sp.gr., 0.930-0.940	gal.		$1.90
Pine oil, pure, dest. dist	gal.		1.50
Pine tar oil, ref., sp.gr. 1.025-1.035	gal.		.46
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o b. Jacksonville, Fla	gal.		.35
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.		.75
Pine tar, ref., thin, sp.gr., 1.080-1.960	gal.		.35
Turpentine, crude, sp. gr., 0.900-0.970	gal.		1.25
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990	gal.		.35
Pinewood creosote, ref	gal.		.52

Fertilizers

Quotations remain unchanged.

Crude Rubber

All prices same as report of April 19.

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls	lb.	$0.10 —	$0.10½
Castor oil, AA, in bbls	lb.	.11½ —	.12
China wood oil, in bbls	lb.	.13½ —	.13¾
Coconut oil, Ceylon grade, in bbls	lb.	.08¾ —	.09
Coconut oil, Cochin grade, in bbls	lb.	.09½ —	.09¾
Corn oil, crude, in bbls	lb.	.11 —	.11¼
Cottonseed oil, crude (f. o. b. mill)	lb.	.09¾ —	.10
Cottonseed oil, summer yellow	lb.	.12 —	.12½
Cottonseed oil, winter yellow	lb.	.13¼ —	.13
Linseed oil, raw, car lots (domestic)	gal.	.85 —	.86
Linseed oil, raw, tank cars (domestic)	gal.	.81 —	.82
Linseed oil, in 5-bbl lots (domestic)	gal.	.88 —	.89
Olive oil, denatured	gal.	1.12 —	1.15¼
Palm, Lagos	lb.	.07¾ —	.08
Palm, Niger	lb.	.05¾ —	.06
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.09½ —	.10
Peanut oil, refined, in bbls	lb.	.12½ —	.13
Rapeseed oil, refined in bbls	gal.	.83 —	.84
Rapeseed oil, blown, in bbls	gal.	.86 —	.87
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.10¾ —	....
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.09¾ —	....

FISH

Light pressed menhaden	gal.	$0.54 —	....
Yellow bleached menhaden	gal.	.57 —	....
White bleached menhaden	gal.	.56 —	....
Blown menhaden	gal.	.61 —	....

Miscellaneous Materials

Prices remain quotably unchanged.

Refractories

Quotations remain same as previous report.

Ferro-Alloys

All f.o.b. Works

Ferrocarbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y	net ton	$200.00 —	$225.00
Ferrochromium, per lb. of Cr contained, 6-8% carbon, carlots	lb.	.11 —	....
Ferrochromium, per lb. of Cr contained, 4-6% carbon, carlots	lb.	.11½ —	....
Ferromanganese, 76-80% Mn, domestic	gross ton	67.00 —	69.00
Spiegeleisen, 18-22% Mn	gross ton	30.00 —	35.00
Ferromolybdenum, 50-60% Mo, per lb. of Mo	lb.	2.00 —	2.25
Ferrosilicon, 10-15%	gross ton	38.00 —	40.00
Ferrosilicon, 50%	gross ton	54.00 —	55.00
Ferrosilicon, 75%	gross ton	115.00 —	120.00
Ferrotungsten, 70-80%, per lb. of contained W	lb.	.37 —	.50
Ferro-uranium, 35-50% of U, per lb. of U content	lb.	6.00 —	....
Ferrovanadium, 30-40% per lb. of contained V	lb.	3.55 —	3.75

Ores and Semi-finished Products

All f.o.b. New York, Unless Otherwise Stated

Bauxite, 52% Al content	net ton	$6.00 —	$12.00
Chrome ore, Calif. concentrates, 50% min. Cr_2O_3	ton	19.00 —	20.00
Chrome ore, 50% Cr_2O_3, f.o.b. Atlantic seaboard	ton	19.00 —	20.00
Coke, foundry, f.o.b. ovens	net ton	4.25 —	4.75
Coke, furnace, f.o.b. ovens	net ton	3.50 —	3.75
Fluorspar, gravel, f.o.b. mines, New Mexico	net ton	12.00 —	.....
Fluorspar, standard, domestic washed gravel Kentucky and Illinois mines	net ton	20.00 —	22.00
Ilmenite, 52% TiO_2, per lb. ore	lb.	.01½ —	.01½
Manganese ore, 50% Mn, c.i.f. Atlantic seaport	unit	.26½ —	27
Manganese ore, chemical (MnO_2)	net ton	60.00 —	65.00
Molybdenite, 85% MoS_2, per lb. of MoS_2, N. Y	lb.	40 —	.42
Monazite, per unit of ThO_2, c.i.f., Atlantic seaport	unit	27.00 —	.....
Pyrites, Spanish, fines, c.i.f., Atlantic seaport	unit	.12 —	.12
Pyrites, Spanish, furnace size, c.i.f. Atlantic seaport	unit	.13 —	.13
Pyrites, domestic, fines, f.o.b. mines, Ga	unit	.11 —	.12
Rutile, 95% TiO_2 per lb. ore	lb.	.12 —	.....
Tungsten, scheelite, 60% WO_3 and over, per unit of WO_3 (nominal)	unit	2.25 —	2.50
Tungsten, wolframite, 60% WO_3 and over, per unit of WO_3, N. Y. C	unit	2.50 —	2.75
Uranium ore (carnotite) per lb. of U_3O_8	lb.	1.25 —	1.75
Uranium oxide, 96% per lb. contained U_3O_8	lb.	2.25 —	2.50
Vanadium pentoxide, 99%	lb.	12.00 —	14.00
Vanadium ore, per lb. of V_2O_5 contained	lb.	1.00 —	....
Zircon, washed, iron free, f.o.b. Pablo, Florida	lb.	.04½ —	.13½

Non-Ferrous Metals

New York Markets

	Cents per Lb.
Copper, electrolytic	12.875
Aluminum, 98 to 99 per cent	19.00
Antimony, wholesale lots, Chinese and Japanese	5.00
Nickel, ordinary (ingot)	36.00
Nickel, electrolytic	39.00
Nickel, electrolytic, resale	30.00–33.00
Monel metal, shot and blocks	32.00
Monel metal, ingots	35.00
Monel metal, sheet bars	38.00
Tin, 5-ton lots, Straits	30.75
Lead, New York, spot	5.00–5.25
Lead, E. St. Louis, spot	4.95–4.975
Zinc, spot, New York	5.40
Zinc, spot, E. St. Louis	4.90

OTHER METALS

Silver (commercial)	oz.	$0.70
Cadmium	lb.	1.00–1.10
Bismuth (500 lb. lots)	lb.	2.00@2.10
Cobalt	lb.	3.00@3.25
Magnesium	lb.	1.15
Platinum	oz.	85.00@ 90.00
Iridium	oz.	160.00@170.00
Palladium	oz.	55.00@ 60.00
Mercury	75 lb.	51.00

OLD METALS—The following are the dealers' purchasing prices in cents per pound:

	New York Current
Copper, heavy and crucible	10.25@10.50
Copper, heavy and wire	10.00@10.25
Copper, light and bottoms	7.75@ 8.25
Lead, heavy	3.60@ 3.85
Lead, tea	3.00@ 3.25
Brass, heavy	4.50@ 4.75
Brass, light	4.00@ 4.25
No. 1 yellow brass turnings	4.00@ 4.25
Zinc	2.25@ 2.50

Structural Material

The following base prices per 100 lb. are for structural shapes 3 in. by ¼ in. and arger, and plates ¼ in and heavier, from jobbers' warehouses in the cities named:

	New York*	Chicago
Structural shapes	$2.48	$2.38
Soft steel bars	2.38	2.28
Soft steel bar shapes	2.38	2.28
Soft steel bands	2.98	2.88
Plates, ¼ to 1 in. thick	2.48	2.38

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

EUFAULA—The City Council will soon call for bids for the installation of a filtration plant in connection with the waterworks system. The Ludlow Engineering Co., Winston-Salem, N. C., is engineer.

Arkansas

FORT SMITH—The Twin City Glass Co., recently organized with a capital of $100,000, has acquired local property comprising about 4 acres of land and will commence the immediate erection of a new plant for the manufacture of bottles, jars and other glass products. The main building will be about 50 x 100 ft., and will be supplemented by a number of smaller structures. A 15-ton glass tank will be installed. Harry Hart is president.

California

SAN FRANCISCO—The Magnolia Metal Co., Pacific Bldg., has taken bids for the erection of a new 1-story plant at Bryant and Sterling Sts., to cost about $15,000. Work will be commenced at an early date. Dodge A. Reidy, Pacific Bldg., is architect.

ANTIOCH—The Paraffin Paper Box Co. is considering plans for the rebuilding of the portion of its plant destroyed by fire, April 5, with loss estimated at about $30,000.

Florida

BAGDAD—The Bagdad Land & Lumber Co. has acquired property in Escambia County, Ala., and has preliminary plans under way for the erection of a new pine tar and turpentine extraction plant.

Georgia

CONCORD—Fire, April 8, destroyed a portion of the fertilizer works of R. H. Strickland, with loss estimated at about $75,000, including section of feed milling plant and machinery in both structures.

Idaho

COEUR D'ALENE—Idaho Clays, Inc., recently organized, will hold in temporary abeyance the construction of its proposed new plant on property acquired on Twelfth St., between Indiana and Pennsylvania Aves., Hayden Lake district, to be used for the manufacture of pottery, tile and other burned clay products. It will be built at a later date. L. A. Spear is president.

Illinois

CHICAGO—The Globe Varnish Co., 5338 Justine St., has filed plans for the erection of a new 2-story plant, 75 x 100 ft., at 750-58 Loomis St., estimated to cost about $35,000.

Indiana

NEW ALBANY—The Interstate Public Service Co., Indianapolis, will commence the immediate enlargement of its gas plant here, to include the construction of a new 300,000 cu.ft. gas holder. It is expected to double the present capacity.

WHITING—Fire, April 14, destroyed a portion of the plant of the Standard Oil Co., with loss estimated at about $150,000, including a battery of stills, and other equipment.

INDIANAPOLIS—The Scoria Mfg. Co., operating at the former works of the Broad Ripple Fuel & Supply Co., has acquired a site at 63rd St. and the Monon Railroad for the erection of a new plant for the manufacture of hollow wall tile, cement blocks and kindred products. Plans will be prepared at an early date. The factory will be equipped for a daily output of 20,000 ft. of material, and is estimated to cost approximately $50,000. E. L. Selvage is president, and Charles T. Hornaday, vice-president and treasurer.

SEYMOUR—The Buhner Fertilizer Co. has tentative plans under consideration for the rebuilding of its plant, destroyed by fire, April 12, with loss estimated at $50,000, including equipment.

Kentucky

ASHLAND—The Ashland Fire Brick Co., Winchester Ave. and 7th St., will make a number of improvements in its plant, including the remodeling of certain departments. Additional equipment will be installed. E. H. Gartrell is general manager.

LOUISVILLE—The Peaslee-Gaulbert Co., 413 West Main St., manufacturer of varnishes, wood finishes, etc., has plans under way for extensions and additions in its plant on 15th St., to cost about $100,000. D. X. Murphy & Bro., Louisville Trust Bldg., are architects.

Louisiana

HAYNESVILLE—The Standard Oil Co. will make extensions in its local tankage and distributing plant, including seventy 55,000-bbl. capacity storage tanks and auxiliary equipment. Work will be commenced at once.

WASHINGTON — The Louisiana Concrete Products Co., recently organized with a capital of $60,000, has acquired a local site and has plans in preparation for the erection of a plant for the manufacture of cement roofing tile and kindred products. Extensions will be made in the initial works at a later date for departments for the manufacture of bricks, blocks and other specialties. A. D. Alderson, Alexandria, La., is president; H. H. Holloway, Amite, La., is engineer.

Maryland

EASTON—The New Brick & Tile Co., recently formed with a capital of $50,000, is completing plans and will soon break ground for the erection of a new local plant for the manufacture of brick, drain tile and other burned clay products. It is expected to have the works equipped and ready for operation some time in June. The company is headed by U. G. Ross, J. Fletcher Clark and Robert L. Kemp, all of Easton.

BALTIMORE—The Brooks Mexican Petroleum Co., 7 St. Paul St., has preliminary plans under way for the construction of a new oil storage and distributing plant on site in the Curtis Bay section, recently acquired. It will comprise a pier, tankage works, storage facilities for about 300,000 bbl., and auxiliary equipment, and is estimated to cost close to $500,000. The company has been organized lately under state laws. W. B. Brooks is vice-president and general manager.

BALTIMORE—The Lasco Co., 206 South Sharp St., manufacturer of shellac and kindred products, is planning for extensions in its plant at 1117 Bush St., and will install equipment to more than double the present capacity. L. A. Stabler is president.

BALTIMORE—The Baltimore Brick Co., Maryland Trust Bldg., is completing the rebuilding of its plant No. 13 at East Baltimore, recently destroyed by fire, and will install machinery at an early date.

BALTIMORE—The Miller-Nelson Co., Belair Road, near Park Ave., will construct a new addition, 50 x 50 ft., at its cement products plant, to be equipped for molding and other service, estimated to cost about $25,000.

Michigan

KALAMAZOO — The Kalamazoo Sanitary Mfg. Co., Factory St., has rejected all bids recently received for the erection of its proposed 2-story addition, 120 x 400 ft., and will hold the project in temporary abeyance. If is estimated to cost about $200,000, including equipment.

MARYSVILLE—The Morton Salt Co. is rushing work on the three new factory buildings now in course of erection, and plans to have the structures equipped and ready for operation at an early date.

ESSEXVILLE—The Aetna Portland Cement Co., 412 Union Trust Bldg., Detroit, will commence foundation work at once for the different buildings to comprise its new plant at Essexville. The main building will be 375 x 900 ft., to include grinding departments, coolers, etc.; three kilns will be constructed. The plant will have an initial output of about 3,000 bbl. of cement per day, and is estimated to cost in excess of $750,000. Franklin R. Johnson is president; and O. J. Lingeman, secretary.

IONIA—The Michigan Porcelain Tile Co., recently organized, has taken bids on a general contract and will soon break ground for the erection of its proposed local plant, 1-story, 120 x 160 ft., estimated to cost about $45,000. It will be equipped for the manufacture of tile and other burned clay products. Harry E. Kidder is general manager.

Mississippi

LUCEDALE—Allman Clark & Co. have plans under way for the erection of a new plant on local site, recently acquired, for the production of turpentine and other distilled products.

New York

RETSOF—The Retsof Mining Co. has plans nearing completion and will soon take bids for the construction of a local salt mining and manufacturing plant, to be 1- and 2-story, estimated to cost in excess of $500,000, including equipment.

OAKFIELD—The extensions to be erected at the local plant of the United States Gypsum Co., 1170 Broadway, New York, will consist of two new buildings, 50 x 600 ft., and 50 x 100 ft. The first noted will be equipped for the production of gypsum wallboard products and the other structure for the manufacture of roofing tile and kindred specialties. Work will be commenced at an early date.

Oklahoma

SAPULPA—The Sapulpa Refining Co. is planning for the rebuilding of the tankage department and other portions of its local plant, destroyed by fire, April 4, with loss reported in excess of $300,000, including equipment.

Pennsylvania

PHILADELPHIA—John Harrison, Jr., 21st and Race Sts., manufacturer of oil products, has awarded a contract to Barclay, White & Co., 1713 Sansom St., for the erection of a 1-story addition to his plant. Work will be commenced at once.

South Carolina

GAFFNEY—The McGraw Brick Co. is perfecting plans for the installation of new equipment at its plant for the manufacture of building tile and other burned clay products. The work will include the construction of a number of new kilns. It is proposed to develop an output of about 125 tons of tile per day, while the brick department will be arranged on a basis of 100,000 bricks per day. C. D. Meadows is secretary and general manager.

Tennessee

HARRIMAN—The Poland Mining Co., recently organized, has leased a portion of the local W. N. Poland, and will install a plant for the production of precious metals. Work will be commenced at an early date. Charles C. Jarvis heads the company; J. C. Williams is engineer.

Texas

MEXIA—The Texas-Mexia Refining Co., lately organized, will soon break ground for the construction of a new oil-refining plant on local site, with daily output of about 3,000 bbl. It is estimated to cost approximately $500,000, including machinery.

COLEMAN—The City Council will soon commence the installation of a new filtration plant at the municipal waterworks. R. V. Wood is secretary.

ROCKDALE—The Empire Fuel Corporation, Dallas, operating lignite properties near Rockdale, is planning for the erection of a fuel carbonization and briquetting plant, with byproduct works for the manufacture of chemicals, dyes and kindred products from raw lignite. The company has recently increased its capital from $1,000,000 to $5,000,000, to provide funds for the plant. Adam H. Davidson is chairman of the board and treasurer; Roy R. McKee is secretary.

West Virginia

CHARLESTON—The Libbey-Owens Sheet Glass Co., Nicholas Bldg., Toledo, O., will soon commence the erection of additions to its local plant, including improvements in the present structures, estimated to cost close to $200,000, including equipment.

Capital Increases, Etc.

THE NATIONAL PORTLAND CEMENT CO., Mount Pleasant, Mich., has filed notice of increase in capital from $2,000,000 to $61,400,000.

THE BROWN CO., Berlin, N. H., manufacturer of bleached sulphite pulp and paper, has arranged for a bond issue of $3,000,000, the proceeds to be used for general operations and financing.

THE HUDSON OIL CO. OF DELAWARE, 135 Broadway, New York, N. Y., has filed notice of increase in capital from $1,000,000 to $3,000,000.

THE LITTLE FALLS PAPER CO., Little Falls, N. Y., has filed notice of dissolution under state laws.

THE RED BIRD OIL CO., Barboursville, Ky., has filed notice of increase in capital to $50,000.

THE STANDARD MINING & CHEMICAL WORKS, 42 Broadway, New York, N. Y., has filed notice of increase in capital from $75,000 to $100,000.

A receiver has been appointed for the WESTERN PENNSYLVANIA OIL CO., Butler, Pa.

A petition in bankruptcy has been filed against the MURCOTT STEEL PRODUCTS CO., 776 Jamaica Ave., Brooklyn, N. Y.

THE UNION BAG & PAPER CO., Woolworth Bldg., New York, N. Y., has perfected plans for a bond issue to total $3,000,000, to be used for general operations, financing, etc.

Louis B. Wehle has been appointed receiver in bankruptcy for the ABORN STEEL CO., 22 Clark St., New York. The liabilities are said to be $100,000, and assets $75,000.

New Companies

THE NUDRO CO., Bayonne, N. J., has been incorporated with a capital of $500,000, to manufacture chemicals and chemical by-products. The incorporators are G. F. and Robert L. Eaton, 115 East 5th St., Bayonne.

THE LINCOLN OIL CO., Boston, Mass., has been incorporated with a capital of $50,000, to manufacture oil products. Joseph B. Shrago is president, and Charles Shrago, 51 McLellan St., Roxbury, Mass., treasurer.

H. C. COLLIER & SONS, INC., Binghamton, N. Y., has been incorporated with a capital of $100,000, to manufacture chemicals, paints and kindred products. The incorporators are H. C., C. E. and C. R. Collier, all of Binghamton. The company is represented by Merchants, Waite & Waite, Binghamton.

THE DAWHOO CHEMICAL CO., Charleston, S. C., has been chartered under state laws to manufacture chemicals and chemical by-products. The incorporators are J. P. Matthews and E. Risher, both of Charleston.

THE UNITED CHEMICAL CO., Dallas, Tex., has been incorporated with a capital of $30,000, to manufacture chemicals and affiliated products. The incorporators are William G. Carroll, G. T. and E. O. Cobb, both of Dallas.

THE EASTON FOUNDRY & MFG. CO., Easton, Pa., has been incorporated with a capital of $75,000, to manufacture iron, steel and other metal castings. Raymond Kiser, Easton, is treasurer.

THE STEVENS ZODIPHRENT PRODUCTS CO., New York, has been incorporated with a capital of $50,000, to manufacture soaps and kindred products. The incorporators are R. D. Elder, C. J. Wood and B. Clark, Jr. The company is represented by Fitch & Grant, 32 Nassau St., New York.

THE OKLAHOMA OIL CO., Columbus, O., has been incorporated under Delaware laws, with capital of $8,100,000, to manufacture petroleum products. The incorporators are J. M. Lee, H. A. Evans and M. C. McShane, all of Columbus. The company is represented by Boyce & Magee, Dover, Del.

ROBERT W. LINTON, INC., Pawtucket, R. I., has been incorporated with a capital of $60,000, to manufacture paper products. The incorporators are Walter C. Newell, Henry L. Burdick and Robert W. Linton, 750 York Ave., Pawtucket.

THE INDEPENDENT SHOPE BRICK CO., Waco, Tex., has been incorporated with a capital of $60,000, to manufacture brick, tile and other burned clay products. The incorporators are B. W., G. V. and George Willig, all of Waco.

THE ANNABELLE MFG. CO., Syracuse, N. Y., has been incorporated with a capital of $100,000, to manufacture chemicals, rubber products, etc. The incorporators are N. Vaeth, L. and G. Kallfelz, Syracuse. The company is represented by Shea & Crimmins, University Block, Syracuse.

THE AMERICAN SUPPLY CO., Miami, Fla., has been chartered under state laws to manufacture fertilizer products. Frederick C. Gomer, Miami, is president; Charles R. Graham, Goulds, Fla., vice-president; and W. K. Walton, Homestead, Fla., secretary.

THE ISCOLITE CORP., East Orange, N. J., has been incorporated with a capital of $200,000, to manufacture waterproofing materials. The incorporators are Albert R. Palmer, Leslie Reid and William H. O'Neill. The company is represented by the New Jersey Registration & Trust Co., 525 Main St., East Orange.

THE DU-RA ALUMINUM CO., Oklahoma City, Okla., has been incorporated with a capital of $5,000, to manufacture aluminum and other metal products. The incorporators are J. F. and D. B. Boettcher, and O. J. Logan, Oklahoma City.

THE LITTLE FALLS PAPER CO., New Windsor, Orange County, N. Y., has been incorporated with a capital of $250,000, to manufacture paper products. The incorporators are R. W. Spencer, S. L. Holden and L. J. White. The company is represented by Scott & Sneed, Newburgh, N. Y.

THE WILCO ASBESTOS MFG. CO., Brooklyn, N. Y., has been incorporated with a capital of $10,000, to manufacture asbestos products. The incorporators are I. Wilkes, J. and B. Cohen, Brooklyn. The company is represented by H. D. Levy, 808 Broadway, Brooklyn.

THE MEADE RUBBER CO., Stoughton, Mass., has been incorporated with a capital of $150,000, to manufacture rubber products. James Meade, Stoughton, is president and treasurer; Patrick H. Mahoney is vice-president.

THE SOUTHWEST CHEMICAL CO., Dallas, Tex., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. The incorporators are J. William Morrow, M. C. Harris and J. F. Harrington, all of Dallas.

THE PEERLESS CONCRETE BRICK MFG. CO., INC., Philadelphia, Pa., has been incorporated with a capital of $10,000, to manufacture cement brick and kindred products. J. B. McDevitt, 2004 North 25th St., Philadelphia, is treasurer.

THE SOUTHERN STATES OIL CORP., Dover, Del., has been incorporated under state laws with a capital of $20,000,000, to manufacture petroleum products. The company is represented by Boyce & Magee, Dover.

THE HIGH TENSION INSULATOR CORP., Ballston Spa, N. Y., has been incorporated with a capital of $50,000, to manufacture porcelain and other insulating products. The incorporators are R. H. Davidson, W. H. Namack and C. Branda. The company is represented by E. D. Eddy, Saratoga Springs, N. Y.

THE FORT DEARBORN DRUG & CHEMICAL CO., 225 North Michigan Ave., Chicago, Ill., has been incorporated with a capital of $5,000, to manufacture chemicals and by-products, drugs, etc. The incorporators are Leonard Kaufman, Victor P. Houston and M. S. Greenbaum.

THE UNITED STATES CHEMICAL TEST CO., New York, N. Y., has been incorporated with a capital of $5,000, to manufacture chemicals and chemical byproducts. The incorporators are F. Johnson, J. T. Fitzgerald and M. M. Klein. The company is represented by M. Eichner, 1545 Broadway, New York.

SANNER BROS., INC., Philadelphia, Pa., has been incorporated under Delaware laws with capital of $100,000, to manufacture oil products. The incorporators are Celestin Sanner, Jules A. Rominger and M. L. O'Neill, Philadephia. The company is represented by Amos A. Watson, Dover, Del.

THE NEILAN OIL & REFINING CO., Houston, Tex., has been incorporated with a capital of $150,000, to manufacture refined petroleum products. The incorporators are P. A. Neilan, M. H. Gubbels and J. J. Chadll, all of Houston.

THE WHALEBACK PRODUCTION CO., New York, N. Y., has been incorporated under Delaware laws with a capital of $500,000, to manufacture oil products. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

THE NITRAM PRODUCTS CO., Paterson, N. J., has been incorporated with a capital of $200,000, to manufacture ferro-alloys. The incorporators are James S. Cudlipp, Carl C. and Ernest Greiner, 230 East 18th St., Paterson.

THE BLAYNE LABORATORIES, INC., 1442 Majestic Bldg., Detroit, Mich., has been incorporated with a capital of $5,000, to manufacture chemical specialties. The incorporators are Walter H. Blome, Franklin S. Payne and E. H. Frye.

THE SAN MARCOS OIL CORP., New York, N. Y., has been incorporated with a capital of $50,000, to manufacture oil products. The incorporators are L. J. Lynch, F. A. Gill and D. T. Almond. The company is represented by W. F. Clare, 135 Broadway, New York.

THE CHAUTAUQUA PRODUCTS CO., Jamestown, N. Y., has been incorporated with a capital of $10,000, to manufacture rubber specialties. The incorporators are A. W. Jackson, F. M. Garfield and W. A. Stoeltzing. The company is represented by Mott & Ottaway, Jamestown.

THE MID-STATES TANNING CO., 2417 Smith Ave., Detroit, Mich., has been incorporated with a capital of $15,000, to manufacture leather products. The incorporators are James McAdoo, Jacob M. Feldstein and James D. May.

THE ORTEX OIL CO., Beaumont, Tex., has been incorporated with a capital of $50,000, to manufacture petroleum products. The incorporators are H. M. Higgins, E. L. Hall and O. H. Maschek, all of Beaumont.

THE PLASTIC PRODUCTS CO., New York, N. Y., has been incorporated with a capital of $10,000, to manufacture composition paper products. The incorporators are M. Baumann, L. Rothbart and M. Symington. The company is represented by E. L. Brooks, 176 Broadway, New York.

THE PAINT SPECIALTIES CORP. OF NEW JERSEY, Jersey City, N. J., has been incorporated with a capital of $15,000, to manufacture paints, varnishes, etc. The incorporators are John D. Craven, Walter J. Freund and George A. Wardell. The company is represented by Alfred K. Moe, 15 Exchange Place, Jersey City.

THE WOODISON-KELLEY CO., 7415 St. Aubin Ave., Detroit, Mich., has been incorporated with a capital of $20,000, to manufacture chemical compounds, pastes, and kindred specialties. The incorporators are E. J. and J. C. Woodison, and Alfred D. Kelley.

THE NEW YORK GUMMED PAPER CO., New York, N. Y., has been incorporated with a capital of $5,000, to manufacture paper products. The incorporators are E. D. and I. W. Ehrler, and A. F. Mayo. The company is represented by M. F. Miller, 350 Fulton St.

THE WOLVERINE CASTINGS CO., 405 East Ransom St., Kalamazoo, Mich., has been incorporated with a capital of $10,000, to manufacture iron and other metal castings. The incorporators are William and Edward Korman, and Joseph W. Stohrer, Kalamazoo.

Industrial Developments

OIL—The Vacuum Oil Co. has adopted a full-time operating schedule at its plant at Olean, N. Y., replacing a half-time basis operative for a number of weeks past. About 400 men are affected.

The India-Burma Oilfields Co., Rangoon, Burma, has opened its new oil-refining plant, recently completed, located about 15 miles from the city. The new refinery will run on a capacity basis for an indefinite period, using crude oil from the Yana and Padaupkin fields.

GLASS—The Hemingway Glass Co., Muncie, Ind., is increasing production at its plant, and expects to be on a close to normal basis at an early date.

The Owens Bottle Co., Toledo, O., has advanced production at its plants to about 80 per cent of capacity, and expects to increase the schedule at an early date. This same time a year ago the plants were running on a 25 per cent basis.

RUBBER — The Hydro-United Tire Co., Pottstown, Pa., has adopted a night shift at its plant, in addition to regular day production, under capacity operations.

The Miller Rubber Co., Akron, O., manufacturer of automobile tires, is planning to make further increases in production at an early date.

The Mason Tire & Rubber Co., Akron, O., is developing an expansion program providing for tire manufacture at practically double the regular output. It will be made effective at an early date.

CERAMIC— The Gill Clay Pot Co., Muncie, Ind., is increasing operations at its plant, giving employment to additional workers.

The Star Clay Co., Mertztown, Pa., has resumed production at its works, following a shut-down for some time past.

PAPER—The American Writing Paper Co., Holyoke, Mass., has advanced production about 20 per cent at its different mills in Connecticut and Massachusetts since the first of the year.

According to an official statement of the American Paper & Pulp Association, mills in the industry throughout the country are

now running on an average total of 75 per cent of capacity, following the worst conditions, for 24 months past, experienced in this line for a generation.

METALS—The Anaconda Copper Co. has placed its High Ore and Anaconda properties, two of the largest producers in the Butte, Mont., district, in service, following an extended shut-down. The company is increasing production at its plants to a point nearer normal far exceeding earlier estimates.

The Utah Copper Co., Salt Lake City, Utah, has reopened a portion of its properties, the largest in this section, following a shut-down for about a year past. The company has also resumed active production at its Magna, Utah, plant.

The Phelps-Dodge Co., New York, is operating at its Copper Queen smelting plant, Arizona, after a shut-down of about 10 months.

The Utah-Apex Mining Co., Salt Lake City, Utah, has resumed operations at its plant, following a curtailment for about a year past.

The Calumet & Hecla Co., Inc., has resumed operations at a portion of its copper properties at Calumet, Mich., following an extended shut-down. It is proposed to develop production to a point of about 2,000 tons a day by May 1, with the resumption of the reclamation plant not later than this date, providing a monthly output of about 1,500,000 lb. of refined copper.

CEMENT—The Kansas City Cement Co., Cement City, Mo., is increasing production at its local plant and has added about 150 men to the working force.

The Atlas Portland Cement Co. is increasing the output at its plant at Northampton, Pa., and is placing subsidiary departments in operation after period of curtailment, including the local bag factory.

Cement shipments from the Lehigh Valley district of Pennsylvania are now exceeding 100 cars a day. The mills have been stocking up with bituminous coal for a number of weeks past, and now have close to a 3 months' supply on hand.

TIN PLATE—The N. & G. Taylor Co. has resumed operations at the open-hearth and bar mill departments at its plant at Cumberland, Md. The black plate and tinning departments are now running at about 90 per cent of normal.

IRON AND STEEL—The Easton Steel Co. has resumed operations at full capacity at one of the blast furnaces at its mills at Pottstown, Pa.

The Otis Steel Co., Cleveland, O., has advanced production to a full capacity, 100 per cent basis, at its steel mills.

The Republic Iron & Steel Co. is making repairs to a second furnace at its Thomas, Ala., plant, and will place the unit in service about May 1.

The Sloss-Sheffield Steel & Iron Co. has blown in another furnace at its North Birmingham, Ala., works, and will soon blow in the furnace at its Philadelphia mill at Florence, Ala.

The United States Steel Corp. has blown in another blast furnace at its Gary, Ind., plant, making 17 furnaces in active production at this works.

New Publications

BAKING TECHNOLOGY is the title of "a journal of applied science in baking," published monthly by the American Bakers' Association, 1135 Fullerton Ave., Chicago. The first number was issued in January. It sets a high editorial and professional standard and will undoubtedly prove to be a strong factor in raising the technology of the baking industry.

THE NATIONAL RESEARCH COUNCIL has published Bull. 16, dated December, 1921, on "Research Laboratories in Industrial Establishments of the United States," including consulting research laboratories.

U. S. GEOLOGICAL SURVEY PUBLICATIONS: I: 14, Gold, Silver, Copper, Lead and Zinc in Montana in 1920, by C. N. Gerry (Mineral Resources of the U. S., 1920, Part I), published Dec. 17, 1921; I: 18, Gold, Silver, Copper, Lead and Zinc in Utah in 1920, by V. C. Heikes (Mineral Resources of the U. S., 1920, Part I), published Jan. 18, 1922; I: 19, Gold, Silver, Copper, Lead and Zinc in Nevada in 1920, by V. C. Heikes (Mineral Resources of the U. S., 1920, Part I), published Jan. 13, 1922; I: 20, Gold, Silver, Copper, Lead and Zinc in Arizona in 1920, by V. C. Heikes (Mineral Resources of the U. S., 1920, Part I), published Jan. 19, 1922; I: 21, Iron Ore, Pig Iron and Steel in 1920, by Ernest F. Burchard and Hubert W. Davis (Mineral Resources of the U. S., 1920, Part I), published Jan. 23, 1922; I: 22, Cobalt, Molybdenum, Nickel, Tantalum, Titanium, Tungsten, Radium, Uranium and Vanadium in 1920, by Frank L. Hess (Mineral Resources of the U. S., 1920, Part I), published Feb. 20, 1922; I: 28, Tin in 1919, by Adolph Knopf and Bertrand L. Johnson (Mineral Resources of the U. S., 1919, Part I), published Jan. 26, 1922; II: 2, Salt, Bromine and Calcium Chloride in 1920, by Ralph W. Stone (Mineral Resources of the U. S., 1920, Part II), published Feb. 21, 1922; II: 24, Talc and Soapstone in 1920, by Edward Sampson (Mineral Resources of the U. S., 1920, Part II), published Jan. 20, 1922; II: 25, Gems and Precious Stones in 1920, by B. H. Stoddard (Mineral Resources of the U. S., 1920, Part II), published Dec. 29, 1921; II: 26, Concrete Stone and Concrete Blocks in 1920, by R. W. Stone (Mineral Resources of the U. S., 1920, Part II), published Jan. 12, 1922; II: 27, Stone in 1920, by G. F. Loughlin and A. T. Coons (Mineral Resources of the U. S., 1920, Part II), published March 6, 1922; II: 28, Cement in 1920, by Ernest F. Burchard (Mineral Resources of the U. S., 1920, Part II), published March 7, 1922.

NEW BUREAU OF STANDARDS PUBLICATIONS: Sci. Paper 425, Characteristic Soft X-Rays From Arcs in Gases and Vapors, by F. L. Mohler and Paul D. Foote; Sci. Paper 426, Thermal Expansion of Nickel, Monel Metal, Stellite, Stainless Steel and Aluminum, by Wilmer H. Souder and Peter Hidnert; Sci. Paper 429, Note on the Preparation of Mannose, by E. P. Clark; Tech. Paper 200, An Investigation of Oxyacetylene Welding and Cutting Blow-Pipes, With Especial Reference to Their Design, Safety and Economy in Operation, by Robert S. Johnston; Tech. Paper 203, Influence of Phosphorus Upon the Microstructure and Hardness of Low-Carbon, Open-Hearth Steels, by Edward C. Groesbeck; Tech. Paper 294, Cutting Fluids, by Eugene C. Bingham; Tech. Paper 205, Tensile Properties of Some Structural Alloy Steels at High Temperatures, by H. J. French; Tech. Paper 296, Effect of Heat-Treatment on the Mechanical Properties of 1 per Cent Carbon Steel, by H. J. French and W. George Johnson; Tech. Paper 207, Manufacture and Properties of Steel Plates Containing Zirconium and Other Elements, by George K. Burgess and Raymond W. Woodward; Tech. Paper 208, Weighing by Substitution, by C. A. Briggs and E. D. Gordon.

NEW BUREAU OF MINES PUBLICATIONS: Schedule 18, on "Procedure for Establishing a List of Permissible Carbon Monoxide Indicators." Tech. Paper 278, The Sugar-Tube Method of Determining Rock Dust in Air, by A. C. Fieldner, S. H. Katz and E. S. Longfellow; Tech. Paper 281. The Use of Electrolytes in the Purification and Preparation of Clays, by H. G. Schurecht; Tech. Paper 282, Analysis of Detonating and Priming Mixtures, by C. A. Taylor and W. H. Rinkenbach.

THE DIVISION OF THE STATE GEOLOGICAL SURVEY, State of Illinois, has issued Bull. 26 on "Coal Resources of District IV," by Gilbert H. Cady.

IN THE MODERN EXECUTIVE'S LIBRARY the H. E. Wilson Co., New York City, is entering into the field of business and industrial administration with a series of books similar in plan to its Handbook Series on current topics that are known in the educational field. This new series will include books of immediate practical value in every line of importance to business and industrial executives. Daniel Bloomfield, under whose general editorship the Modern Executive's Library will be built up, is a member of Bloomfield & Bloomfield, the Boston firm of lawyers and consultants in industrial relations. The Modern Executive's Library will be divided into Management Series and Industrial Relations Series. In the Management Series the following books are in preparation: Financial Incentives for Employees and Executives, by Daniel Bloomfield; Practical Psychology for Business Executives, by Lionel C. Edie; Personnel Problems, by Daniel Bloomfield. The following titles in the same series have been published to date: Employees' Magazines, by Peter F. O'Shea; Standard Practice in Personnel Work, by Eugene J. Benge, with an introduction by Daniel Bloomfield. In the Industrial Relations Series the following volumes have been published: Employment Management, by Daniel Bloomfield, with introduction by Meyer Bloomfield; Problems of Labor, by Daniel Bloomfield, with introduction by Meyer Bloomfield; Modern Industrial Movements, by Daniel Bloomfield with introduction by Meyer Bloomfield.

SANITATION AND SEWAGE DISPOSAL FOR FARMSTEADS AND COUNTRY ESTATES. By William Paul Gerhard. Price 30 cents. Copies can be obtained at 17 West 42d St., New York City.

THE UNIVERSITY OF ILLINOIS has issued Bull. 127, on "Sound-Proof Partitions," by F. R. Watson, and Bull. 126, on "A Study of the Effect of Moisture Content Upon the Expansion and Contraction of Plain and Reinforced Concrete," by Torata Matsumoto.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold a joint meeting with the Pacific Division of the association, on the occasion of the annual meeting of the latter, in Salt Lake City, June 22 to 24.

AMERICAN ASSOCIATION OF ENGINEERS will hold its eighth annual convention at Salt Lake City, Utah, June 4-6.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Baltimore, April 27, 28 and 29, 1922. Headquarters will be at the Emerson Hotel.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Rochester, N. Y., during the week of June 5, 1922. Meetings will be held in the spring instead of in the fall as heretofore.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its summer meeting at Niagara Falls, Canada, June 19 to 22. Headquarters will be at the Clifton Hotel.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its nineteenth annual meeting at Bigwin Inn, Bigwin Island, in the Lake of Bays district, Ontario, Canada, on June 21, 22 and 23.

AMERICAN OIL CHEMISTS' SOCIETY will hold its annual meeting at the Grunewald Hotel, New Orleans, La., May 8 and 9.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS will hold its spring meeting at Atlanta, Ga., May 8-11.

AMERICAN SOCIETY FOR STEEL TREATING will hold a sectional meeting at the Bureau of Mines auditorium, Pittsburgh, Pa., on May 25 and 26. The International Steel Exposition and Convention of the society will be held in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-fifth annual meeting June 26 to July 1, at Atlantic City, N. J. Headquarters will be at the Chalfonte-Haddon Hall Hotel.

AMERICAN WELDING SOCIETY will hold its annual meeting April 26-29 at the Engineering Societies' Building, New York City.

ANNUAL SAFETY CONGRESS of the NATIONAL SAFETY COUNCIL will be held in Detroit, Mich., Aug. 28-Sept. 2.

CANADIAN INSTITUTE OF CHEMISTRY and the SOCIETY OF CHEMICAL INDUSTRY will hold their annual meetings in Ottawa May 15-17.

CERAMIC SOCIETY (London) is to have a foreign trip to Sweden and Denmark from May 27 to June 10.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY will hold a meeting at Lyons, France, June 27 to 30.

IRON AND STEEL INSTITUTE (British) will hold its annual meeting on May 4 and 5 at the House of the Institution of Civil Engineers, Great George St., S. W., 1, London.

NATIONAL ASSOCIATION OF PURCHASING AGENTS EXPOSITION (the "Informashow") will be held in connection with the seventh annual convention of the association at Exposition Park, Rochester, N. Y., May 15 to 22.

NATIONAL COAL ASSOCIATION will hold its annual meeting at Congress Hall, Chicago, May 24-25.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (EIGHTH) will be held in New York Sept. 11-16.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NATIONAL FERTILIZER ASSOCIATION will hold its twenty-ninth annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 12.

NEW JERSEY CHEMICAL SOCIETY will meet at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its national convention in Detroit, Mich., April 26-28.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists Club, New York: May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting: June 9—American Chemical Society, regular meeting.

The Persistent Relativity of Things

THERE is something that everybody knows in a kind of a sleepy, half-awake, dull way; that he carries along rather beside than within his consciousness; as though he had the information stowed away in some compartment of his brain to which the door is closed. This something is the fact that Society does not stop when any of us dies, and that the world does not stop when we come to the custom house, and that even if we mind our own business we are not always sure to tread the path of wisdom.

It was not many years ago when the last thing on earth that any government would give up was the issuance and coinage of its own money. Today everybody is looking for some kind of international currency with which to trade, and we are beginning to realize that if nations would merely live on the same earth with one another and without even attempting to make a show of comity, they must have tokens and conventions over and above their respective boundaries.

We have no international propaganda to offer, and we are wholly out of sympathy with our lately naturalized fellow citizens of the soapboxes who prefer a Soviet government to that of the United States. But we must learn to think across the borders of our own bailiwicks, our own language, our own interests and our own lives.

With increased means of communication and transportation this earth is growing smaller every day, so that our lives and activities, even at great distances apart, overlap each other in increasing measure. Indeed, if we are not mindful of our potentialities of nuisance and of destruction we may be sure others will discover them for us—and they will call a halt if we haven't sense enough to stop of our own accord.

We have suffered a great deal in this country from the stripping of transportation systems and of industries to make profit for temporary stockholders. We are still pretty sleepy and drowsy while this unconscionable chicanery is going on and we seldom wake up until the damage is done. We must, for the sake of safety, get a bigger vision of things than most of us enjoy, and to those of us to whom this is impossible—to the 12-year-olds in mind who are willing to try anything because they cannot co-ordinate cause with effect—the only safety is to get the light from those who can see. We must have trade with Europe, we must conserve our industries, and we must provide for decent lives for all the people who work for us. We must look beyond our own interests and see what harm our good may do. A year ago we were all talking about relativity. Have we forgotten that there is such a thing? Has the sense of relativity departed from the world just as the nature of it was made manifest?

On Writing Technical English

THE other day a very kindly and appreciative letter came in from one of our subscribers who is eminent in chemistry. It commended some writings about a subject that is difficult of exposition, and was just the sort of a letter that encourages an editor to do his best. It contained also a word of gentle criticism. The writer regretted that at times the language fell below the dignity of the subject, as when the author spoke of the periodic table as "the blamed thing," and again when he says that he "once attended Sunday School."

"De gustibus non est disputandum." And yet, the next time we are born in this vale of tears, if we have our own way about it, we propose to promulgate a Gospel of Good Taste and to establish tests to determine who may be admitted to the shrine as adepts and who shall be cast into outer darkness. That will keep out all those who try to be funny in the wrong place along with those who are without a proper sense of the things we like best. We propose to do this even if, in the end, we ourselves land in the outer darkness. We confess it does give us a pain when reading something serious to find a poor joke languishing alone, like the last rose of summer, to liven the text. But there is the new-Sunday-go-to-meeting-suit-of-clothes style of scientific literature that bothers us also. This is practiced by many distinguished men who do not hesitate to use as ugly a word as specificity without a thought that a sound like that is an offence against good taste.

Science suffers from the ugliness of its language. Any old word to express the meaning has been seized upon, irrespective of its artistic faults. That is because the language of science is young and has not had the time to grow civilized. We can't even agree about spelling or pronunciation. In English some of us are disposed to worry about the vowel "i," and to shorten it as often as we can. By right of custom it often holds its place in iodine, but the other halogens become "bromeen," "chlorinn," etc. Germans grow nervous over the vowel "y" and usually pronounce it falsetto. Some of us say catalyst, but others use catalyzer—which does not seem to be an improvement.

The late WILLIAM JAMES introduced slang into philosophy—and he did so to the advantage of philosophy and psychology. But he was such a master of letters that he decorated diction with slang, just as the profanity of the late Mayor LIVINGSTON MIMS of Atlanta had its own quality of elegance. It is hard to introduce these subtleties into scientific writing, for it is in the lighter steps that we are bound to show our leaden feet. The main thing in writing is to get the idea across, and we constantly urge our contributors and try ourselves to write as though we were talking to the reader, and as if both reader and writer were engaged in a pleasant

effort with all their electrons, to reach a common understanding. Bring in the Sunday School or chewing gum or mothers-in-law or goats or flappers or the Volstead act or anything else, if it will only help. But if such things serve only as unrelated contributions to the humors of science, then our friend is justified in his criticism, and they should be avoided.

Ghosh

All Hemlock

IT DOES BEAT ALL what difficulties we find in the search for the solution of solutions. When we old fellows were young, solutions were about the simplest things in chemistry: you dissolved the solute in the solvent, and there you had it. That was all there was to it. It worked perfectly so long as you didn't worry about it. Of course, as soon as people began to call for investigations as to the behavior of bodies in solution the troubles began, and a promising young fellow named ARRHENIUS, who couldn't sleep because of his questing, conceived the idea of electrolytic dissociation. In the course of time we accepted the idea, but we might as well admit that it was unwillingly done and that if it had not been for OSTWALD and VAN'T HOFF we might still be discussing the subject in the manner of Kentucky theologians and WILLIAM JENNINGS BRYAN.

But really, our thinking (which we had learned) had to do principally with dilute solutions. When ROLLO'S uncle advised him how to study chemistry the old gentleman said:

I used to think theology
Was rather rough on doubt,
But chemistry with ions beats
Theology all out.

You'd better join the church before
Your course is well begun
Because you'll need to exercise
The art of faith, my son.

Solutions you'll discuss at length,
Provided always they
Contain solute to solvent as
The needle in the hay!

There was the trouble. As long as we had a substance in solution in the relation of one small needle to one large haystack, everything went well. Concentrated solutions were a nuisance; they were solutions, all right, but they did not behave according to the rules that we had learned.

Then along came a gentleman with the most picturesque name in chemistry—so far as any one with New England affiliations is concerned. His name is GHOSH, JNANENDRA CHANDRA GHOSH, from far-away Calcutta.

Now "Gosh" is a word that has probably wandered over into colloquial English use through the medium of Sanskrit, and when we say, "Gosh all hemlock!" we indicate surprise, amazement and sometimes despair. In this solution business Dr. J. C. GHOSH became a very present help in time of trouble. While the subject was getting pretty hard for some of us, he came forward from the banks of the Hoogly with everything explained. No matter how strong the solution, said he, any dissolved salt is completely ionized, and the little ions are all arranged in orderly rows in the solution, just the same as the atoms of the same salt are arranged in the crystalline state, as recently expounded by the modest BRAGGS, father and son. That is, we were told that the ions arranged themselves in a kind of a submarine lattice formation. They are like children, we were to understand, sitting on their benches at school; at a co-educational school, in fact, because they tend to form "completely saturated electrical doublets" with their oppositely charged neighbors. But even as the course of true love never does run smooth, so some of the ions have energy enough to break away from their mates, according, by GHOSH, to Maxwell's law of the distribution of velocities. These more venturesome ones thus become the "free ions," which conduct the current, whereas the more tranquil pairs, being bound, hold fast to that which is good, refuse to be parted from one another, and so do not conduct.

Isn't that a pretty theory? And it explains everything. The trouble begins for some of us when we want to prove it, and, digging back into the storehouses of our scholarship, we find ourselves lacking in the needful familiarity with differential equations and thermodynamics and those other enticing studies which seemed too theoretical for such eminently practical men as we were resolved to be when we were young. But Dr. GHOSH, he knows mathematics backward and forward, and he adds a little to the postulates we have outlined above and digs down into the depths of his learning and brings up the expression "virial" and the formula $e^{-\frac{A}{nRT}}$ and emerges with some beautiful equations which demonstrate that everything is just as he said it was. They show perfect agreement with all the experimental results on conducting solutions that ever found their way into print. Then we admire those long and involved equations and formulas, and, like the boards of directors of some chemical works when they get a report of the progress of research, we approve, accept and place them on file. We can't follow "very well," as we admit, but we applaud. Why, not long ago the learned Faraday Society in London held a symposium on ionization, and one gentleman present declared that the theory of GHOSH marked the greatest advance in physical chemistry since the revelation of the Ostwald-Planck dilution law.

But now is our complacency sore troubled and the waves of doubt encompass us about. In the April number of the *Journal of the American Chemical Society* Prof. JAMES KENDALL of Columbia University contributes an article which attacks our faith and harasses our spirit with all manner of uncertainty. The work of GHOSH has been done after him and checked up in detail with disastrous results. The postulates prove to be inconsistent with each other. The equations do not follow from the postulates, in spite of "virial," $e^{-\frac{A}{nRT}}$ and their companions in obscurity. Worse than ever, many of the calculated results do not follow from the equations. And finally, Ghosh all hemlock, an astounding proportion of the observed results of previous investigators have suffered transmutation in the process of transcription. We know the wonderful work which the veteran KOHLRAUSCH did, and when GHOSH says his theory agrees with KOHLRAUSCH'S data, and gives tables to prove it, what room is there for doubt? None, until we are put wise to the fact that 39 out of 75 of KOHLRAUSCH'S values, as given by GHOSH, are not the same as in the original.

And so we are sent out to wander in the wilderness again! Solutions have not yet been solved after all! Ghosh all hemlock!

The Ignorant Forge Shackles for Progress

UNDER the mistaken idea that democracy consists in letting everybody decide everything for himself whether he knows anything about it or not, we have struck the severest blow to representative government that it has ever received. We have made party leadership irresponsible. Senators are now both nominated and elected by popular vote, and the quality of the Senate has gone off. And as representative government weakens under government by harangue, the always-ready oligarchy steps in and takes the reins in the disorder which follows. We have lost the checking system of government that the founders were thoughtful to provide when we let ourselves be carried away by direct nominations and threw the obligation and responsibilities of representation on the people.

The more we encourage government by speech-making the more we give up our rights and privileges as citizens and our liberties. Utterly irresponsible legislators, nominated and elected by grown-up children, and a curious group of leaders who are constantly engaged in doing battle against intelligence propose measures that take from us that which we hold most precious: our liberty of thought and of speech. The statute lately proposed in the State of Kentucky and which failed of adoption by a single vote sounds like a joke; but it is not. It isn't even funny. It proposed under severe penalties to prohibit the teaching of the principle of evolution. WILLIAM JENNINGS BRYAN has a new speech about it and he is making a profitable journey through the country, appealing to the ignorant, to deny the right of freedom in the study and teaching of geology, biology, comparative anatomy, anthropology and the whole gamut of science wherever it interferes with the exact letter of the first chapter of Genesis. The reason for this is that it does not accord with the bias of a limited number of persons in regard to what they think is religious teaching, but which is not religion at all. It does not accord with their particular dogma. That is all.

The opponents of evolution of this generation are principally those who for lack of mental capacity cannot comprehend the nature of progress. They cannot see beyond tradition. And the theory of human evolution does not include them in its workings.

The anti-evolution propaganda is no less than an effort to forbid all teaching that is not approved by a board of ecclesiastical censors drawn from the most ignorant. Objection to these amazing restrictions on freedom of thought is as common among enlightened churchmen of all denominations as it is among men of science.

Where then is the danger? It consists in our good-humored listening till BRYAN and his ilk get a following. Soon such a following will make noise enough for the weaklings nominated to legislative office to hear the sound and think it represents votes. Then, before we know it, by threats of the minority that hold these views, we find the statutes enacted, the Constitution amended—and our liberties gone.

It is time now to tell those who constantly offend against intelligence that we purpose to retain our liberties and to put ourselves to the discomfort of showing that we mean it. It is an unpleasant, noisy job, but the situation demands it. It is time for men of science to speak.

New Lines of Production Needed

ONE of the difficulties in appraising the economic needs of the present time is the distant mental vision of pre-war times. We are apt to feel, now that the war is over, that we ought to begin where we left off. We have economic problems, and those that seem to result from the war receive much attention, while little attention is given to the fact that just before the war we also had economic problems, and the war did not settle those problems.

No one wishes to start an argument as to who or what caused the war, but it is permissible to recall, merely as a convenient aid to memory, that early in the war there were cited many economic facts such as would tend to produce war. Prominent among these was what is called "overproduction," wherefor "new markets" were being sought.

It is very curious that reference to "overproduction" so frequently produces a mental concept in terms of aggregate instead of individual industries. While we have learned something in this respect in recent years, even today the thought in many minds is that the United States possesses too much productive capacity, from which some men seem to deduce that we should encourage all exports and discourage all imports.

In the early stages of any industry progress is usually slow. Then, as technique is developed, production per unit of equipment increases and costs decrease, whereby demand increases through the increasing cheapness. The owners, who are merely human beings, acquire a slightly exaggerated idea of their product's importance to mankind, and give little thought to the possibility of a saturation point. The natural result is that there is what is called "overproduction" of this commodity, which means simply that development along that line has gone too far and others that could be developed are being neglected.

In the latter part of the nineteenth century there was what was called "overproduction" in the United States and elsewhere, and the condition continued in the new century up to the beginning of the war. We should now remember that the condition, however erroneously described or misunderstood, existed before 1914—not all of our present difficulties are the product of the war.

On the contrary, the war accentuated some of the undesirable conditions that already existed, causing, for instance, the further expansion of industries that had already reached or passed the point of full development to meet the desires of the people, and furthermore the period since the beginning of the war has been singularly bare of discoveries and inventions giving men opportunity to work in producing new things that the public may want.

It would be ludicrous, if it were not tragic, how widespread is the notion that our industries are here and simply must be kept. Continually references are being made to this industry or that industry operating at such and such a percentage of its "capacity," plainly with an inference that conditions will be right and conducive to our complete and continued welfare when each industry is "operating at 100 per cent." That is altogether too easy for this world. Instead, we are lined up for more changes than ever, not merely to correct distortions produced by the war, but to correct many that had developed long before the war.

Electric Cast Iron

Symposium by American Electrochemical Society Considers Manufacture of Pig Iron in Electric Furnaces, Manufacture of "Synthetic Cast Iron" From Steel Scrap or Iron Turnings, Melting of Pig Iron by Electricity, and Desulphurizing Cupola-Melted Gray Iron

A DAY-LONG DISCUSSION on all phases of electric cast iron was held in Baltimore, Thursday, April 27, by the American Electrochemical Society. Starting with Heroult's experiments at Sault Ste. Marie, papers and contributed remarks carried the subject into nearly all corners of the field which have been explored or occupied since that time.

Smelting Furnaces

A very good case for the open-top furnace, for the production of pig iron from ore, was made out by R. C. Gosrow in a paper entitled "Shaft vs. Open-Top Electric Furnaces." Disregarding at least one intermediate type, there are two practicable ore-smelting furnaces. Shaft furnaces, either with closed or open top, are useful for drying and calcining the charge before it reaches the reduction zone. Gosrow doubts whether any reduction of ore by ascending hot gases occurs, a doubt voiced by many auditors, but it is difficult to see why this should not occur, if, as said by the author, "the stacks were constantly frozen up with the charge, which fused [sintered?] by contact with the hot exit gases." Sticky charges are associated with slips, broken electrodes and superheated and smashed linings. Variable operating conditions are furthermore caused by segregation of even a carefully prepared charge during a descent down a tall shaft, and the variable electrical conduction by irregular settlement of the charge and after molten metal is tapped from the furnace.

While F. Hodson was sure he had seen gray iron tapped from a Swedish shaft furnace, several other speakers, notably Dorsey A. Lyon, said that the product was not a pig iron, as this was known to the foundry trade, but a hybrid metal, a white iron for steel making containing 2 to 2¼ per cent C. Swedish furnaces seldom met predictions as to cost of operations, but many of their early troubles have been successfully overcome. Roof failures, near the electrodes, have been controlled by gas circulation (really the main value of this operating feature except perhaps in the larger furnaces, where a little pre-reduction may be effected thereby) and the Soderburg self-baking electrode has solved many troubles originating at the carbons. From the standpoint of comfort to the workmen, there could be no comparison—to a casual observer the Swedish furnaces do not appear to be smelting, while an open-top furnace is a good imitation of hell. This term is purely relative, however, as demonstrated by Robert Turnbull, who offered to exhibit a 20,000-kw. open-top furnace which was no more uncomfortable than a crucible melting shop. He also insisted that "hand stoking and the correcting of the position of the electrode in the charge is more than half the battle, and such work is impossible in the shaft furnace."

Turning to the merits of a rectangular open-top furnace with a shallow ore bed and of at least 7,000 kw. capacity, Mr. Gosrow pointed out that the operation could be much more closely controlled because variations in smelting rate quickly show in the conditions at the top of the charge, and the necessary correctives can be got down to the smelting zone—or for that matter, if charging is stopped the charge works down so that wall accretions can be barred off or proper flux charged alongside, or in bad cases the furnace can be drained completely in a few hours. Much stress was laid on the advantage of placing the charge just where it is wanted, with the assurance that it will not be badly segregated by the time it reaches the smelting zone, or the charcoal crushed and the charge compacted by the excessive overburden. "The initial cost of construction is lowest and the cost of maintenance is also the lowest." A detailed estimate of the smelting cost totals $40 per net ton of iron in a proposed Western plant to produce 20,000 tons a year, a cost which apparently is liberal, since Messrs. Fitzgerald and Turnbull noted that the current consumption and the electrode charges were very liberal, not to say extravagant, whereas the plant itself could probably be built for half the estimated $750,000.

Robert Turnbull noted that there was no question that the open-top furnace was economical, despite the fact that none are now in operation making pig iron. Heroult's experimental runs at Sault Ste. Marie have never been bettered, if approached[1]. The operators at Heroult, Cal., were never able to produce gray foundry iron consistently, but no trouble was experienced at the Sault, where all tappings were of gray iron with 3 to 4 per cent C.

Carburization of Iron

Whether or not the necessary balance between carbon and silicon could be attained so that gray foundry iron could be produced in a pit furnace depends to a large extent on the rate of absorption of solid carbon into molten iron, since the zone of reduction and carburization by CO gas is practically non-existent. It has also been very difficult to get more than 3 per cent C into "synthetic pig iron" made by melting iron sponge or steel scrap in an electric furnace. Furthermore, it has been found impossible to melt iron sponge in the open hearth and carburize it without melting down the roof, although it is reported that heats containing 80 per cent of "purple blocks" (briquetted sponge iron) are being melted in Sweden with the introduction of 3 per cent carbon.

Therefore, "A Study of Carburization in the Manufacture of Synthetic Cast Iron," by Clyde E. Williams and C. E. Sims, was given particular attention. Most of their experiments were made in a small tilting furnace, holding 300 lb. of metal. Mild steel punchings and clippings were mixed with about 20 lb. of carburizer (crushed through 10 mesh), melted, necessary

[1]Certain ores were smelted with 2,000 kw.-hr. per ton, whereas the best Swedish furnace uses 2,500 kw.-hr.

ferro-alloys added, and sampled periodically. Temperatures varied not more than 50 deg. during a single run, and seldom mounted higher than 1,450 deg. C.

Table I shows the results of a series of runs on various carburizers. Practically all of the carbon contained at the end of the melting stage was picked up immediately upon melting, for if steel clippings were melted before the carburizer were added, samples would analyze 2.7 per cent carbon after a few pounds of graphite was thrown in. Graphite is a better carburizer than charcoal, because it is much easier to keep it in contact with the iron. Its commercial use would be restricted by the limited amount of electrode butts available. The table also shows the advantage of using low-ash coke.

TABLE I—ABSORPTION OF CARBON IN IRON CONTAINING 2 PER CENT Si

Carburizer	At End of Melting Stage Time (Min.)	Carbon Content	At End of Experiment Time (Min.)	Carbon Content
Acheson granular resistor graphite	190	3.0	260	4.1
Coal tar coke, 4 per cent ash	150	2.5	230	3.8
Coke, 12 per cent ash	160	2.3	270	3.6
Coke, 25 per cent ash	110	2.1	300	3.0
Charcoal	130	2.2	270	3.3

Robert Turnbull made a considerable quantity of electric pig iron during the war, and found that 2½ per cent carbon was about the maximum he could introduce with lump charcoal; crushing the charcoal for better contact boosted the carbon to 3 per cent; finally, by using silicon carbide (carborundum fire sand), he was able to increase the carbon to 3½ per cent, introducing 1 per cent silicon at the same time. The present authors also find that if silicon carbide is added after high-ash coke has been used, the carbon is increased from 3.1 to 3.9 and silicon increased 1.55 in 8 minutes.

Silicon in iron up to 7 per cent and phosphorus up to 0.8 per cent apparently makes no difference in the amount of carbon dissolved, but 1.75 per cent manganese iron carburizes a little more rapidly than one containing 0.40. Sulphur uniformly retards the rate and total amount of carburization.

Slags would be expected to retard carburization by preventing physical contact, iron to carbon. This indeed occurs, except when working under a desulphurizing slag, when the iron is carburized rapidly, possibly because calcium carbide in the slag transfers its carbon to the iron more easily. George K. Elliott said that this was possibly also due to the simultaneous lowering of sulphur. At Aniston, Ala., it is the practice to "pole" the charge, or stir it with a green pole, when making electric furnace wash metal. In this way sulphur is reduced to 0.03 and carbon up to 3.9 to 4.0 is absorbed from low-ash coke with no trouble. Low-sulphur frees manganese from the sulphide and allows it to form a corresponding amount of carbide.

Carburization in the Cupola

If straight steel charges are melted in the cupola with the proper coke, the resulting iron could ordinarily be expected to contain 2¼ to 2½ per cent carbon. Six times as much coke would probably have to be burned in order to boost cupola melted steel to 3½ per cent carbon, although a mixture of scrap steel, plus a small quantity of cast iron, plus a little high-grade ferrosilicon has been used to make low-phosphorus bessemer pig containing 2½ to 3 per cent C. Richard Moldenke mentioned some recent German practice of interest in this connection, where synthetic pig iron for malleable and low-carbon (2¼ to 2½ per cent) castings are made in a cupola. The charge consists of two kinds of briquets: First, steel clippings or borings heated to redness in a rotary furnace by a strongly reducing flame, a certain quantity placed in the lower, box-like die of a forging hammer, and welded into a pancake of high density by two or three vigorous blows; second, pig-iron shot and ferrosilicon cemented into small bricks.

Synthetic Cast Iron

James L. Cawthon, in a paper on "Synthetic Cast Iron," discussed methods of applying these principles to the actual production of cast iron from machine shop scrap (steel turnings). When this is melted in either an acid or basic electric furnace with 75 lb. good coke per ton, it will come down with about 2.5 per cent carbon, and well deoxidized. Melting under a carbide slag in a basic furnace will not change this carbon analysis nor affect the manganese or phosphorus, but silicon will be reduced practically to zero, and sulphur cut in half. Acid furnace melting without slag brings down metal unchanged in S and P; about 50 per cent of the Mn has slagged, while a little silicon has probably been picked up from the furnace. If desulphurizing is unnecessary, the acid process will prove cheaper and simpler, and give less trouble with slag when pouring the iron.

More carbon can be added only by stirring carbon into hot clean metal. Cawthon recommends skimming the bath carefully, adding 50 lb. fresh coke, raising the temperature as far as the furnace will safely stand, and stirring the bath with a green pole. Ten minutes poling will increase the carbon 0.50; another equal portion can be absorbed by repeating the operation. Some silicon can be reduced from an acid slag, but ordinarily it will be cheaper to add 50 per cent ferrosilicon just before tapping. Provided two or three times as much Mn is present as is necessary to form MnS, and C is 3.25 or over, a further fractional percentage of manganese does not affect the physical properties of the cast iron materially. Ferromanganese will be absorbed by the metal quantitatively if added to a basic heat at any time; at least 15 per cent is lost when adding at the very end of an acid heat; none is lost when adding the alloy to hot metal in the ladle.

Since phosphorus is eliminated at a fairly low temperature and under highly oxidizing conditions, it will remain practically constant in a high temperature carburizing operation. If phosphorus under 0.03 per cent (washed metal) is desired, it can be had by melting steel scrap in a basic furnace, with additions of lime and iron oxide. After melting, the phosphorus slag is removed, leaving behind "wild metal," which will violently boil when the first shovel of carbon is thrown in. This boil should be checked by 3 lb. of ferrosilicon fines, whereupon carburizing can proceed in the usual way.

A useful furnace test is described by Mr. Cawthon. He casts a test bar, 1 in. diameter, 6 in. long, in a dry sand core block, it is shaken out after 3 minutes, and quenched after 7 minutes further air cooling. A fracture is studied; one break is ground and tested for Brinell hardness. If the metal is harder than experience indicates is desirable to match the specification, carbon or silicon should be raised by additions, depend-

ing upon the indications of the fracture; if the hardness is too low, more low-carbon steel scrap is added.

Field for Process

In a paper entitled "Synthetic and Electric Pig Iron Sanely Considered" Robert Turnbull expressed the opinion that notwithstanding the fact that little or no synthetic pig iron is now being made anywhere, it is a logical operation for iron foundries having electric furnaces making either gray iron or steel castings, of both; the same furnace serving for both. Indeed this exact condition at Treadwell, Alaska, was described in a paper by W. E. Cahill, entitled "Electric Furnace Iron and Steel. Intermittent and Alternating Operations."

Synthetic iron is also the best solution for the problem of producing pig iron in countries far removed from coke and producing furnaces. Iron from scrap in an electric furnace will in most cases prove far cheaper than electric furnace production of iron from ore. Despite the difficulty in charging, and in getting high carbon into a low-carbon bath, the steel furnace is to be recommended over the open-top smelting furnace, because the closed furnace is more flexible and can be operated with refining slags. Refined iron, as a matter of fact, does not need as high carbon as ordinary cupola metal.

A supply of cheap iron or steel borings is a very attractive raw material for excellent castings at a price which may compare favorably with cupola melting from expensive pig.

Melting Cast-Iron Borings

Just how cheap the electric furnace and how dear the cupola iron will be depends to a certain extent upon who makes the estimates. Disregarding some evidently erroneous figures submitted in one of the papers, E. L. Crosby told of a foundry in Detroit which could buy borings at $8 per ton and used them for 100 per cent of the charge. Their current consumption was 600 kw.-hr. per ton under 8-hour operation, or 500 to 525 kw.-hr. per ton for 16-hour operation. Paying 1.8 cents per kw.-hr., they were able to produce molten iron from borings for $23.60 per ton, whereas cupola iron, made right alongside, cost $25 per ton. This tells only part of the story, for the rejections, both in foundry and in machine shop, were sharply reduced. Consequently it would probably be cheaper to use electric iron even if the borings cost 50 per cent more.

F. W. Brooke pointed out that one feature often overlooked by furnace estimators was that material absorbed heat at different rates, and that the same material varied with its physical condition. Cast-iron borings melted particularly slowly, and were quite liable to melt from the top; whereupon the arc would melt about as much furnace as metal. This trouble is largely obviated by methods described by H. M. Williams and T. B. Terry in their paper entitled "The Melting of Cast Iron in the Booth Rotating Electric Furnace." Using a very small furnace, holding from 250 to 280 lb. metal, it is actually easier to melt turnings than a mixture of pig and scrap, possibly due to the washing action of the molten charge on the finely divided solid.

No refining is attempted; additions are made with a small spoon thrust through an electrode hole. Temperatures are regulated by watching the current input; operations having been standardized so that the furnace may be poured by wattmeter. Melting losses amount to 4 per cent on pig and scrap, and 7 per cent on clean borings. No material change in chemical analysis is noted, except sulphur goes up about 0.01 per cent, either from a habit which sulphur has, errors in sampling, or dirt or cutting oils adhering to the scrap.

Duplex Foundry Iron

George K. Elliott reviewed the foundry practice of duplexing with cupola and basic electric hearth. Small heats of special iron may advantageously be melted in the electric furnace, but since the cupola is able to melt 8 tons of iron with 1 ton of coke, there are few locations where electric energy can compete. A cupola is a wonderful melter, but it introduces 0.03 S into iron on each melting, and in careless hands will deliver highly oxidized and gassy metal. Whenever these limitations of the cupola, or the cost of available raw materials, or the shifting from price per pound to quality per piece, or all of these factors together, become of considerable importance, a basic electric furnace should be introduced to refine the molten iron delivered by the cupola. Cast iron can be deoxidized and sulphur reduced from 0.18 per cent to under 0.07 in about 30 minutes, changing poor castings into uniformly good ones. Some 0.15 S irons, even some 0.25 S irons, produce acceptable test-bars, especially in England, but at the Lunkenheimer plant in Cincinnati it has been found that an important machining operation invariably uncovers "dirty" iron whenever S exceeds 0.09 per cent. Mr. Elliott was of the opinion that impact testing should be used to determine quality on apparently similar irons; a certain obsolete casting was scrapped, and several made of duplex metal and several of cupola metal of substantially the same composition and tensile properties were broken under the drop hammer. Cupola iron broke in two drops; electric iron required four or five drops.

Foundries serving machine shops where intensive production programs are installed should be particularly interested in electric duplexing, since it will enable them to produce unfailingly material of uniform machinability and strength. In figuring the value of the process, one should not reglect the important saving effected through a very much smaller proportion of rejected pieces, especially partially machined pieces. Very hot electric iron means sounder iron, because fluid iron in gates and sinkheads can more effectively "feed" the casting, and the ferrostatic head more effectually prevents liberation of the small amount of residual gas in refined metal. One important point is this—that hotter iron requires more refractory molding sand. While there is little information on the effect of O,N,CO,CO_2 and other gases in cast iron, the influence of oxygen and oxides on the whole is bad, since a certain well-defined kind of bad iron from cupolas is doubtless the result of highly oxidized conditions. Some of these gases may have an indirect effect in causing coarse crystallization and copious deposition of graphite in large flakes; micrographically electric iron is finer grained, the graphite comes down in smaller and more advantageously dispersed particles. Hence the iron may carry more silicon without the usual softening and loss of strength. It has already been noted that desulphurized steel is relatively easy to carburize into synthetic pig; possibly this is more truly due to the previous degasification which is essential before desulphurization is possible, and of which desulphurization is the only indication now furnished by chemical analysis.

Handling the Finished Products of Industry—I

The Necessity for Keeping the Cost of Handling Finished Products at a Minimum—Other Factors Causing the Adoption of Mechanical Equipment for Handling Finished Products—Classification of Handling for Finished Products—Types of Equipment Available and How Used

By G. L. MONTGOMERY

THAT the cost of most products is almost directly proportional to the cost of handling the materials of their manufacture into the works, through the process, and out of the works again, as recently stated by Herbert Blyth,[1] is a fact too evident to require much proof. Over any reasonable period of time, the reductions in cost possible of attainment through reduction in the cost of raw materials, of productive labor, of office and sales overhead, or of fixed charges will be relatively small as compared to reductions in cost possible through the elimination of non-productive labor. In almost any process industry, the greater part of the non-productive labor is entailed in handling the materials. The obvious and true conclusion to be reached in seeking to reduce costs is that the handling routine must be made as nearly automatic as possible so that the costs for this work are at a minimum. This solution is well worthy of adoption and should be put into effect wherever possible. Putting it into effect means the use of material-handling machinery and of other automatic machinery in the process and elsewhere.

Where Automatic Equipment Will Give the Quickest Results

Accepting the statements in the preceding paragraph as a basis for a study looking to the reduction of the costs of producing a commodity and getting it into the hands of the primary consumer, let us survey the present use of automatic equipment for handling and other purposes in the process industries, and determine where in these industries such equipment can be made to give the quickest and most satisfactory results for the least expenditure of capital.

As stated above, this automatic equipment is concerned with getting the materials into, through and out of the plant. In this series of papers equipment is considered as handling equipment whenever it is employed to further the physical movement of the material from the start of the process toward the close. Hence such machines as are commonly called automatics—i.e., cutting, wrapping, bagging, filling and packing machines, etc.—are here included as handling machines, together with the conventionally so-called conveyors, trucks, cranes and so on. Consideration of the three steps—in, through and out—will show where an industry can best start to realize the savings possible if there is no handling equipment employed or where perhaps, if some handling equipment is used, an extension can best be made to give quick results in reducing costs.

The application of automatic machinery to the movement of the raw materials of industry has had a more extended development and has been more widely accepted by the process industries than any other type of handling. Types of conveyors for this purpose such as scraper, drag, apron, belt and bucket, bucket-elevators, and cranes and hoists have reached a state of workability almost approaching perfection, having had their development many years ago in mine and power house. From the ancient mine car drawn by a pony the electric industrial railway and the storage battery or gasoline-motored industrial truck have grown. Locomotive cranes, bridge cranes and similar devices were early used in mines, coal-storage yards and such places. From these uses this equipment has spread to industry in general. At the present time its acceptance and use is on the road to universality.

Of course there are a number of cases where the raw materials are not handled by automatic equipment. Generally it will be found that these cases are where the total amount to be handled is small, or where, while the aggregate may be large, it is made up of a number of diverse materials which for some reason must not be mixed or contaminated one by another. In these cases study has generally proved that the saving incident on the use of handling machinery would not offset the relatively high fixed charges on the installation necessary.

The Status of Inter- and Intra-Process Handling

Mechanically handling materials while they are in process of manufacture is of great importance. No one other thing can have as great an effect in reducing costs of production, increasing production efficiency and lessening the problems of management. Without question, in cases where a new plant is to be erected, new machinery is to be purchased or existing machinery is to be re-arranged, the most complete system of inter- and intra-process handling and the fullest use of automatic process machinery that sound engineering judgment and practical designing and operating experience can recommend will be found a highly paying investment.

But the efficient use of such equipment almost invariably requires an arrangement of process machinery differing from that used with man-power handling and often requires the development of new machines or appliances. These considerations put a necessary brake on any sudden and universal realization of increased production efficiency through extensions of this type of handling. Such a growth will come—but come slowly—as new processes are developed, new plants are erected and existing equipment, through obsolescence, requires replacement.

The Finished Products Present the Best Field for Immediate Savings

Taking the product out of the plant includes all operations which must be performed with a product after the last true manufacturing process is completed, until it

[1] *Chemical Age* (London), Feb. 25, 1922, abstracted in Chem. & Met. Eng., April 5, 1922.

passes out of the ownership of the maker. These operations are really incidental to the distribution and sale of the product, including such items as wrapping, storing, packing, labeling and shipping. Often the cost of this work more than equals all the other charges which the product must bear. It is obvious that any savings that can be made here have a direct result in reducing the price at which the products can be sold and hence enable the sales force to do more effective work. If these savings are made in many industries, the consequent price reductions possible, covering a broad field, cannot fail to stimulate trade—domestic and foreign.

The cost of handling finished products is generally regarded as a necessary evil. Part of this cost is necessary. But the effort to reduce it to its irreducible minimum has just started. Everywhere one sees work of this nature being done by hand, utilizing the labor of hordes of workers, workers who could be and should be trained to real productive labor if it were possible to spare them from their present non-productive tasks.

And it is possible so to spare most of them; but not until the automatic equipment has been installed to take their places. Packing and shipping rooms, distributing warehouses, storehouses, piers, railroad freight terminals and all kindred places in which this non-productive work is performed can get along with fewer workers and do their work in a more efficient, quicker and cheaper way by the use of machines and equipment which has already been thoroughly tried. As an illustration of the difference which the use of such equipment makes, the writer was recently on the freight pier of the Hudson Navigation Co. in Albany, N. Y. The tractors usually employed in loading and unloading the boat from New York City were undergoing their annual overhauling and as a result it had been found necessary to hire more than fifty additional men to handle the work usually done by the tractors and their trailers. This meant that the force on the pier had been more than doubled, conditions being back to the same state as before the tractors had been purchased. The agent of the company stated that the equipment had more than paid for itself in a year and had been a great help to the company in getting its work handled expeditiously.

This equipment is all susceptible of improvement and is constantly being improved. But as it exists today, the results obtained by those who use it warrant full investigation on the part of those who are still using hand methods and justify the statement that the use of automatic equipment for handling finished products is a necessity for those who wish to keep costs low for competitive reasons and still to make a fair profit.

Other Reasons for Using Automatic Methods

Aside from the direct economies to be realized in the use of automatic handling methods for the finished products, there are several additional reasons which make the use of these methods at least advisable. Among these we might mention the elimination of delays obtained by having a continuous flow of product to the desired point at the desired time. Confusion is also eliminated in packing, warehouse and shipping rooms because of the smaller number of workers and the direct pathway which the products take. And also there is a speeding up of the workers without increase in fatigue, made possible by the greater ease of accomplishing the work and the natural human inclination to keep the pace of the machine.

These three factors all have a direct and an indirect effect in lowering costs and increasing efficiency of production, which may be decisive factors in causing the adoption of mechanical equipment. In addition, one result of eliminating delays and confusion, of speeding up the workers and reducing the working force is to do away with much of the burden of management. The first result of this is to make it less difficult to keep the work going smoothly. Following this, ways will be found for economies in the office overhead, and the ultimate result is a further reduction in the price at which the product can be marketed.

Hygiene and Cleanliness as Factors Causing the Use of Automatic Equipment

Often the product of a process industry is one where the conditions of manufacture must be kept at the highest attainable point of sanitation, as for instance with a drug or a food product. This naturally means that the surroundings must be as clean as possible, and all contact between the product and the workers reduced to zero or thereabout. There is only one way in which this can be done—by the fullest use of automatic machinery and mechanical handling equipment that can be reached. This consideration of cleanliness applies more to the finished products than to other phases of the industry, for there is no further possibility of sterilization or purification after the process is completed. Any contamination which may occur in wrapping, packing or shipping or other operation which the finished product undergoes has a direct effect in lowering the sale value of the product and hence increasing the relative cost of production.

Psychological Effects of Automatic Machinery

Two other effects of installing mechanical handling for finished products, which are largely psychological, are worthy of note. These are, first, the improvement in the morale of the employees resulting from easier working conditions, lack of confusion, and cleaner, pleasanter surroundings. And, second, the fact that a completely mechanized plant can be made a showplace, and for the public to see a food product or similar article packed and handled in a spotless plant without contact of human hands has a distinct reflection on sales.

Classification of Handling for Finished Products

Handling performed on finished products can be divided into three general classes. First, where the product is in a bulk or unpacked state. In this condition it is least convenient for manual handling; and for cleanliness and many other reasons, it is most necessary to have the handling done by machine. Second, after the product has been wrapped, boxed or crated, or otherwise prepared for shipment and has reached the point where it must be moved through various storing and shipping operations. And third, an intermediate class of handling, coming between the first and second classes, where the bulk or unwrapped product is put into the final container or form in which it is to reach the consumer.

Of the above, the second class presents the place in which handling equipment can most easily be installed and in which the cost of the installation will be least. It is often possible, by the application of a small gravity or belt loader or a storage conveyor or an industrial

truck, without any great change in existing conditions, to effect a revolution in this second class of handling. In most industries, and in the small plants of these industries in particular, this is the place in which the installation of modern handling methods should be started.

In the first class mentioned, handling equipment may be effective in reducing labor and always produces good results by feeding the wrapping or packing operations in a properly continuous manner and eliminating confusion and easing the task of keeping the plant clean. By doing away with the necessity of keeping a large working margin of bulk or unpacked material at the packing room, this type of handling is valuable as a space saver. The equipment used here is often much more costly and heavier than that used in the second class, but its use pays dividends and is absolutely necessary to make a well-rounded system that will give satisfactory results.

In the third or intermediate class, the machinery consists of what is usually known as automatic machinery. This is as truly handling equipment as any other class of handling machinery, for by it the product is moved through a series of operations, and the moving element of the machine is always some true conveyor element as a chain, roll or belt. Such machines are usually a combination of several operations and the movements between them—all in one machine.

This machinery is not applicable to every industry, not being needed in some—as in the brick industry, where a common red building brick after it is burned undergoes no operation to which an automatic machine could be applied. But the use of these machines has not yet been extended to many of the industries where they could effect marked savings, while in those industries where this machinery is already developed its use has not yet fully spread through the industry.

Standard Types of Equipment and Where Used

Class 1. Handling equipment for finished products in bulk or unpacked form:

(*a*) Flat belt conveyors.
(*b*) Troughed belt conveyors.
(*c*) Bucket elevators—various types.
(*d*) Screw conveyors.
(*e*) Apron and pan conveyers.
(*f*) Slat conveyors.
(*g*) Scraper and flight conveyors.
(*h*) Drag chain conveyors.
(*i*) V-bucket and pivoted bucket elevator conveyors.
(*j*) Cranes, hoists and monorails.
(*k*) Storage-battery or gasoline-motor driven industrial trucks and tractors.
(*l*) Lift trucks—hand or power propelled.
(*m*) Compressed air conveyors.
(*n*) Pumps—all types.
(*o*) Industrial railways.

Class 2. Handling equipment for finished products in various kinds of containers, or on platforms or palettes:

(*a*) Gravity roller conveyors.
(*b*) Spiral chutes.
(*c*) Straight slides.
(*d*) Apron conveyors.
(*e*) Slat conveyors.
(*f*) Bar conveyors.
(*g*) Chain conveyors.
(*h*) Flat belt conveyors.
(*i*) Inclined package or barrel elevators—bar, slat or apron type.
(*j*) Vertical package elevators and lowerators.
(*k*) Storage-battery or gasoline-motor driven industrial trucks and tractors.
(*l*) Lift trucks—hand and power propelled.
(*m*) Tiering machines—self-propelled and hand-propelled.
(*n*) Cranes, hoists and monorails.
(*o*) Industrial railways.

Class 3. The automatic machines which handle the product in such operations as cutting, filling, wrapping and packing vary with every case and are impossible to name. They are generally the result of design growing out of special studies and experiments with the particular product and process to which they are to be adapted.

These automatic machines, however, well repay the money, time and effort which their development demands. Often the labor force necessary to wrap a certain number of packages is cut two-thirds by the introduction of such equipment, while the cost of the operation is cut in half. Also, where freedom from contact with the workers is a desideratum for hygienic and sanitary reasons, these machines are a necessity. Other industries have a product that is of a form extremely difficult to pack by hand, as for instance a fine dust or a sticky, gluey mass. In these cases the automatic machine is also of great use. And where the product is dangerous or injurious to the workers, the automatic machine is a necessity for safety's sake.

Illustrations of the Use of This Equipment

In succeeding articles of this series various commercially successful installations of different types of handling equipment used in handling the finished products of industry—such as are mentioned above—will be described. The facts governing the selection of the particular type of equipment used will be pointed out. In all cases where such information is available, the savings effected in costs and the improvements made in the efficiency of the operations due to the use of the equipment will be brought out. By this means it is hoped to point the way to those wishing to realize the economies which have been obtained by others through the use of proper handling equipment, and to establish some criteria by which a handling installation can be judged.

Copper Salts Improve Casein Glue

It has been found that copper salts added to casein glues greatly increase their resistance to moisture and also make them more durable when exposed to the action of molds and fungi.

In the preparation of copper-casein glue at the Forest Products Laboratory, Madison, Wis., 2 to 3 parts by weight of copper chloride or copper sulphate are dissolved in about 30 parts of water and are added to every 500 parts of the ordinary casein, lime and water-glass glue. Copper added to the casein before the lime and water-glass is ineffective.

Glues containing little lime are especially improved by the addition of copper. A low-lime glue with copper may be as resistant to moisture as a glue with more lime in it, and copper does not shorten the "life" or period of workability of the glue so much as more lime would.

Some Facts About Residual Alum in Filtered Water

Graphic Representation of Chemistry of Alum Coagulation Process Emphasizes Interdependence of Various Equilibria and Importance of Hydrogen-Ion Concentration—Use in Explaining Discrepancies in Data on Alkalinity Changes and Residual Alum

By A. M. BUSWELL and G. P. EDWARDS
State Water Survey Division, Urbana, Ill.

VARIOUS material (references 1-13 inclusive) is available in the literature which indicates certain wide limits within which aluminum will be more or less completely precipitated and beyond which it will be partly or completely dissolved. The work of Hildebrand[1] long ago indicated the importance of using the hydrogen electrode for the investigation of certain types of chemical reactions. Later Blum[2] applied this method to the study of determination of aluminum in quantitative analysis. He showed that if the p_H were adjusted to from 6.5 to 7.5 and the reaction mixture then boiled, he obtained complete precipitation—i.e., less than 0.1 mg. in 100 c.c. of the original solution. Since NH_4OH was used as the alkali, heating must have affected the final p_H. Altogether it is evident that Blum's conclusions do not necessarily apply to the precipitation of $Al(OH)_3$ in small quantities in the cold.

In September, 1920, this laboratory undertook an investigation of the various reactions involved in water purification, using the hydrogen electrode as the principal means of carrying out the investigation. The results[3] of this investigation showed among other things that p_H determinations alone were not sufficient for determining the optimum conditions for precipitation of aluminum hydroxide. A different laboratory method of attacking this problem was therefore decided upon.

Since the laboratory procedure chosen was one which involved considerable labor, it seemed advisable to make a field survey of various filter plants in the state in order to estimate the possible practical value of more exact information concerning the conditions for the precipitation of $Al(OH)_3$. It is this field survey which constitutes the subject of the present paper.

Since the completion of the first stage of the investigation two articles have appeared by Wolman and Hannan[14, 15] which furnish a very complete review of the current scientific literature having a bearing on the alum-precipitation question. These authors in their experimental part confirmed the statements of Blum, Mahin and others to the effect that aluminum hydroxide is appreciably soluble at a p_H of 8 or more, probably existing as the acid ion. They further showed that by acidifying their reaction mixture as Blum did to a p_H of about 7 a more complete precipitation was effected. Pirnie[16] has discussed the colloid chemistry of water purification and the relation between alkalinity and coagulation, and Eddy[17] has presented the possible applications of the p_H determinations to filter plant control.

Experimental

The data described in this paper were collected by visiting over twenty filter plants in different parts of Illinois. Due to irregularities in operation at the time of the visit some of the results had to be discarded. The data on twenty-one plants are given. The determination of alkalinity, free CO_2 and p_H were made in the field, while at the same time samples were collected and shipped to the laboratory for the determination of aluminum and iron.

Methods

The determinations of alkalinity and free carbon dioxide were made according to standard methods. Hydrogen-ion concentrations were determined with the use of Clark's indicators and buffer solutions. The analysis of aluminum, iron and phosphorus was made on the residue from a 2-liter sample, which was taken up in hydrochloric acid, separated from silica by filtration and precipitated with NH_4OH according to Blum's method.[2] The ignited precipitate was Al_2O_3, Fe_2O_3 and P_2O_5. Iron was determined colorimetrically according to U.S.P.H. Standard Methods of Water Analysis[18] and phosphorus was estimated colorimetrically by a method given by Deniges,[19] which is briefly as follows: If an acid solution of $SnCl_2$ and an acid solution of $(NH_4)_2MoO_4$ are added to water containing small amounts of phosphorus, a blue color is produced, the intensity of which varies with the amount of phosphate present. These colors may be compared with standard phosphate solutions.

Aluminum was calculated from the difference between the iron and phosphorus and the aluminum, iron and phosphorus.

Reference to such authorities as Aberhalden,[20] Richter[21] and Prideaux[22] indicates that hæmatoxylin is an indicator changing color with the p_H. Hence its use in the aluminum determination would be possible only in a buffered solution. This is accomplished in a measure by blowing breath (CO_2) into the solution or acidifying with acetic acid as recommended by Richards.[23] In addition hæmatoxylin gives various colors with most of the heavy metals. Morison[24] states that "using pure hæmatoxylin a red color was given by the raw water and by a water completely clarified by a dose of alum just sufficient," and Wolman and Hannan[14] state that treated water "showed the usual alumina blue changing to brown with acetic acid." Richards states, however, that the test may be made only in an acid solution in order to avoid the color produced by the alkaline earths. In view of these considerations, the "logwood" or hæmatoxylin test was not used.

Treatment Changes in Alkalinity and p_H

The chemical reactions taking place during coagulation have from time to time been represented in text books and technical articles by various styles of chemical equations. All of these show in the main that 8 mg. per liter of alkalinity will react with 1 grain per gal. of filter alum, forming $Al(OH)_3$. Now, as is very well

known, none of these reactions go to completion, but we have instead a number of reversible reactions each of which depends for its final equilibrium upon all the others. Such complex systems seem to be best represented graphically by the method used by Smith[25] as shown in Fig. 1.

The heavy arrows indicate the direction of the predominating reaction. The substances toward which the light arrows point will be present in relatively small amounts. It should be recalled in this connection that

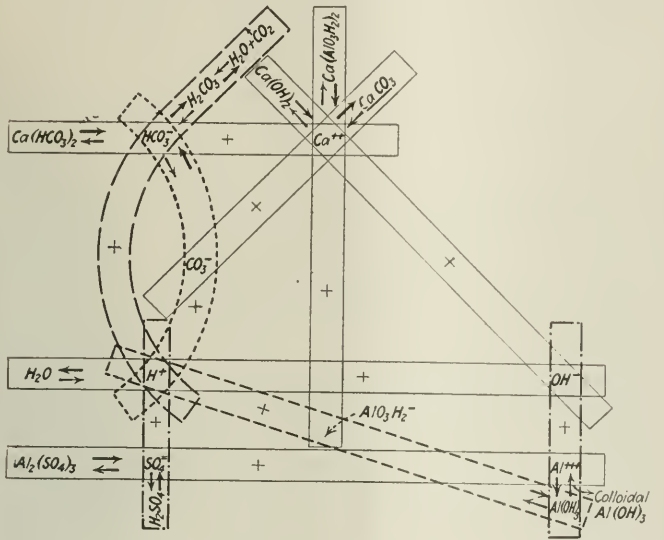

FIG. 1—GRAPHIC REPRESENTATION OF REACTIONS TAKING PLACE DURING COAGULATION

any secondary reaction which tends to remove a product of a primary reaction will increase the amount of the primary reaction in the direction of the formation of the removed product. Numerical coefficients such as are used in "balancing" ordinary chemical equations have been omitted to avoid complicating the diagram. This formulation shows the interdependence of these reactions. It also emphasizes that in each of these equilibria the hydrogen ion plays a part either directly or through its reciprocal relation to the hydroxyl ion. The relation between alum and alkalinity is shown here as in other representations, but it also appears that the loss of CO_2 with the precipitation of $CaCO_3$ may cause a decrease in the alkalinity, and that the addition of lime may cause a net decrease in the alkalinity due to this same precipitation of $CaCO_3$. On the other hand, the formation of colloidal alumina instead of the precipitate would tend to offset the decrease in alkalinity.

TABLE I—ALKALINITY AND $_1$H CHANGES IN FILTRATION

	Alkalinity		Decrease		$_1$H	
Town	Raw	Filtered	Found	Calculated	Raw	Filtered
1	56	62	−6	−12	7.8	8.1
2	116	110	6	5.6	8.3	7.7
3	178	170	8	11 2	8.3	7.5
4	192	186	6	8.0	8.0	7.5
5	180	176	4	8.8	7.6	7.5
6	79	84	−5	2.96	7.5	7.5
7	134	116	18	14.80	8.0	7.4
8	...	124	..	.....	...	...
9	126	112	14	−1.4	7.9	7.3
10	130	108	22	22.4	7.9	7.3
11	160	154	6	21.6	7.3	7.2
12	68	58	10	7.2	7.5	7.1
13	82	71	11	12.0	8.1	7.0
14	58	54	4	3.68	7.5	6.9
15	132	94	38	24	7.9	6 8
16	48	42	6	16	7.2	6.8
17	54	24	30	16	8.4	6.2
18	46	24	22	12.0	8.5	6 2
19	60	16	44	0.8	7.2	6.1
20	24	2	22	16.8	6.8	6.0
21	...	6	..	.....	...	...

An inspection of Table I shows examples of all three of the above-mentioned cases. At four out of nineteen of the plants studied (2, 10, 13, 14) the decrease in alkalinity corresponded to 8 mg. per liter per grain per gal. alum used. At nine plants (1, 7, 9, 12, 15, 17, 18, 19, 20) the decrease in alkalinity was greater than the calculated. This group includes, as would be expected, the three plants at which lime as well as alum was added. At six plants the decrease was less than the calculated.

In addition to those already mentioned we submit the following list of factors which would tend in a measure at least to produce the deviations cited above. Decrease in alkalinity would be caused by: Removal of colloidal iron and aluminum hydroxide and carbonates; removal of alkaline turbidity; titration error caused by adsorption of acid on colloids during titration (Pirnie[16]); excessively acid alum. Factors tending to offset the decrease in alkalinity are: Use of basic alum; precipitation of basic aluminum sulphate instead of aluminum hydroxide; resolution of $CaCO_3$ previously deposited on the sand.

Residual Alum

Reference is made by Wolman and Hannan,[14] Pirnie,[16] Eddy[17] and others to "residual alum" in filtered waters without any statement as to the comparative amounts in the raw and filtered water nor any indication as to what may be a safe limit for this residual alum. The incrustation of sand and distribution mains and the possible adsorption on bacteria (Pirnie[16]) thereby protecting them from subsequent chlorination seem to be the chief objections to "residual alum." Unprecipitated alum has presumably done no work and the inference is that residual alum is an indicator of faulty operation and poor clarification.

Table II furnishes a notion of the extent to which alumina is present in the effluent of twenty-one filter plants in Illinois. In addition to the description of methods given above it should be stated that in all cases except No. 2 the raw water was filtered through Whatman No. 50 filter paper before making the aluminum determinations. Since a comparison of the aluminum in solution or in a fine colloidal state in the raw and treated waters was to be made, it seemed best to exclude the filterable turbidity. The data on No. 2 indicate what the results might have been without the adoption of this procedure. Nos. 12 and 17 are excluded from consideration, since they showed a turbidity in the filtered water of 30 and 25 respectively. Column 2 shows that in only the two abnormal cases, Nos. 12 and 17, does the alumina in the filter plant effluent exceed 2.15

mg. per liter (approximately $\frac{1}{8}$ of a grain per gallon), and further that in thirteen out of nineteen cases the aluminum is distinctly less in the effluent than in the raw water after filtering through filter paper. It should also be noted that although a fairly wide range in p_H value is exhibited by these waters, in no case does the alumina in the effluent reach zero. From our knowledge of the individual plants and their operators we do not feel that this last result can be laid to faulty operation.

From the above data it appears that with reasonably good operation the amounts of "residual alum" occurring in filter plant effluent in Illinois are not such as to be the cause for alarm. Whether or not the condition of the "residual alum" is such that it is more subject to subsequent deposition or adsorption is a question for further study.

Relation of p_H to "Residual Alum"

In the diagrammatic representation of the chemical reactions given above it will be observed that the substances H^+, $AlO_3H_2^-$, $Al(OH)_3$, Al^{+++} and OH^- form a cycle. The reactions may be made to take place in either direction around this cycle depending upon the concentrations employed. Suppose, starting with the substances in the cycle in equilibrium, we take away hydrogen ions; more water will be ionized by the reaction from H_2O in the direction of the light arrow. But this will increase the amount of OH^- present, thereby causing the reaction to go in the direction of $Al(OH)_3$ and removing some of the Al^{+++} from the solution. If the hydrogen-ion concentration is depressed low enough, reaction will take place counter-clockwise in the direction of the light arrow from $Al(OH)_3$ to an appreciable extent, forming some aluminate ion with the side reaction forming some $Ca(AlO_3H_2)_2$. (The aluminate is written in the hydrated form.) If now the hydrogen-ion concentration is increased, the reaction will be turned in a clockwise direction, aluminum will be reprecipitated and later dissolved as Al^{+++}. The exact hydrogen-ion concentration at which the maximum amount of $Al(OH)_3$ is precipitated has not yet been determined. We believe, however, that we are approaching it by slow degrees.

Table III presents a summary of the data collected, the filter plants being arranged in the decreasing order of the effluent p_H values. From column 3 it is seen that with exceptions of Nos. 12 and 17 they also fall in the decreasing order of the residual alum values. To illustrate this point more clearly, the residual alum and p_H values are shown plotted as co-ordinates of points in Fig. 2. Though the points do not lie on a smooth curve, they show a distinct trend toward a minimum of Al_2O_3 at a p_H of about 6. This is much more acid than any value heretofore reported. It is, however, the first value to be determined under operating conditions and with a gravimetric estimation of the Al_2O_3.

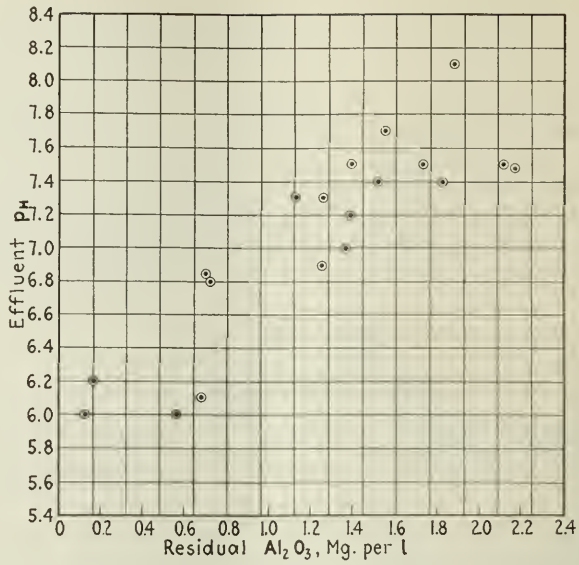

FIG. 2—RELATION OF HYDROGEN-ION CONCENTRATION TO RESIDUAL ALUM

Summary

The chemistry of the alum-coagulation process is represented by a diagram which emphasizes both the interdependence of the various equilibria involved and the importance of the hydrogen ion.

Data on the alkalinity changes during treatment do not check with expected changes as ordinarily calculated. Various reasons for these discrepancies are discussed.

Data presented indicate in general less dissolved alumina in the effluent than in the influent. The amount of alumina in the effluents did not in general exceed 2 mg. per liter.

Points plotted with "residual alum" and p_H values

as co-ordinates indicate a minimum alumina at a p_H of 6, which was the lowest value reached in this series.

Motor Fuel Should Be Basis of Evaluation of Shale Oil

Attempts to evaluate shale oils, even for comparative purposes in the laboratory, involve both technical and economic considerations. From a technical standpoint one must consider and determine what possible products can be reasonably expected from shale oils. From the economic side there must be considered which of these possible products will be in greatest demand and how cheaply they can be placed on the market. Possibly in some sections of the country certain products will be in greater demand than in others; and a discussion of how cheaply these products can be produced and marketed leads to a consideration of plant location, transportation, labor supply and similar economic factors, which each plant must individually solve.

Inasmuch as the chief problem in the oil-shale work of the U. S. Bureau of Mines is to determine the conditions most favorable for the production from different shales of highest yields of best products, it must first consider what these products are likely to be; second, determine the amount of these products in the oils under consideration; and finally, determine the relative qualities of these products from different shales.

During the past several years the petroleum products in the greatest demand have been motor fuels, illuminating oils, lubricants and fuel oils. The demand for illuminating oils is increasing very slowly, and no immediate appreciable increase can reasonably be expected. Lubricants will probably be supplied from petroleum for a great many years, since much of the petroleum and petroleum residuums now burned as fuel can be worked into lubricants when the demand for lubricants increases. Oil will continue to be used as fuel until its price exceeds that of an equivalent amount of coal. The demand for motor fuel is, however, likely to grow at an increasing rate. This being the case, it seems likely that, first of all, shale oil will be used as a source of motor fuel, and secondly, possibly as a source of fuel oil. Other products will probably be of secondary importance, and it has been finally decided that shale oils may reasonably be evaluated on the basis of the amount and quality of motor fuel they will produce.

Determining Penetration of Wood Preservatives

The effectiveness of any wood-preservation treatment is measured very largely by the depth to which the preservative penetrates. This can be determined by the following tests, which are used by the Forest Products Laboratory, Madison, Wis.

The presence of creosote oil is indicated by the dark discoloration, and the degree of penetration may readily be determined by taking a sample at a point free from checks and other imperfections and at a considerable distance from the end. This may be done either with an ordinary ½-in. bit or with an increment borer, which brings out a core of wood that shows in cross-section the depth of penetration and is easily examined. The observation should be made at once, because the oil spreads rapidly over the cut surface. In order to prevent infection, the hole in the treated piece should be tightly closed with a creosoted plug.

As zinc chloride is colorless, the depth of penetration of this preservative must be ascertained by chemical means. After cutting the stick in two or getting a sample with the increment borer, the freshly cut surface is dipped for not to exceed 10 seconds in a 1 per cent solution of potassium ferrocyanide, and the excess solution is removed by blotting paper. The sample is then dipped into a 1 per cent solution of uranium acetate and dried. The treated portions will be whiter than the natural wood, and those untreated will have a dark red or a maroon color. This method does not give very sharp contrasts on wood which is reddish in color, like red oak, but otherwise is very satisfactory.

Another method consists in spraying over the freshly cut surface a mixture of equal parts of 1 per cent potassium ferricyanide solution, a 1 per cent potassium iodide solution and a 5 per cent solution of soluble starch. This colors the treated portion a very dark blue, but does not affect the untreated wood.

Sodium fluoride is colorless and no satisfactory method of showing its presence in wood has been devised.

Mercuric chloride is shown by the blackening of the treated area when dipped in a solution of hydrogen sulphide.

Production of Domestic Graphite

There was a decrease of 88 per cent in the sales of domestic crystalline graphite in 1921 and a decrease of 61 per cent in the sales of amorphous graphite as compared with 1920. The following table shows the sales for the last 5 years:

DOMESTIC NATURAL GRAPHITE SOLD, 1917-1921

Year	Amorphous — Quantity (Short Tons)	Amorphous — Value	Crystalline — Quantity (Short Tons)	Crystalline — Value	Total — Quantity (Short Tons)	Total — Value
1917.....	8,301	$73,481	5,292	$1,094,398	13,593	$1,167,879

The Packed Cell Process for Sulphuric Acid

Description of the Construction and Operation of the 25-Ton Unit at Anaconda, Mont.— Comparison of Efficiencies, Operating and Construction Costs Between This Plant and Modern Chamber Installations

By E. L. LARISON

THE packed cell sulphuric acid process developed at Anaconda, Mont., has shown some unusual results which should be of interest to the industry. This process has been developing in increasing sizes since 1917, up to the present plant with a capacity of 25 tons per day. This last installation involves all the apparatus and construction features which will be required in a plant of any size and has given data for the precise designing of all future installations.

This process is one which, like the chamber process, makes use of the reactions between sulphur dioxide, oxygen, water and the oxides of nitrogen. It produces acid of the usual grades made by a chamber plant—namely, 50 to 60 deg. Bé.

The chief points of interest in the process from the standpoint of practical operation are:

1. Cost of plant for a given tonnage is about 50 to 60 per cent of that of an equally well-built chamber plant.
2. Cost of operation is no more and under some conditions is less than that of a chamber plant.
3. Ground area used is only 30 to 40 per cent of that required for a chamber plant of equal capacity.
4. Process is established much more rapidly than is the chamber process, a valuable quality when plants have to stop and start frequently.
5. The maintenance cost is probably lower than that of a chamber plant, although this point cannot be definitely stated, since the existing plant is only 2 years old.

The packed cell plant consists essentially of a source of SO_2, a Glover tower, packed cells, Gay-Lussac towers, acid coolers, pumps and fans. The chemistry of this process is the same as that of the chamber process. It is to the physical and mechanical conditions created in the packed cells that the remarkable acceleration of the acid-producing reactions is due.

Physical Conditions in the Ordinary Chamber Plant

It is interesting to contemplate what may be called the niter processes in use today. We may consider as one extreme those chamber plants consisting of a small number of enormous chambers and as the other, the process under discussion. It is not intended to convey the impression that from an economic standpoint the large chamber plants are poorest, for that is not the case. They do, however, represent the antithesis in reaction speed of the packed cell process.

In those plants consisting of a few very large chambers, the mixture of SO_2, O, N, water and oxides of nitrogen, coming from the Glover tower, moves in a very slow, tranquil way through the chambers. Mixing or agitation and impingement of liquid particles on solid surfaces are slow and infrequent. Some such plants use over 20 cu.ft. of chamber space per pound of sulphur converted to acid per 24 hours. In these plants, too, the ratio of radiation surface of chamber walls and top to volume is low, and the heat of reaction is dissipated slowly, thereby further limiting their acid-making capacity.

In units consisting of a large number of small chambers the movement of the gas mixture is more rapid, mixing and impingement are caused by frequent passage from chamber to chamber, ratio of radiation surface to volume is higher and in some cases only 10 or 12 cu.ft. of chamber space per pound of sulphur per 24 hours is used.

Devices in Use for Cutting Down Chamber Space

We next observe the many schemes in which devices are used before, between and following the ordinary chambers for mixing the reacting gases, cooling them and providing wet surfaces for them to impinge upon. Among the better known of this class of process are the Gilchrist column, the process of N. P. Pratt, the Lunge plate tower and the ordinary packed "intermediate" tower. All these are effective and in some plants using them we find the total reaction space reduced to 7 or 8 cu.ft. per pound of sulphur. In general these processes aim chiefly at producing a more thorough mixing of the reacting gases.

A process which obtains faster reaction by means of high ratio of surface to volume and also by better cooling is that of Mills and Packard, so far used almost entirely in England. This process uses rather small lead chambers built in the form of frustums of cones, over the surfaces of which water is circulated. These plants have been operated using only about 4 cu.ft. of chamber space per pound of sulphur per 24 hours.

The rapid reaction attained in these chambers is probably due to unusual mixing, to the large amount of surface presented to the reacting gases and to the ability to use an unusually large proportion of nitrogen oxides in the gas mixture without raising the temperature of the chambers excessively.

Factors Influencing Reaction Velocity

A consideration of the facts briefly stated above, together with other phenomena of the niter processes, leads to these conclusions:

1. The velocity of the cycle of reactions between SO_2, O, water and the oxides of nitrogen, to form sulphuric acid, is greatly increased by vigorous mixing of the reacting gases.
2. The velocity of the cycle of reactions between SO_2, O, water and the oxides of nitrogen, to form

sulphuric acid, is increased by causing the gas mixture to impinge frequently upon wet surfaces.

3. The velocity of the cycle of reactions between SO_2, O, water and the oxides of nitrogen, to form sulphuric acid, is increased as the proportion of the oxides of nitrogen to the other components increases up to some proportion not yet indicated in commercial work.

4. In using proportions of nitrogen oxides appreciably greater than those used in well-managed chamber plants, it is necessary to provide means for controlling the temperature of the reacting gases more effective than simple radiation from the chamber surfaces to the surrounding atmosphere.

It was with these ideas in mind that the packed cell process was developed.

Details of the Packed Cell Plant

As the most effective practical means of causing vigorous mixing of the gases and at the same time providing a large amount of wet surface for cooling impingement and condensation, a column of acid-resisting brick was adopted. This is incased in lead or masonry and the reacting gases are driven through it by fans. The brick packing is so laid and the cross-sectional area is such that no unreasonable resistance to the passage of the required gas volume is offered. On account of structural considerations this packed column is built as a series of cells or towers.

It has been possible to design and build a plant entirely without lead chambers and consisting simply of a Glover tower, a set of packed cells and Gay-Lussac towers, to make acid at a rate corresponding to 1 cu.ft. of gross packed cell volume per pound of sulphur per 24 hours. When operating with a 7 to 8 per cent SO_2 gas, about 10 minutes is occupied in the passage of any given portion of gas from the entrance of the Glover to the exit stack. The plant which has been built and operated at Anaconda is shown in Figs. 1 to 7.

This plant operates on gas derived from roasting copper concentrate in a Wedge furnace. The gas is drawn from the furnace dust chamber through a 24-in. asbestos-covered steel flue, by a No. 11 Buffalo Forge "B" volume blower, provided with overhung runner, water-cooled bearings and a water-cooled gland where the shaft enters the case. The fan case is cast iron and the runner is of steel plate on a cast hub.

The fan forces the gas into the Glover tower, which is of standard design and dimensions. It is sheathed with lead and packed with Anaconda brick of standard dimensions. Two 4 x 4 x 4 ft. coolers receive and cool the outflowing acid. This division of the plant is just as would be provided for any chamber plant of equal capacity.

From the top of the Glover tower the gases pass

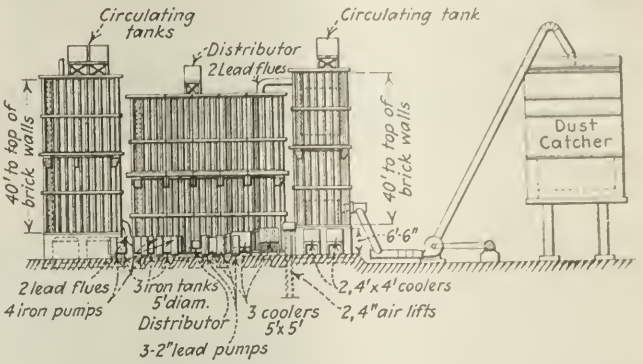

FIG. 2—ELEVATION OF 25-TON PACKED CELL PLANT AT ANACONDA

through a pair of flues to the packed cells. There are five of these packed cells built in one block and sheathed with lead. They are packed with acid-resisting brick of standard shape. The gas flow is down in No. 1, up in No. 2, down in No. 3, and so on. Experiment showed that there is no difference in efficiency whether the flow be up or down. Each cell is provided with its own acid-distribution system. The acid issues from the bottom of each cell into a launder and is conducted to the first of a set of three coolers in series. The cooled acid is pumped up to the distributing tank on top of the cells by a centrifugal pump. The gravity of the acid leaving the cells is maintained at such a point that it will take into solution neither SO_2 nor the oxides of nitrogen, that is 48 to 50 deg. Bé. This is accomplished by running water into the distributor boxes as needed. No water atomizers or steam are necessary. By varying the flows on the cells very close control of the gas temperatures can be maintained.

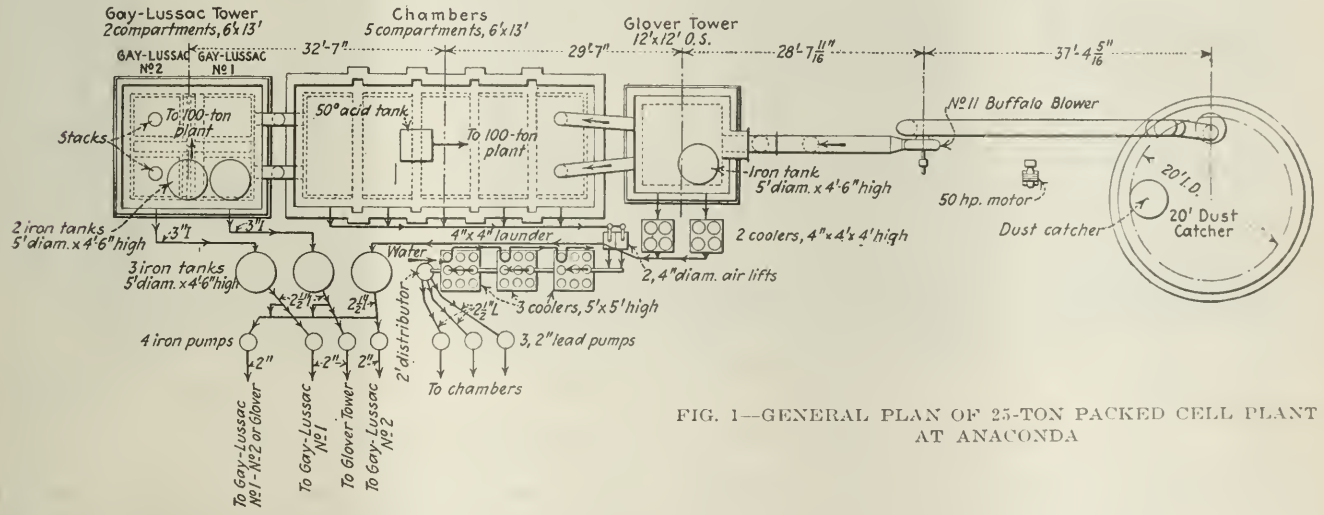

FIG. 1—GENERAL PLAN OF 25-TON PACKED CELL PLANT AT ANACONDA

Effect of Acid Concentration on Reaction Velocity

Some interesting data regarding reaction speed in towers using different acid concentrations were ob-

tained in the course of the experimental work. On account of conducting the burner gas a long distance, its temperature on entering the Glover tower was so low that it could not denitrate the nitrous vitriol fed, if the issuing acid was kept up to 60 deg. Bé. We ran for some time, therefore, with so large a quantity of 48 to 50 deg. Bé. acid and water going in with the nitrous vitriol that the issuing acid was only 50 deg. Bé. While this condition existed about 25 per cent of all the SO_2 entering the tower was converted to sulphuric acid. The Gay-Lussacs were meanwhile supplied with 60 deg. acid from the chamber plants. While operating in this way the plant was not, of course, an independent unit.

When the temperature of the gas entering the Glover was increased so that denitration could be accomplished with the issuing acid at 60 deg. Bé., the water was cut off and the flow of weak acid reduced. In other words, the conditions became normal Glover tower conditions. Running in this way, the tower converted to H_2SO_4 only 10 to 15 per cent of the SO_2 entering. This is the way in which the tower must be operated for the plant to be self-sustaining.

The experience indicates that the reactions progress more rapidly when the acid present is around 50 deg. Bé. than when it is around 60 deg. Bé., which is another way of saying when the nitrogen compounds will not exist in solution, but only in the gaseous condition.

There are two Gay-Lussac towers built in one block with an interior downtake flue between them, so that the gas flow is upward in both. These towers have masonry walls and are sheathed with lead. They are packed with standard brick.

The acid throughout the plant is pumped by Lewis vertical submerged centrifugal pumps with direct-connected motors. The pumps for the tower acid, which runs 60 to 61 deg. Bé., are of iron, and those for the weak acid are of hard lead and lead-lined iron.

A consideration of the principles of this process discloses the feasibility of using masonry walls instead of lead for the packed cells. This follows from the fact that the circulation acid in the cells provides for cooling so that radiation from the walls can be neglected.

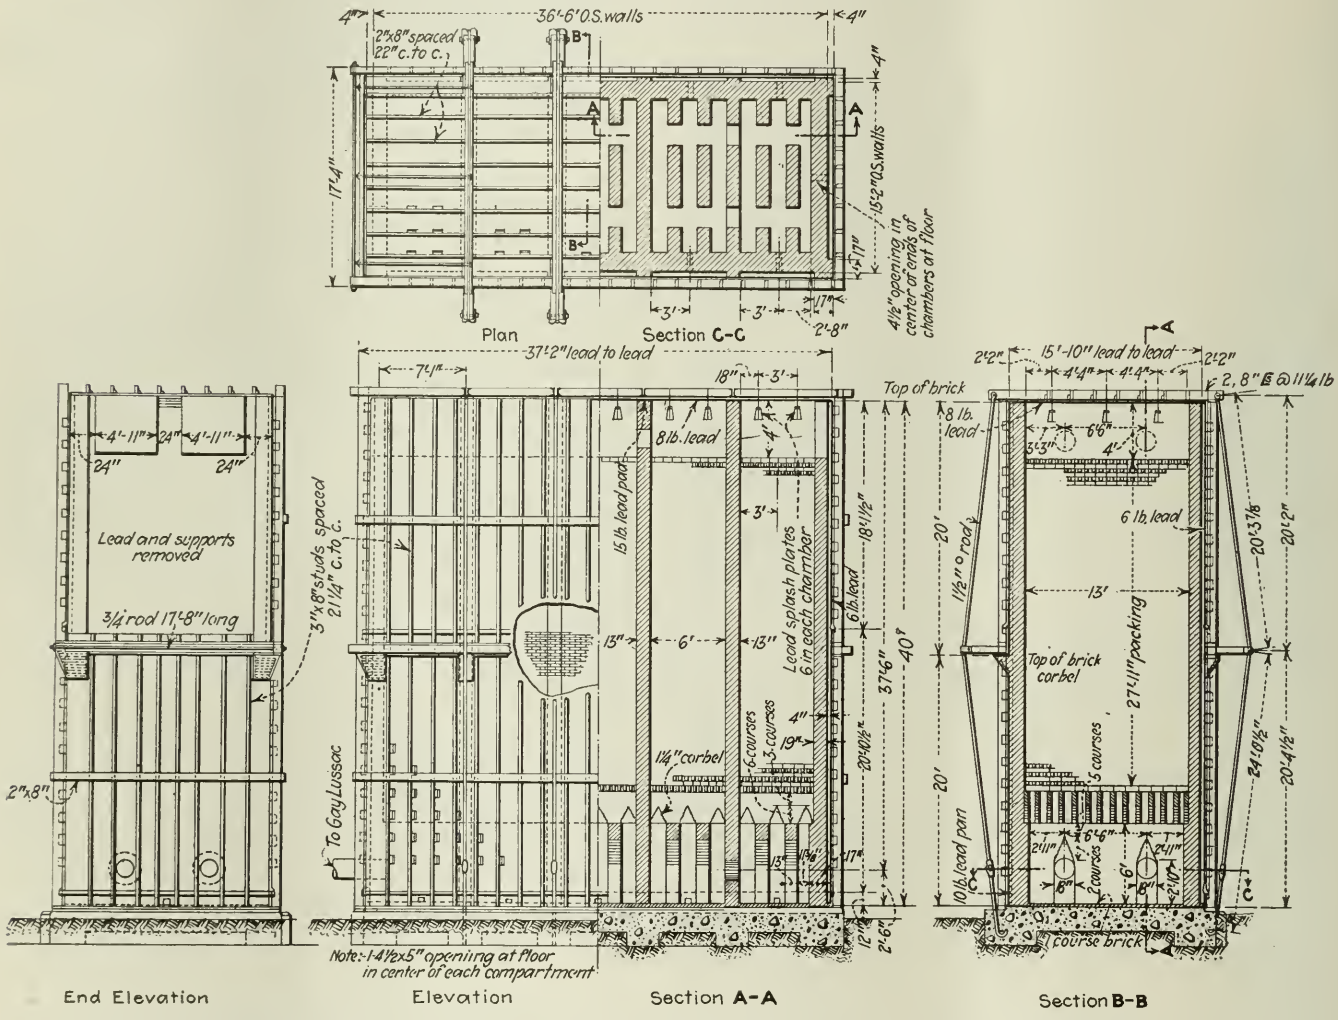

FIG. 3—DETAIL OF PACKED CELLS. 25-TON PACKED CELL PLANT AT ANACONDA

At the same time some rather contradictory reports and experiences as to acid-proof masonry being gas tight led to the decision to build, in the case of this pilot plant, the cells and the Gay-Lussac towers with masonry walls and to sheath them with light lead, thus assuring a tight plant with which to work out the operating details. After the plant had been operated for several months and satisfactory results and data had been obtained, a part of the lead sheathing was removed from the packed cell block. It was found that the masonry wall alone was quite tight and entirely satisfactory. A consideration of this structural aspect will be taken up later.

This plant was built in the winter of 1918-1919, upon

the basis of data obtained from experiments upon a smaller scale. It was put into operation about May 1, 1919, and operated without interruption until Oct. 1, at which time a lack of demand for acid necessitated shutting down. In the spring of 1920 the plant was run for about 6 weeks, when inability to dispose of the product again caused a shut-down. Since that time, conditions have not been favorable to a resumption of operation.

The source of SO_2 from which acid is made at Anaconda is three Wedge furnaces roasting copper cencentrate. This concentrate carries about 8 per cent copper and ranges from 32 to 40 per cent sulphur. The gas produced is somewhat irregular and ranges from 7 to 8 per cent SO_2. This set of furnaces furnishes gas for two chamber plants and for the packed cell plant. The niter consumption in the chamber plants is 4 per cent on the sulphur in the acid produced. In view of the irregularity of the gas and the fact that Anaconda is 5,300 ft. above sea level with a normal barometric pressure of 622 mm., a 4 per cent niter loss is not abnormal.

It is, in fact, comparable with 3 per cent niter loss in a plant burning brimstone and at a lower elevation. In considering the performance of the packed cell plant these conditions must be borne in mind and comparison in the matter of niter loss and production made with the chamber plants operating under the same conditions and not with a plant burning brimstone at sea level.

Performance of the Packed Cell Plant

The average daily production of the packed cell plant over a period of a little over 6 months was 20.3 tons of 60 deg. Bé. or 25.5 tons of 50 deg. Bé. acid. Direct figures on the yield in terms of acid produced per ton of sulphur burned could not be obtained because of the fact that all three plants were taking gas from the same battery of roasting furnaces. Very close control on the amount of SO_2 in the gas going to the Gay-Lussac towers was maintained, however, so that the yield was necessarily very high. The consistently low exit test is shown in the operating log, Table I.

The average daily niter consumption during the same period was 670 lb. of $NaNO_3$, or 6.6 per cent, figured on the sulphur in the acid produced. During the early part of the operation the niter consumption was around 8 per cent. This was consistently reduced as the operators became accustomed to the plant, and practice was improved so that during the last weeks of the run the niter loss was running about 4.4 to 4.5 per cent on the sulphur.

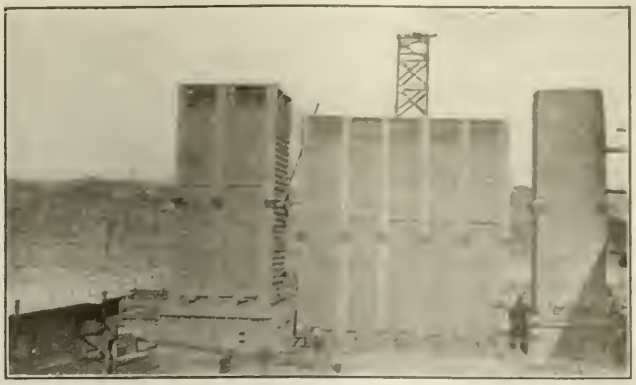

FIG. 4—25-TON PACKED CELL PLANT AT ANACONDA DURING CONSTRUCTION

Extensive tests were made to determine the character of the niter loss. These showed that about 55 per cent of the total niter in the stack gases could be absorbed by further contact with 60 deg. Bé. acid. It is quite certain, therefore, that by providing additional Gay-Lussac space, the niter loss in this process will be no more than that in a chamber plant operating under parallel conditions.

Comparison of Niter Rate in Chamber and Packed Cell Plants

A brief analysis of the niter recovery and loss figures of the packed cell process in comparison with the chamber process is in order. It has been mentioned that the unusual speed of reaction attained in the former is largely due to its ability to use higher than the ordinary proportions of the oxides of nitrogen.

In the usual chamber process the total amount of niter (nitrous vitriol plus fresh niter) introduced into the Glover tower, expressed in terms of $NaNO_3$, is 20 to 30 per cent of the amount of sulphur introduced in the same time. For example, if a plant makes 50 tons of 60 deg. acid in 24 hours, approximately 12.5 tons of sulphur as SO_2 is put in and there will be introduced as nitrous vitriol plus the gases from the pots, or fresh

SO_2 entering cell No. 1 determined by caustic absorption in Orsat.
SO_2 entering cell No. 5 determined by Reich test using N/500 iodine with acetate mixture.
Nitrosity of Gay-Lussac acids determined by titration with permanganate solution.
Pressure difference determined with Ellison differential draft gage.
SO_2 figures represent averages of tests made every 30 minutes. All other tests made hourly.
SO_2 in gas entering Glover is about 15 per cent higher than in gas entering Cell No. 1. Tests were made at latter point because the location was more convenient.

nitric acid, the equivalent of 5,000 to 7,500 lb. of $NaNO_3$. It has been found that niter in this proportion range will react with SO_2, O and water to the extent of converting substantially all of the SO_2 to sulphuric acid in from 1 to 2 hours, depending upon the construction of the chamber set. Such a gas mixture will develop sufficient reaction heat, with the sensible heat already in it from the burners, to produce in the front chambers temperatures approaching 100 deg. C.

If we attempt to make this set of chambers produce 100 tons of acid instead of 50 tons, it will be necessary to put through it twice as much SO_2 as before—i.e.,

FIG. 5—SIDE VIEW OF 25-TON PACKED CELL PLANT AT ANACONDA

assuming the same volume per cent of SO_2 in the gas, a given portion of gas will pass through the chambers in one-half the time it took when the plant was making 50 tons. In order to convert completely the SO_2 to H_2SO_4 in this reduced time, it will be necessary to substantially double the proportion of the nitrogen oxides, or to introduce in a given time four times as much as when the plant was making 50 tons per day. If this were done, we would find that due to the limited radiating capacity of the chambers the temperatures in the leading chambers would be too high for the proper reaction cycle and the process would work badly, with low yield and excessive niter loss.

In the packed cell process the ratio of sulphur to total nitrogen oxides introduced, in terms of $NaNO_3$, is about 10 to 7. In other words, where the chamber plant can rarely handle niter to the extent of more than 30 per cent of the sulphur, the packed cell plant can readily use 70 per cent, the reason being, as mentioned, the control of temperature afforded.

It should be clearly understood that the above figures do not mean new niter introduced—i.e., niter loss—but total niter, including nitrous vitriol.

In the chamber process operating at Anaconda under the same conditions, the total niter circulation is about 25 per cent on the sulphur and the niter loss is about 4 per cent. In the 50-ton chamber plant, for example, the sulphur input is about 25,000 lb., the total niter introduced about 6,250 lb. and the niter loss about 1,000 lb. per 24 hours. The loss, therefore, is 16 per cent and the recovery 84 per cent.

It will be readily seen that in a process using 70 per cent niter circulation instead of the customary 20 to 30 per cent, a much higher percentage recovery is necessary. If, for example, in a 50-ton-per-day plant we introduce the equivalent of 17,500 lb. of $NaNO_3$, which is 70 per cent of 25,000 lb., and wish to sustain a loss of only 1,000 lb., we must make a Gay-Lussac recovery of 94 per cent.

It is customary in chamber plants to provide from 125 to 175 cu.ft. of gross packed Gay-Lussac volume per ton of 60 deg. acid made. This amount gives ordinarily about the 84 per cent recovery mentioned. In the 25-ton packed cell plant under discussion the Gay-Lussac space provided is 213 cu.ft. of gross packed volume per ton of 60 deg. acid made. Total niter introduced amounted to about 7,000 lb. per 24 hours. Using the average loss figure of 670 lb., the recovery was 90 per cent. During the latter part of the operation, when the loss was about 460 lb., the recovery was about 93 per cent.

Niter was introduced into this plant in the form of mixed nitric and sulphuric acid, the production of which was described in a previous article.[1]

The question naturally arises why is it not possible in this type of plant to increase still further the niter circulation, decrease the volume of the packed cells and increase the Gay-Lussac space to get the additional niter recovery necessary. Perhaps this can be done to a limited extent. However, acid makers generally agree that there will inevitably be some niter going out the stack which is not soluble in sulphuric acid. Whether this be nitrogen compounds in a state of oxidation below NO or what not, it seems that between 3 and 5 per cent of the total nitrogen oxides introduced is not recoverable in Gay-Lussac towers. Somewhere, then, not far above the proportion carried in the present operation, an economic balance arises in the matter of niter ciculation beyond which it is not well to go.

Suppose, for example, a 95 per cent recovery of total niter introduced is all that we can recover even with

[1] "Introduction of Niter Into Sulphuric Acid Processes as Mixed Acid," by E. L. Larison, CHEM. & MET. ENG., vol. 26, No. 14, April 5, 1922, p. 642.

FIG. 6—END VIEW OF 25-TON PACKED CELL PLANT AT ANACONDA

greatly increased Gay-Lussac space. Assume that a niter circulation double that mentioned, or 140 parts of $NaNO_3$ per 100 parts of sulphur, be used. If 5 per cent of the niter be lost, the niter rate as $NaNO_3$ on the basis of sulphur will be 7 per cent.

A plant to operate with such niter proportions would need less cell space and more Gay-Lussac space than one using the 70 to 100 proportion and its cost would be almost the same. It is obvious, therefore, that the economic limit of niter circulation lies near that used in the present operation.

Power

The power used is all electrical, no steam or air being required. For pumping acid to the Gay-Lussac and Glover towers three centrifugal pumps were run continuously. The amount of acid fed to each tower was about 75 tons per 24 hours, so the total amount pumped was about 225 tons. These pumps are equipped with 5-hp. motors. The full capacity of these pumps is about 250 tons per day, so they were less than one-third loaded.

The acid for the cells was circulated by one centrifugal pump running continuously. The amount of acid fed to the cells was 250 to 275 tons per day. This pump is equipped with a 5-hp. motor and was pumping to full capacity.

The motor driving the draft fan used 20 hp.

Water

Water used for cooling the acid amounted to 50,000 to 60,000 gal. per 24 hours. It was not necessary at Anaconda to re-use the cooling water, but in case such procedure were necessary it would present no difficulties.

Labor and Maintenance

The plant was operated by one operator with one helper per shift. The operator made hourly observations and records of the SO_2 percentages of the gas entering the first and fifth cells, the nitrosity of the Gay-Lussac acids, the gravity of the Glover and cell acids and the draft gages. Operation of the pumps was entirely automatic. The helper had very little to do.

On account of the very compact nature of the plant and the fact that there are no actual operations to be performed (assuming that SO_2 is available as a by-product of the smelter) but simply regulation of acid and gas flows, a plant of any size can be operated by two men per shift.

The plant has not been operated long enough to require repairs of any consequence. The centrifugal pumps are very satisfactory. One pump of this type has been in use in one of the chamber plants for 3 years without any repairs whatever. So far as the operation has gone it seems reasonable to expect the general repair and maintenance costs to be smaller than those of a chamber plant.

Comparison of Costs

A general consideration of operating and repair cost figures on chamber plants and the packed cell plant at Anaconda leads to the conclusion that with plants of the same tonnage capacity the costs mentioned over a period of years will be at least equal for the two types of plant and probably lower for the packed cell type. In the matter of interest and depreciation charges the packed cell plant shows a very great advantage, since its first cost is so much less than that of a chamber plant.

The 25-ton pilot plant at Anaconda described and illustrated herein cost $68,066. It has been mentioned that the cells and the Gay-Lussac towers were built with both masonry and lead walls in order to assure a tight plant. The cost of the lead sheathing and its supporting framework on these two structures was $14,000. The cost of the plant without this precautionary sheathing was $54,000.

It is only fair also to say that at the time this plant was constructed, 1918-1919, material and labor prices were at a very high point. Some unit costs of the chief items of this construction were as follows:

Leadwork in place, per ton	$305
Brick in place in mortar, per thousand	52
Brick in place, dry, per thousand	27
Concrete in place, per cubic yard	17
Woodwork in place, per thousand	167

A considerable part of the lumber used was Douglas fir, which cost at the time $75 per thousand feet.

The experience gained in the construction and operation of this plant has made it clear that the cell and Gay-Lussac portions of future plants may be built with either the conventional lead shells and without masonry interior walls, or with masonry walls unsheathed. This latter construction has been demonstrated to be entirely satisfactory here in the Anaconda plant and at many other places as well. In designing future plants, therefore, it is necessary to ascertain the respective costs of the two kinds of construction and to use that one which is least expensive. The relative costs will depend largely upon the market price of lead, the freight haul and the cost of suitable brick- and mortar-making materials.

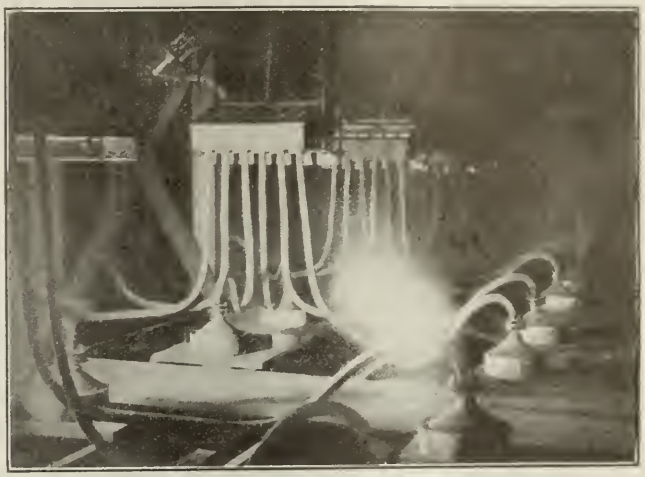

FIG. 7—ACID DISTRIBUTORS ON CELLS

At Anaconda the masonry construction is decidedly less expensive because bricks cost only $10 to $12 per thousand, and excellent ground silica costs about $3.50 per ton. Moreover, lead and steel are comparatively expensive because of the long freight haul. It may be said in general that when sheet lead and pipe can be laid down at the plant for 7c. and standard acid-proof brick for $25 to $30 per thousand, the cost of the two kinds of construction will be about equal.

Acid-Proof Brick Used at Anaconda

Some discussion of the brick suitable for this work is pertinent. For the past 5 or 6 years brick made from slime tailings produced in the concentration of the Butte ores have been used at Anaconda for tower walls and packing in the sulphuric acid plants here. This brick is entirely satisfactory for the purpose. The analysis of

the material is as follows: Silica, 74 per cent; iron, 1.6 per cent; lime, 1.1 per cent; alumina, 19.1 per cent; magnesia, 1.3 per cent.

The method of manufacture is simple. The slime is delivered to the brick plant containing varying amounts of moisture up to 22 per cent. It is fed into a rotary drier with a small percentage of sand, and the mixture is dried to about 15 per cent moisture. After being discharged from the drier the material passes through a set of conical rolls and thence into a pug mill. This machine, into which usually a little water is fed, thoroughly mixes the mass and delivers a homogeneous stiff mud. This mud is fed to an auger machine, which makes plain wire cut brick. After passing through a tunnel drier the brick are burned in an Oregon continuous kiln. No attempt is made to vitrify, and while the brick are hard and have a good ring there is no suggestion of a glaze.

Variations in Analysis of Satisfactory Brick

This Anaconda slime is, of course, of an excellent natural chemical composition. In order to show that considerable variations in analysis may exist between different grades of brick satisfactory for acid plant construction, analyses of two other bricks used in plants under the writer's observation are given herewith.

No. 1. A brick manufactured by an Eastern factory especially for acid work analyzes: Silica, 62.8 per cent; iron, 6.9 per cent; lime, 1 per cent; alumina, 23.7 per cent; magnesia, 1 per cent.

No. 2. A paving brick made on the Pacific coast analyzes: Silica, 64.8 per cent; iron, 4.6 per cent; lime, 3 per cent; alumina, 26.2 per cent; magnesia, 1.2 per cent.

With these analyses and several others in view, showing considerable ranges in the silica, iron, lime and alumina percentages, it seems fairly evident that in almost any locality satisfactory acid-resisting brick can be obtained at reasonable prices. It should not be assumed that any brick will do, because some brick, for chemical or mechanical reasons, disintegrated badly. Usually tests on crushing strength, weathering after saturation with acid, chemical analysis and general physical characteristics tell the acid engineer whether the brick is proper for the work.

The mortar used for laying acid-resisting masonry at Anaconda is made by mixing 30 deg. Bé. silicate of soda solution with finely ground Dillon rock, which is an almost pure natural silica. This mortar sets slowly, as the hardening is simply due to evaporation. It should be permitted to stand several weeks in an atmosphere as warm and dry as possible, in order that it may become thoroughly hard. After this set has taken place the masonry is sprayed or washed with sulphuric acid, which reacts with the silicate of soda to form silica and sulphate of soda. The mortar mass after this treatment consists of about 85 to 90 per cent of SiO_2 and 10 to 15 per cent $NaSO_4$ and water. In this condition it is practically unaffected by acid or water.

During the period of laying and hardening and up to the treatment with acid, acid-resisting masonry should be protected from rain or snow and kept as warm and dry as possible. This often means that during the construction of a packed cell plant of the masonry type a temporary shed must be constructed. In some cases when the climate and season are favorable only tarpaulin covers are required. In the case of the lead shell construction no such protection is necessary at any time.

Packed cell plants have been designed in 10, 25, 50, 100 and 250 ton capacities. In

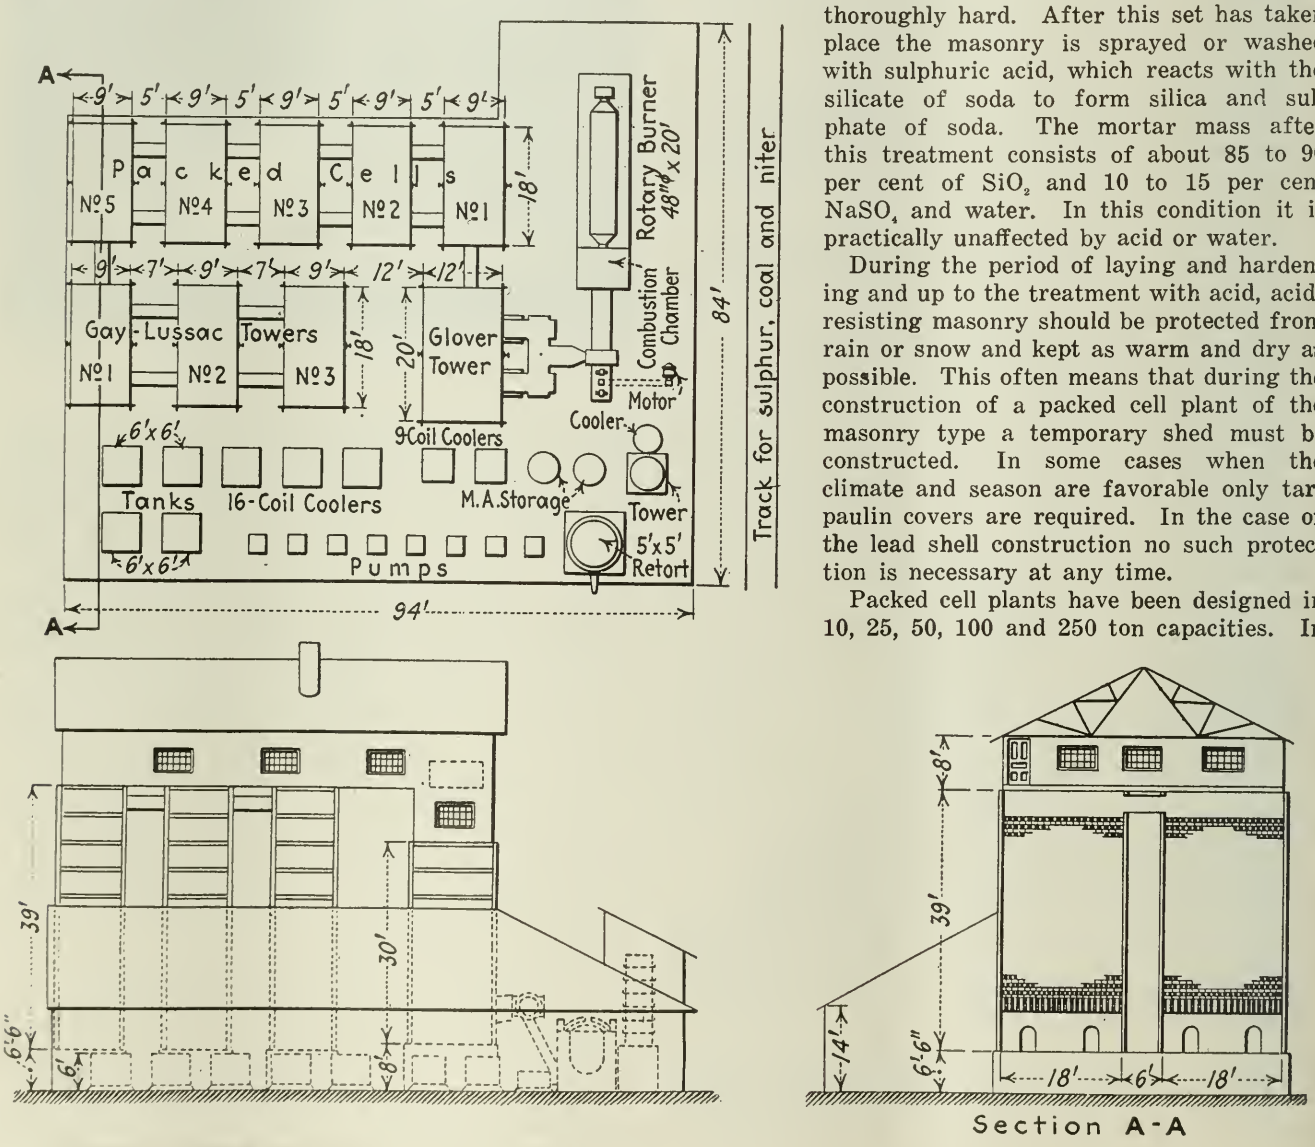

FIG. 8—GENERAL LAYOUT OF A COMPLETE 50-TON PACKED CELL UNIT OF THE LEAD SHELL TYPE

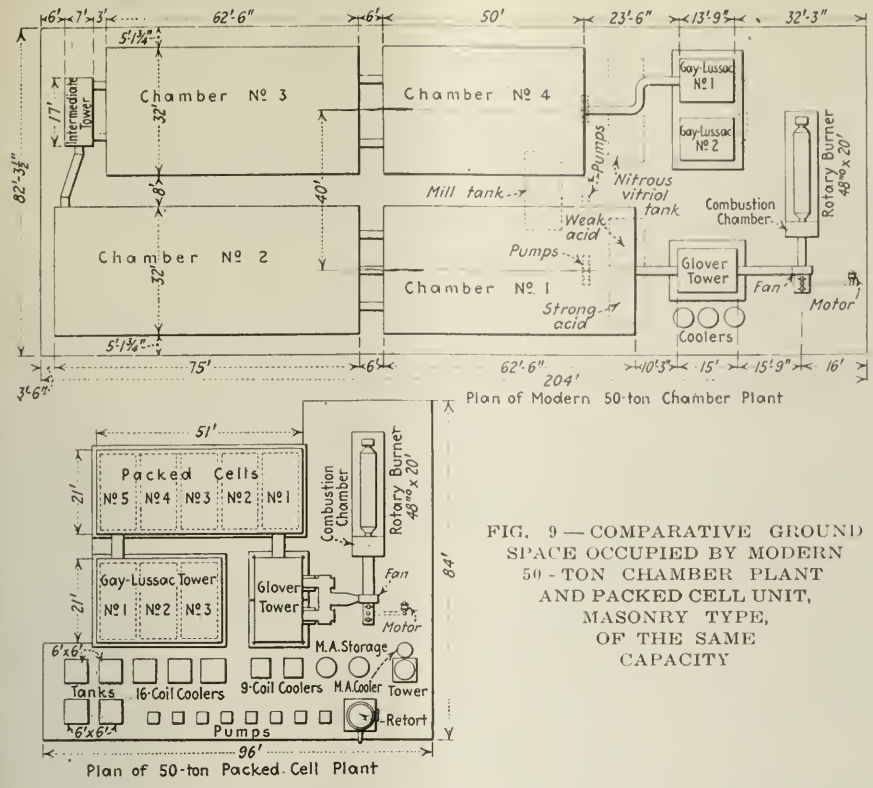

FIG. 9 — COMPARATIVE GROUND SPACE OCCUPIED BY MODERN 50-TON CHAMBER PLANT AND PACKED CELL UNIT, MASONRY TYPE, OF THE SAME CAPACITY

order to show the principal features of the plants as now designed Figs. 8 and 9 are shown of a 50-ton 60 deg. acid per day packed cell plant of brick construction and another of lead shell construction.

In Table II are given the relative costs of the two kinds of construction and the quantities of materials required for each.

Fig. 10 shows the relative ground space occupied by the packed cell plant of 50-tons-per-day capacity, and a modern chamber plant of the same capacity.

Comparative Costs of the Two Types of Packed Cell Construction

The chief advantage offered by the packed cell process is its low first cost. For example, a 50-ton 60 deg. Bé. acid per day plant can be built at present for something between $110,000 and $120,000, depending on local conditions. The cost of a chamber plant of this same capacity built in 1921 by one of the leading engineers in this country was approximately $220,000. This is a brimstone plant and the expenditure included the cost of the burner equipment. Another modern chamber plant completed in the early part of 1921 cost about $180,000 and has a rated capacity of 40 tons per day, which is in almost the same proportion.

If a chamber plant costs $220,000, produces 16,500 tons of acid per year, and is amortized at 12 years, the charge against the acid is $1.11 per ton. If the packed cell plant costs $120,000, produces 16,500 tons per year and is amortized at 12 years, the charge against the acid is $0.58 per ton.

With sulphur at $16 per ton, the cost of acid, including the amortization charge, is not far from $8.50 per ton of 60 deg. acid for the chamber plant of average size. For the packed cell plant this cost is about $8.

If the acid from each plant be disposed of to yield $10 per ton, the annual profit from the chamber plant on 16,500 tons is $24,750, which is 11.2 per cent on the $220,000 invested. The profit from the packed cell plant is $33,000 per annum, which is 27.5 per cent on the $120,000 invested.

This process is covered by Patent Specification 1,342,024.

TABLE II—COST ESTIMATES FOR 50-TON PACKED CELL PLANTS

	—Lead Sheathed—		— Masonry —	
	Amount Required	Cost	Amount Required	Cost
Excavation		1,000		1,000
Concrete @ $15	462 yd.	6,930	489 yd.	7,335
Brick in mortar @ $60	121 M.	7,260	346 M.	20,760

Total		$117,110		$114,165

The Mica Industry in 1921

The mica industry in 1921 on the whole reflected the general depression of business all over the country, according to a preliminary report issued by the United States Geological Survey. The decrease in the domestic output, sales and prices is marked and is not balanced by an increase in the imports. Several mica companies, especially in the South, were idle the entire year, and one large company discontinued business entirely.

Preliminary figures showing the quantity and value of mica sold in the United States in 1921 give a total of 3,854 short tons, valued at $174,838. Of this quantity 371 tons (741,190 lb.), valued at $117,989, was sheet mica; the rest was scrap mica. These figures are obtained from reports received by the Geological Survey from 97 per cent of the producers and others engaged in the mica business.

The production was made by eight states—North Carolina, New Hampshire, Virginia, New Mexico, Georgia, South Dakota, Colorado and Wisconsin, named in order of total value of mica sold from greatest to least.

The total quantity of uncut sheet mica sold in 1921 shows a decrease of about 56 per cent, and the value a decrease of about 78 per cent; scrap mica showed decreases of about 39 per cent in quantity and of about 66 per cent in value, as compared with 1920. Comparisons cannot strictly be made with any year previous to 1920, as the figures for those years include cut mica, or mica that has been through several stages of preparation for the market and thereby commands a higher price than uncut mica.

The average price per pound of all sheet mica sold in the United States in 1921 was 16 cents, as compared with 32 cents in 1920, and the average value per ton of scrap mica fell from $29 in 1920 to $16 in 1921.

Electric Steel Plant at the Southern Pacific Shops

Six-Ton Heroult Furnace Produces All the Steel Castings for the Large Western Railways as a Side Line —For a Year It Produced Rivet Steel From Miscellaneous Scrap, and Now Is Working on an Order for One Million Tie Plates

By LARRY J. BARTON

ONE of the largest railroad systems in the world, the Southern Pacific company, located its general shops at Sacramento, Cal., where it maintains large and well-equipped manufacturing and repair facilities. These shops have been in existence since the late '80s, gradually expanding to handle current needs. They now include practically every branch of industry necessary for the complete manufacture of all classes of locomotives and cars, besides being able to attend to the necessary repairs for other branches of the service such as steamboats and electric trains. A late acquisition is a steel-making shop, comprising a 6-ton Heroult electric furnace, with the necessary equipment for the making of ingots and castings.

Previously it has been the practice to collect old scrap, pile it carefully in bundles, wire the bundles tightly and send it to a small merchant mill owned by the railway company. Here these bundles were put into an oil-heated furnace, and when up to a good welding heat, were put under a steam hammer and worked down into compact billets. These were then reheated and rolled into the finished product. All sizes of small iron bars were made, together with flats up to 6 in. in width and 1½ in. thick. However, the steel pieces would never form a solid billet, due to the layers of oxide surrounding each piece; the method resulted in a large waste of split unsound bars and a product suitable only for low-grade work. Such work could scarcely be called steel manufacturing, and all steel for rivets, forgings or important members had to be purchased on the open market.

There were many ways in which a steel mill would be advantageous to the company shops, situated as they were, far from a large producer. Every year the road scraps large tonnages of wrought iron and steel of which only a small part was used in "fagoting," the remainder being sold on the market at whatever price could be obtained. Eventually this fell into the hands of different commercial steel companies, which remelted it and often resold it to the railroad company in the form of desired products, one of the highest priced being steel castings. It seemed reasonable on the face of this to suppose that if a small steel company buying scrap could furnish certain products at a given price, a resourceful plant using its own scrap could furnish the same product at an equal price or even cheaper, figuring the handling of the scrap as a saving.

With the proposal to build a steel plant accepted, there yet remained the question as to what sort of a melting furnace to install. Cupolas and converters, open-hearth furnaces and the electric furnace were very carefully considered from all angles.

For many years the company had been running its own iron foundry, and it was an easy matter to determine the average cost of molten cast iron in the ladle. The cost of blowing this metal to steel in the converter was then estimated, giving a final cost of the metal by this method. The question of quality then arose, and it was concluded that while converter steel would be suitable for the majority of cases, it would not meet several of the specifications requiring higher quality.

A small open-hearth was next compared to a 6-ton electric furnace. The electric process was chosen for several reasons:

Quality.—It is generally accepted that well-made electric furnace steel is superior to that made by either of the two processes before considered. This was an important point in the decision, especially when anticipating high class forging work for such products as gears, driving rods, crank pins, shafts and small axles, where a failure would tie up a locomotive and cost several hundred dollars per day in delays.

Cost.—Cost of the finished steel was, of course, the main deciding factor and was given the greatest consideration. It was figured not only for present conditions but for reasonably anticipated developments on the Pacific Coast in the near future. When this matter had been finally computed, it was found that the difference in the costs of the three proposed methods were very small, but a slight advantage was shown in favor of the electric furnace. High freight cost of Eastern pig iron militated against the converter. Inability to obtain "hot metal" for the open-hearth furnace militated against this process. There is no blast-furnace coke manufactured on the coast; furthermore, on account of the refractory nature of California iron ores, the erection of a blast furnace in this region is a very distant possibility. The present cost of electric power is rather low in comparison to the rest of the United States; this is likely to continue, since further great developments are under construction. That these factors were well weighted has been amply proved, since the electric furnace installed has turned out the highest grade of steel at a lower cost than it could be procured from several competing open-hearth plants, and has even melted gray iron for castings cheaper than the cupola.

Adaptability.—This point was so much in favor of the electric furnace that it scarcely needs discussion. Suffice it to say that the same furnace, without change of any kind, can economically make the following: steel castings; manganese steel castings; any required analysis of alloy and carbon steel for rolling or forging; iron castings, gray, chilled or white, of any analysis desired; malleable cast iron castings; special products such as acid-, fire-, and fume-resisting castings; special steels for magnets, electrical apparatus and trans-

formers. Not only these products came from the same furnace, but from the same general scrap, with only minor changes in the charge ratio. Furthermore, the temperature of the metal is under easy control (depending upon the time it is held in the electric furnace), making the furnace an excellent melter for either small, medium or large sized castings.

These were the salient points. An electric furnace plant needs a smaller floor space and lighter accessory equipment than the open-hearth; it is very easy to control accurately the chemical analysis of the resulting steel. An electric furnace also possesses an unexampled refining ability when working on low-grade scrap.

Acid vs. Basic Process

When the furnace had been installed another point arose as to whether we should use the basic or the acid process. The advantages for the acid process were a hotter steel, with a greater tonnage in a given period. Against this were the disadvantages that selected scrap must be used to meet specifications, due to the inability of acid bottom to eliminate any material amount of sulphur and phosphorus; specifications and analyses are harder to meet with constant exactitude; alloy steels cannot be very satisfactorily made, and can never be remelted to save high-priced alloys such as chromium and manganese; and finally power surges give more trouble than in a basic furnace. As the scrap to be used was high in phosphorus and sulphur, due to large quantities of wrought iron mixed in it, it was really imperative to use the basic process. Against the disadvantage of higher cost for this process were the ability to make any analysis with ease; great refining possibilities; easier power control; elimination of power surges and high peak loads; reclamation of alloy steel scrap; and most important of all for quality stock, complete de-gasification of the hot metal.

The furnace is located in an ordinary wooden frame building 130 ft. long by 65 ft. crane span, with a 30-ft. side bay on each side. The building, which was constructed in 1919, is higher than most steel foundries, which permits a ready exit of smoke and gas and makes excellent working conditions. This height was necessitated by building the furnace on a 10-ft. concrete platform in order to protect the ladle pit from any seepage of water, the shop being built on filled-in ground, once a marsh adjacent to the Sacramento River. The building is of the latest glass-walled construction, giving excellent light for molding purposes.

From the floor plan (Fig. 1) a very good idea can be obtained as to the general layout. The center bay is served by a 15-ton Champion crane. The shop was put in operation early 1920, and several improvements are now needed, such as another crane, a stripper and more floor room, all of which are expected to be made in 1922.

On the side floors are the bench molding, coremaking and cleaning departments, together with all like miscellaneous equipment. Directly in front of the furnace are the ingot pits. All ingots are plate poured (Fig. 2). Scrap is brought into the foundry on a standard gage flat car in large round buckets, containing about 2,500 lb. of such metal as old track scrap, forge butts, borings and turnings, forge flashings and clippings, all of which furnishes good material for the desired products. The furnace is charged by hand.

Operation of the furnace follows the standard two-slag process: eliminating phosphorus in the first, and finishing under a heavy carbide slag. The furnace is operated continuously and the results for the first 2 years have averaged 565 kw.-hr. per ton of charge, 33 minutes per ton of charge with the ordinary charge 7 to 8 tons in the ladle. Electrode consumption has averaged 30 lb. on carbon electrodes and 12 on graphite

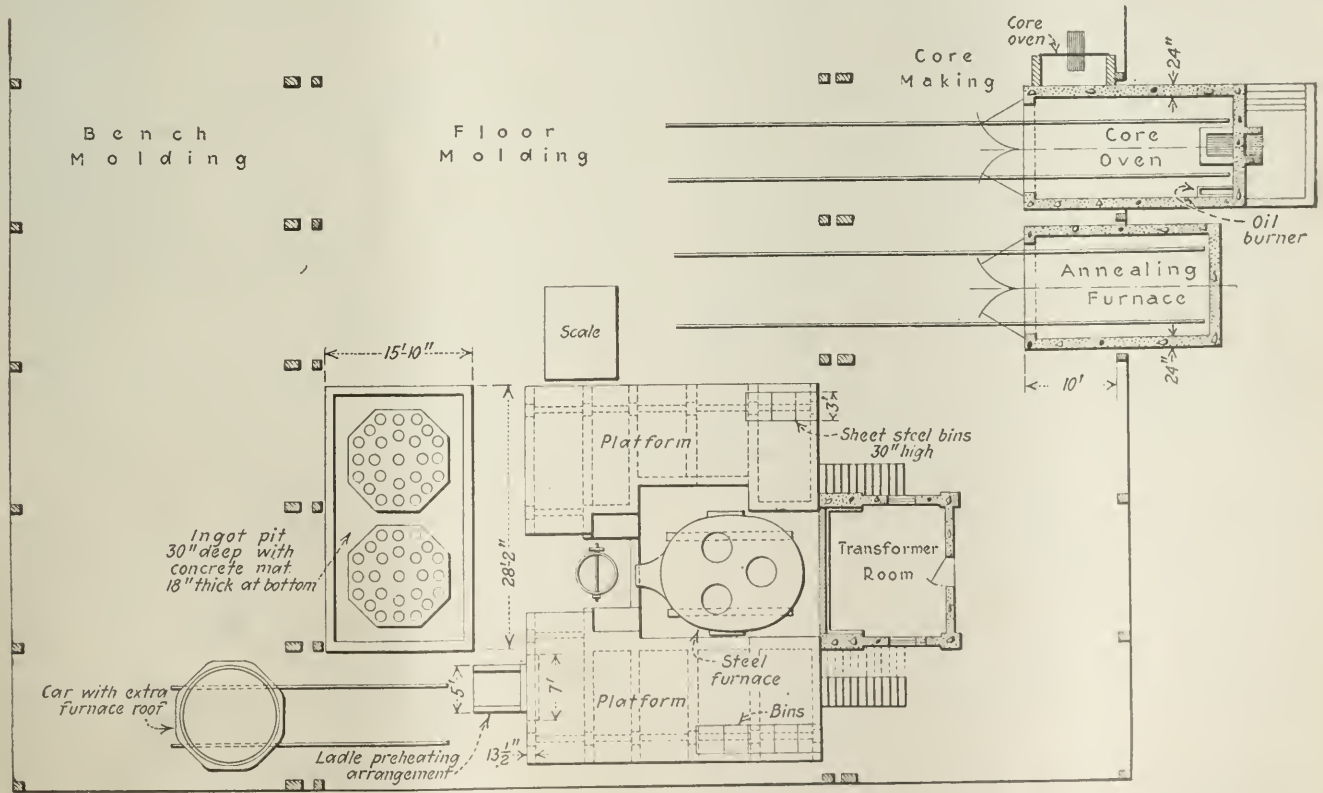

FIG. 1—GROUND PLAN OF STEEL FOUNDRY, SOUTHERN PACIFIC LINES

FIG. 2—TEEMING A NEST OF INGOTS. FURNACE IN BACKGROUND

per ton of product. The bottom was made of the highest grade of dead-burned magnesite and is still in good condition after 2 years of constant operation.

During the first year's operation the product went into rivet steel, plus about 30 tons of steel castings a month. Ingots cast were 6 x 6 in. in cross-section and 6 ft. in length, poured 20 to 26 on an octagonal plate, depending on the length desired. (A rectangular plate has now been installed so that the molds may be placed closer together and the combination be safer against runouts.) During this early period a large amount of forging ingots of varying sizes and composition were also made for stock, mostly 12 x 18 in. x 6 ft. ingots for main driving rods for locomotives. Crop ends and runners are rolled into bar iron for cheap material such as tie-rods or buckstays.

Early in 1921 several heats were made and cast in special ingot molds, rolled into tie plates and tested extensively to prove fitness and general adaptability. These proved so good that the shop was given an order to make 1,000,000 tie-plates, requiring about 9,000 tons of steel. Since that time we have specialized on this work and have made tie-plate steel and steel castings only. Tie-plate ingots are 9½ x 3½ in. at the bottom, 8½ x 2½ in. at the top, and 6 ft. in length, and weigh approximately 500 lb. As the small rolling mill owned by the company cannot handle pieces of this length, they must be cut in two, which is a costly operation, lacking heavy shears. To overcome this we are now experimenting with ingot molds 40 in. in length. So far the results are excellent.

Some physical tests made on the steel as rolled gave the following results:

Tensile Strength	Elongation Per Cent	Analysis C	Mn	Si	P	S	Cold Bend Test
77,840	25.0	0 25		0 34	0 066	0.041	1¼ in. round bent flat on itself, with no check
58,974	31.3	0.16	0.61	..	...	....	1¼ in. round bent flat on itself, with no check
112,000	12.5	0.48	0.96	0.25	0 057	.....	1¼ in. round bent flat on itself, no check
64,000	28.0	0 12	0 34	0.11	0.041	.....	1 in. rivet bent flat on itself, no check

The largest money maker for the foundry is steel castings. All steel castings used by the Southern Pacific Lines are made here, the foundry thus serving the territory from Portland to Los Angeles and as far east as Ogden. All classes of castings are made, including those for ferryboats, locomotives and cars, and those needed for general repair work on shop machinery. Their average size is about 150 lb., but sizes from 1 lb. to 16,000 lb. have been made. All small castings are stacked when poured, although an attempt is always made to get the small ones in a box with a large one, thus making an easier job for the ladleman and resulting in a superior product.

Due to lack of floor space and modern equipment the making of steel castings presents several difficulties. As many castings as possible are put into every flask, and it is interesting to shake out a locomotive frame with possibly twenty small-sized pieces sticking to it, like ornaments on a Christmas tree. All large cores are made at the iron foundry, several blocks away, and brought to the steel mill in small auto trucks, where they are set and dried by means of a gasoline torch. All dry sand molds are dried by small wood or charcoal fires, and are given finishing touches with the torch before closing. Most of the smaller sized work is made in green sand molds made of heap sand properly tempered with molasses water. The core sand mixture used is silica sand, one wheelbarrow; fireclay, two shovels; sawdust, two shovels; molasses water, one pint; molasses with water to suit. Dry sand molds are made of silica sand, one barrel; heap sand, one barrel; fireclay, five medium shovels; molasses with water to suit. Several brands of sand have been tried, but our present stock sand is made up of equal parts of Ottawa and Monterey beach sand and is excellent for all general classes of work.

Special Blank for Locomotive Frames

One type of casting which may be of interest is a special blank for locomotive frames. This piece is 10 ft. 5 in. long, 3 ft. wide, and 5 in. thick, with an auxiliary piece to increase the thickness to 6 in. From this blank it is possible to cut frame pieces for seven different types of locomotive. Its use results in a great saving of stock parts and always furnishes the necessary piece for a quick repair. We have poured this piece several ways, on the flat with heads at both ends, poured from the center; on the flat, poured uphill 18 in. from the bottom, with two large heads at the upper end; and on the edge from the center with four heads. The latter gives the best piece of steel.

We have also done quite a large amount of experimentation on the making of cast iron from steel scrap and find it both an easy and economical proposition. This has already been described in Chemical & Metallurgical Engineering for Feb. 2, 1922 (vol. 26, p. 270). Pig iron pays a freight rate of $17 a ton from the East by water and $22.40 a ton by rail. Add this to the cost f.o.b. furnace and then compare the sum to a conversion cost of from $12 to $16 plus scrap iron at $10! Under such conditions, synthetic cast iron is the logical source of metal for the iron foundry or for pouring castings direct.

From the general experience of the Southern Pacific Lines with the electric furnace, both from a standpoint of cost and quality, it is apparent to the writer that the future melter for the coast states, both for iron and steel, will be the electric furnace.

The System Furfural-Water—II

Mathematical Relations Governing the Concentration of Furfural From Its Solutions by Distillation—Practical Application of the Results of These Studies to the Problem of Recovering Furfural From the Dilute Solutions Obtained Commercially*

By GERALD H. MAINS
Color Investigation Laboratory, Bureau of Chemistry

FROM such a liquid-vapor, or solution-distillate, composition diagram,[15] as has been demonstrated by Lord Rayleigh,[16] the amount of distillate that must be collected in order to obtain any given portion of the furfural contained in the original solution can be readily calculated.

Following closely Lord Rayleigh's mathematical treatment of the subject, with only such changes as apply to this special case: Let w be the weight of solution remaining in the flask at any one time, and y the weight of furfural in the solution. The composition of solution, or abscissa, ξ, of the curve is $\frac{y}{w}$. As the distillation proceeds for a short time w becomes $w + dw$ and y becomes $y + dy$ (dy and dw being negative), and the composition of the vapor (or distillate), that is, the ordinate, η, of the diagram, is $\frac{dy}{dw}$. Thus

$$\xi = \frac{y}{w}, \quad \eta = \frac{dy}{dw} \tag{1}$$

The relation between the composition of solution and distillate as given by the curve may be expressed as

$$\eta = f(\xi) \tag{2}$$

$$\text{Now from (1)} \quad y = w\xi \tag{3}$$

$$\text{then } \frac{dy}{dw} = \frac{d(w\xi)}{dw} = \eta = f(\xi) \tag{4}$$

$$\frac{\xi dw + w d\xi}{dw} = f(\xi) \tag{5}$$

$$\frac{dw}{w} = \frac{d\xi}{f(\xi) - \xi} \tag{6}$$

$$\text{Whence } \log \frac{w}{w_0} = \int_{\xi_0}^{\xi} \frac{d\xi}{f(\xi) - \xi} \tag{7}$$

When the composition of solution, ξ, is small, say up to 3 per cent for furfural and water, the curve does not deviate much from a straight line. The relation may then be written

$$f(\xi) = k\xi \tag{8}$$

$$\log \frac{w}{w_0} = \frac{1}{k-1} \log \frac{\xi}{\xi_0} \tag{9}$$

$$\frac{\xi}{\xi_0} = \left(\frac{w}{w_0}\right)^{k-1} \tag{10}$$

That is, when a certain amount of solution is distilled off, the ratio of the final composition, ξ, to the initial composition, ξ_0, of the solution in the flask is proportional to some exponent, $(k - 1)$, of the ratio of the weights of the final and initial solutions, w and w_0, and this exponent is determined by the slope of the curve.

Calculating the value of k from the data for the lower portions of the curve, it will be seen that k is practically constant at 7.5 for solutions of less than 0.5 per cent furfural, and then gradually decreases. The value of k has decreased to 5.7 at 3 per cent furfural, beyond which concentration the curve deviates too far from a straight line to permit the use of equation (10) for any close approximation.

From these data the proportion of a dilute furfural solution of known strength which must be distilled over to secure any required fraction of the furfural can be determined. To illustrate: Given a solution containing 1 per cent furfural by weight, to obtain approximately 99 per cent of the furfural in the distillate. Using equation (10) and substituting values:

$$\frac{\xi}{\xi_0} = \left(\frac{w}{w_0}\right)^{k-1}$$

$$\frac{1}{100} = \left(\frac{w}{1}\right)^{6}$$

$$w = 0.464$$

$$w_0 - w = 0.536$$

Thus, by distilling over approximately 54 per cent of the original 1 per cent solution, the furfural concentration of the residual solution is reduced to 0.01 per cent. Nearly half of the water has been eliminated with a loss of less than 0.5 per cent of the furfural, and the concentration of the distillate has reached 1.84 per cent. By repeating this process with the distillate, it would be possible to obtain finally about 97 per cent of the original furfural and to eliminate practically all of the water simply by successive distillations. As the concentration of the furfural increases, the value of k becomes smaller and a greater proportion of the solution must be distilled over to obtain the same effect. Hence a very large number of distillations would be required and the process would be very tedious.

If it is desired only to reduce the concentration of the residual solution to one-tenth that of the original solution or to obtain about 90 per cent of the original furfural in the distillate,

$$\frac{1}{10} = \left(\frac{w}{1}\right)^{6}$$

$$w = 0.681$$

$$w_0 - w = 0.319$$

so that only 32 per cent of the original 1 per cent solution need be distilled over. Two-thirds of the water is thus eliminated, with a loss of only 6.8 per cent of the furfural, and at the same time the concentration of the distillate is brought to practically 3 per cent. Repetition of the distillations, each time reducing the concentration of the residual solution to one-tenth that of the initial solution, would eliminate practically all

*For Part I see CHEM. & MET. ENG., vol. 26, No. 17, p. 779, April 26, 1922.

[15]See Part I of this article.

[16]Lord Rayleigh, *Phil. Mag.* [6], vol. 4, p. 527 (1902).

of the water in seven or eight distillations, but would entail a loss of approximately 25 per cent of the furfural.

Table VIII gives the values of k for solutions up to 3 per cent, and the percentage of solution that must be distilled over in each case to reduce the concentration of the residual solution one-tenth or one-hundredth of the initial concentration.

Fractional Distillation

By using a somewhat different procedure the major portion of the furfural can be recovered from a dilute solution by comparatively few distillations. Use is made of the data here given to ascertain how much solution may be left in the still without appreciable loss of furfural. The distillate, however, which is constantly weakening during the distillation, is split into fractions.

Furfural solutions weaker than 1.5 per cent are brought up to that concentration by straight distillation, using the data given. When the concentration of furfural solution has reached 1.5 per cent the distillate from it will be approximately a 10 per cent solution, which will deposit a furfural later upon cooling to room temperature. This furfural layer is separated before any additional weaker distillate comes over to dissolve it. In this manner fractions consisting of wet furfural, saturated solution and two or more weaker concentrations are obtained. The weaker fractions are redistilled and their distillates distributed among the more concentrated fractions. Starting with a solution as dilute as 1 per cent and making use of this method, four or five distillations will usually suffice to obtain about 95 per cent of the total furfural in the form of wet furfural and saturated solution. The wet furfural can be practically freed from water in one distillation, and the small volume of saturated solution can be saved for combination with other lots.

The process just described is simply a mechanical approximation to the process carried out automatically by a fractionating column, and the use of a properly designed column will give a direct separation of wet furfural from dilute solutions in one operation.

Practical Applications

The question will arise as to the limitations in the application of the data here presented to the concentration of the dilute furfural solutions obtained in the commercial manufacture of furfural.

The preparation of furfural by the digestion of corncobs with 20 to 30 per cent sulphuric acid has given satisfactory results on a small factory scale in this laboratory. In co-operation with Dr. F. B. La Forge, the use of superheated water alone as a digestive agent is now under investigation. In France hydrochloric acid solutions have been used to digest kapok and other pentosan-containing materials for the manufacture of furfural. The hydrochloric acid process may be disregarded because of its commercial impracticability for producing furfural at a very low price.[17]

With the other two methods the condensed distillate from the digestion is a dilute furfural solution with the following approximate composition: furfural, 1 to 3 per cent; acetic acid, 1 to 2 per cent; acetone, 0.02 to 0.04 per cent; water 95 to 98 per cent, with small amounts of sulphuric and sulphurous acids carried over in the case of the sulphuric acid digestion.

The acetic acid may be separated by neutralization with lime before the distillation of the solution. This treatment, however, gives rise to much foaming during distillation, and it is better to recover the acetic acid from the residue after concentrating the furfural. The presence of the dilute acetic acid does not interfere with the distillation or separation of the furfural from the solution. Whereas acetic acid is carried over in the distillate, its concentration there is somewhat smaller than in the original solution and the greater part of the acetic acid is concentrated in the residual liquid in the still.

On the other hand, the acetone, although present in very small quantities, interferes somewhat with the separation of the furfural. It lowers the boiling point of the furfural-water system, and, being completely miscible with furfural, increases its solubility in the first portions of the distillate. During distillation the acetone portion comes off at slightly below 97 deg. C. and is a clear solution. When the temperature reaches 97 deg. C., the distillate becomes milky, owing to the separation of the furfural layer. When the temperature has reached 97.9 deg. C., the distillate will be practically free from acetone. The acetone portion must be removed as soon as the distillate appears turbid, and then concentrated separately. Although small in volume, it is rich in furfural. The remainder of the original solution behaves during the rest of the distillation simply as a pure furfural-water solution.

TABLE VIII—MATHEMATICAL DATA ON THE CONCENTRATION OF FURFURAL BY DISTILLATION

—Per Cent Furfural by Wt.— Composition of Solution ξ	Composition of Distillate η	Ratio: Comp. of Distillate to Comp. of Solution $\frac{\eta}{\xi} = k$	Per Cent to Be Distilled Off to Reduce Conc. to Given Fraction of Initial Conc. $\frac{\xi}{\xi_0} = \frac{1}{10}$	$\frac{\xi}{\xi_0} = \frac{1}{100}$
0.2	1.5	7.5	30	51
0.4	3.0	7.5	30	51
0.6	4.4	7.3	31	52
0.8	5.8	7.2	31	53
1.0	7.0	7.0	32	54
1.5	10.0	6.7	34	56
2.0	12.7	6.4	35	58
2.5	15.0	6.0	37	61
3.0	17.1	5.7	39	63

Traces of sulphuric or sulphurous acids cause no difficulty. If an appreciable quantity of sulphuric acid has been carried over during the digestion, however, it tends, upon being heated, to react with the furfural to form resinous substances, and should be partly neutralized.

Small quantities of furfural may be concentrated by several distillations as previously described, but in manufacturing furfural in large quantity an efficient fractionating column is essential. On the small-scale work at the Color Laboratory, making as much as 5 lb. of furfural a day, an ordinary copper column filled with porcelain balls has been used with fairly satisfactory results. For larger scale operations a special column is being designed.[18] Such a column will deliver three main fractions: *A*, containing acetone, furfural and water, boiling from 60 to 97.9 deg. C.; *B*, containing furfural and water, boiling from 97.9 to 100 deg. C.; and *C*, the remainder, boiling at 100 deg. C. and above, and consisting of water containing acetic acid and small

[17] Furfural is now being made in this country on a commercial scale by the Miner Laboratories, Chicago, Ill., but the details of the process are not available.

[18] Continuous furfural distillation apparatus, designed by the aid of the data presented, has just been placed in operation at the Color Laboratory. It has a capacity of 50 lb. of furfural per day when handling a 2 per cent solution.

amounts of formic, and perhaps sulphuric and sulphurous acids. The furfural layers are to be separated from fractions *A* and *B*, and the residual portions of these fractions continuously returned to the upper portion of the column. The crude, or wet, furfural obtained from such a column is purified by adding a small amount of sodium carbonate to the liquid, distilling, and, after the water has separated in the first portions, collecting the distillate coming over at a constant boiling point. This final distillation can also be conveniently carried out in a vacuum still.

Summary

The corrected boiling point of pure furfural has been found to be 161.7 deg. C. at 760 mm., and its density $D^{\frac{20}{4,\ Vac.}} = 1.1598$ and $D^{\frac{25}{4,\ Vac}} = 1.1545$. The composition-density tables at 20 and 25 deg. C. have been determined for solutions of furfural in water up to the saturation concentration.

Making use of these tables as a method of analysis, the mutual solubility curves at atmospheric pressure, and the boiling point and condensation point curves, or the liquid-vapor phase boundaries, have been determined for the system furfural-water.

The curve showing the relation between corresponding solution and distillate composition for dilute furfural solutions has been carefully determined with the elimination of errors due to partial condensation in the still head.

The mathematical relations for the distillation of mixtures as developed by Lord Rayleigh are discussed with reference to the case of furfural and water.

The application of these physicochemical data to the commercial concentration of the dilute furfural solutions obtained during the manufacture of furfural is discussed.

Sources of Thorium in Ceylon

Ceylon offers several possible sources of thorium, used in the manufacture of gas mantles, in the deposits of monazite sand, containing thorium, thoria, thorianite and raw thorite ore, or black thorium silicate, according to the report of Consul M. M. Vance from Colombo. Monazite sand was shipped from Ceylon in the amount of 72 long tons, valued at 40,000 rupees, in 1920. A British firm controlled the plant utilizing this particular deposit, and because of financial difficulties no shipments were made subsequently. Deposits of monazite sand are claimed to exist in practically every part of the Ceylon coast, and the Department of Mineralogy there is anxious to increase the market for the product and is willing to erect more machinery for extracting the thorium if successful in extending the market.

Thoria and thorianite have been offered in limited quantities at low pre-war figures, which will be furnished, together with the name of the person offering these minerals, upon application to the Bureau of Foreign and Domestic Commerce. Small samples of these two ores have been referred to the United States Geological Survey. The same merchant was reported as being able to furnish small quantities of what was thought to be thorite, or black thorium silicate, to purchasers in the United States. Thorite was formerly very generally used in obtaining thorium for gas mantles.

Investigation of Georgia Clays by Bureau of Mines

The kaolins and bauxites of Georgia occur principally in the coastal plain, the belt running diagonally across the state from east to west. The railroad lines of the Central of Georgia reach about 80 per cent of the white clays and bauxites of the coastal plain. The white clays are being mined at a few points, principally at Gordon, Claymont, McIntyre and Butler. These clays are sold principally to the filler trade. Bauxite mining has been carried on in the Cuthbert, Toomsboro and Andersonville districts and the bauxite is used principally in the manufacture of alum, abrasive and aluminum. The value of the clays and bauxites for ceramic purposes is little known. The investigation undertaken by the Ceramic Station of the Bureau of Mines, Columbus, Ohio, in co-operation with the Central of Georgia R.R., will consist in experiments to devise better refining methods and to test the physical properties of the different separations obtained. For this purpose a small-size refining plant is being constructed at the Ceramic Station.

Behavior of Clays Under Actual Working Conditions to Be Studied

This equipment is capable of handling from 500 to 1,000 lb. at a time. Evidently some of the clays will show promise of being valuable for pottery making purposes. After the laboratory tests are completed by the Bureau of Mines about 400 lb. of such clays will be taken into a commercial pottery and made up into pottery wares under practical working conditions, and the behavior of such clays as to working properties, color, percentage losses, etc., will be carefully studied. The white clays and bauxites of the coastal plain are closely associated, and this close association indicates that the bauxites were derived from the alteration of kaolins. Deposits are found which vary all the way from kaolin on the one hand to bauxite on the other. Some of these materials, which are higher in alumina than kaolin, show better refractory properties than No. 1 fireclays. Such clays, termed "bauxitic clays," undoubtedly would be most valuable for the manufacture of refractories superior to those now being made from fireclays. The refractory properties of such materials are to be studied, such as fusion temperature, load carrying capacity and resistance to spalling.

English China Clay Compared With Georgia Kaolin

English china clay is preferred to Georgia kaolin by many American potters. In comparing the two it is found that the English clay disintegrates in water more readily, produces a body which casts more satisfactorily, gives lower drying and bisque losses and requires less linseed oil to produce a spreading condition for oilcloth and produces a paper of better finish and more resistant to moisture. In preliminary work by the Bureau of Mines it was found that after calcining Georgia kaolin to low temperatures (500-600 deg. C.) it possesses properties similar to the English china clay—i.e., its adsorptive properties are decreased to that of the English china clay and the rate of capillary flow and the permeability of water is increased. Further tests are to be made to determine its commercial feasibility. The effects of aging the calcined clay in air and water are to be studied to determine how far the calcined clay will revert to its original state and also to study the varieties produced by different calcination tempers.

Reduction of Fuel Wastes in the Steel Industry*

By F. G. Cutler

IN ORDER to show the relative proportion of the energy in the shape of heat or power required for the manufacture of steel that is obtained from the fuel byproducts of the manufacturing process, the following figures have been prepared showing the quantity of heat derived from the byproducts of the manufacture of pig iron.

In the production of pig iron, from under 1,800 to over 3,000 lb. of coke is used. Part of the heat energy of this coke is required to reduce the ore to pig iron. Part is lost in radiation. Approximately one-half is available in the form of blast furnace gas. Most of this gas is used under boilers for the production of steam.

As blast-furnace gas leaves the top of the furnace it usually has a temperature of from under 300 to over 600 deg. F., generally averaging about 400 deg. F. At this latter temperature the sensible heat of the gas is equivalent to about 8 B.t.u. per cubic foot of gas at 62 deg. The B.t.u. per cubic foot of blast-furnace gas according to Brassert is $62.5 + 0.016R$, where R = lb. of dry coke per ton of pig iron; and including sensible heat of the gas at 400 deg. F. would be equal to $70.5 + 0.016R$. The cubic feet of gas per ton of pig iron (as shown by Brassert) is equal to $71.4R$, so that in the top gas from a furnace at 400 deg. F. the B.t.u. per ton of iron is $1.142R^2 + 5033.7R$. Brassert also gives the cubic feet of air per pound of coke equal to $51.4R$, so that both gas production and the blast requirement bear a direct ratio to the coke consumption of the furnace per ton of iron. The figures, so far as the author has been able to discover, are applicable to all blast furnaces using coke as fuel.

Heat Necessary for the Blast

The blast is heated in stoves under pressure, and the heat required per cubic foot of blast is proportional to the rise in blast temperature in the stove and inversely proportional to the efficiency of the stove, which is usually considered to average 60 per cent. After the necessary gas is used to heat the blast, the remainder can be measured in the shape of power.

The blast supplied from the blowing engines is heated by compression to about 150 deg. F., varying somewhat with blast pressure, etc., and is usually heated in the stoves to from 1,150 to 1,350 deg. F. In the following calculations it has been assumed that 0.02 B.t.u. is required per cubic foot of blast per deg. F., that the blast is heated in the stoves to 1,250 deg. F., that the average overall stove efficiency—i.e., ratio of heat given to the blast to the heat in the gas—is 60 per cent and that 55 cu.ft. of blast is heated per pound of coke charged.

The heat required in the gas for heating the blast for 1 ton of pig iron to a temperature of 1,250 deg. F. can therefore be expressed by the following formula where H = B.t.u. per lb. of coke burned in the blast furnace.

$$H = \frac{(1250 - 150) \times 0.02 \times 55R}{0.60} = 2020R$$

The heat in gas per ton product after the blast is heated is, therefore, $1.142R^2 + 3013.7R$. For other top temperatures and blast temperatures the constants will change slightly.

Boiler Horsepower-Hours Available

In 1 boiler horsepower-hour there is 33,305 B.t.u., and assuming that the "standard" efficiency of blast-furnace-gas-fired boilers is 66.6 per cent, in 1 boiler horsepower-hour $33,305 \div 0.666 = 50,000$ B.t.u. would be required in the gas, so that the boiler hp.-hr. per ton would be

$$\frac{\textit{Surplus B.t.u. per ton iron}}{50{,}000\ \textit{B.t.u.}}$$

As the blast-furnace product is usually expressed in tons per day, the average boiler horsepower per hour generated from blast-furnace gas under the above conditions can be expressed by the formula:

Average boiler horsepower per hour per ton of pig iron per day

$$= \frac{1.142R^2 + 3013.7R}{50{,}000 \times 24}$$

The following table shows the boiler horsepower-hours per ton of pig iron for several coke rates as calculated from the above formula:

Pound of Coke Per Ton	Boiler-Horsepower-Hours Per Ton Product	Boiler-Horsepower-Hours Per Ton Per Day
2000	211	8.8
2200	242	10.1
2400	276	11.5
2600	310	12.9
2800	348	14.5
3000	386	16.1

To furnish the blast to the furnace with either high-pressure condensing, turbo-blowers or reciprocating steam engines requires about 70 boiler hp.-hr. per ton of coke burned in the blast furnaces, and to operate the various furnace auxiliaries, such as pumps, air compressors, steam bells, mud guns, hoists, etc., requires from 15 to 25 boiler hp. per ton of product, so that after the furnace requirements have been met, there is available for the generation of power from 100 to 250 boiler hp.-hr. per ton of pig iron, depending on the coke burned in the furnace.

At 2 kw. per boiler hp.-hr., this means that from 200 to 500 kw.-hr. per ton of pig iron is possible with steam equipment from the surplus gas from the blast furnaces.

Heat Required in Steel Manufacture

The manufacture of steel from pig iron in the open hearth requires heat for melting scrap and fluxing the impurities, and power for the various operations incident to this process. The quantities of heat and power required vary materially with different plants on account of difference in equipment, practice, etc., but for the purpose of this paper it will be assumed that a ton of ingots requires 1 ton of pig iron plus enough scrap to offset the losses, and this work requires from 5,000,000 to 9,000,000 B.t.u. and an expenditure of from 20 to 30 kw.-hr. per ton. This ton of ingots will make about 0.85 ton of blooms, and the heating in soaking pits will require from 1,500,000 to 3,500,000 B.t.u. per ton of steel depending upon the temperature of the steel arriving at the pits, rate of operation, etc., and the rolling of the ingots into blooms will require from 40 to 60 kw.-hr. per ton. From the blooming or slabbing mill the material, usually reheated at an expenditure of from 2,500,000 to 6,000,000 B.t.u. per ton, is furnished to finishing mills, the power required, depending on the reduction of section, temperature of rolling, etc., varying from 35 to over 300 kw.-hr. per ton.

*Abstracted from *Mechanical Engineering*, April, 1922. Paper to be read at spring meeting, A.S.M.E.

TABLE I—HEAT BALANCE FOR MANUFACTURE OF 1 TON OF PIG IRON

From the coke plant delivering 1 ton of coke there result the following fuel byproducts for consumption in the steel plant after the heat and power requirements of the byproduct plant have been met:

12 gal. tar at 162,500 B.t.u. per gal., B.t.u.	1,950,000	
30 lb. of coke breeze at 12,000 B.t.u per lb., B.t.u.	360,000	
10,000 cu.ft. gas at 500 B.t.u. per cu.ft. (net value), B.t.u.	5,000,000	
Total per net ton coke		7,310,000
Heat available per ton pig iron	B.t.u.	B.t.u.
In tar from byproduct plant	2,435,000	
In coke breeze from byproduct plant	450,000	
In surplus gas	6,250,000	
Surplus from byproduct plant		9,135,000
In blast-furnace gas		19,635,000
Required for blast heating	5,000,000	
Required for blowing equipment	4,400,000	
Required for blast-furnace operation	1,000,000	
Required for total blast furnaces		10,400,000
Surplus from blast furnace plant		9,235,000
Total heat energy from byproducts		18,370,000
Heat required for steel plant		
Open hearth (pig iron to ingots)		
Melting (approx.)	7,000,000	
Power, 25 kw. at 25,000 B.t.u. per kw.-hr.	625,000	
Total heat consumption		7,625,000
Roughing Mill		
Heating (approx.)	2,000,000	
Power, 50 kw.-hr.	1,250,000	
Total		3,250,000
Finishing Mill		
Heating (approx.)	4,000,000	
Power, 100 kw.-hr.	2,500,000	
Total for finishing		6,500,000
Total heating requirements	13,000,000	
Total power requirements	4,375,000	
Total		17,375,000

Utilization of Industrial Wastes

Waste heat from open-hearth and heating furnaces and kilns is utilized for the production of steam, and otherwise waste steam is utilized in low or mixed pressure turbines for the production of power, but as these subjects have been discussed many times and are not peculiar to the steel industry, they will not be discussed except to say that while these economies are many times worth while in existing plants, very few new installations as designed include waste-heat boilers with furnaces, or low-pressure turbines as integral parts of new power plants.

Surplus byproduct gas, after the ovens are heated, is sold for use as domestic fuel, etc., replacing natural gas, water gas, etc., and is used in the steel plant for melting steel in the open hearth and for various heating operations in the steel industry. In former years this material was considered as having only nominal value and it was but rarely that any attempt was made to utilize it efficiently.

With the advance in fuel prices, shortage of natural gas, etc., and also largely due to special heating requirements connected with the manufacture of artillery and ammunition during the war, a number of combustion systems were developed that by more or less accurately regulating the proportion of air to gas have greatly increased the combustion efficiency of heating furnaces, and the control of combustion has been found of great importance in the maintenance of economy.

Dust coke breeze, from the coke plant—i.e., the material through a $\frac{3}{8}$-in. screen—is used to cover molten pig iron in transit from the furnaces and in making bottoms of soaking pits and heating furnaces. A great deal of this material which was thrown away or more or less inefficiently burned on hand-fired grates, or, by mixing with slack, on mechanical stokers, is now more efficiently burned by itself, on traveling-grate forced-blast stokers.

Tar, either before or after the creosote oils have been removed, has been found to be a very good fuel for open-hearth furnaces, either by itself or in conjunction with byproduct gas, and has been used for steam production either as an auxiliary fuel on blast-furnace boilers or by itself, and its use has been proposed to heat byproduct ovens, thus releasing additional gas otherwise required for heating the ovens.

Heat Balance

Table I gives an example of the approximate heat balance of 1 ton of pig iron as used in the steel plant, using average figures, and based on an average coke consumption in the blast furnace of 2,500 lb. of coke per ton of product.

Necessity of Heat Conservation

From Table I it will be seen that the total heat from the byproducts of a ton of pig iron is more than sufficient to finish the average ton of steel, but upon inspection of the table it will be found that the heating requirements have not been met from tar and byproduct gas, while the average power requirements are more than met from blast-furnace gas and coke breeze.

It therefore becomes very desirable to reduce the heating requirements for production of steel by using more efficient heating furnaces and to conserve all possible heat by charging hot steel into the soaking pit and reheating furnaces, in order to reduce the quantity of fuel required for supplementary heating.

The production of gas at the byproduct plant is practically uniform, while the consumption at the steel plant is variable and as a result the gas pressure at the steel plant (usually some distance away from the byproduct plant) is variable. As gas holders of sufficient capacity to absorb the fluctuations have not been found advisable, it becomes necessary to schedule the use of gas by consuming departments in order partly to equalize the consumption. In many cases it is advisable to use byproduct gas under boilers (although it is more valuable for other purposes) in order to prevent or reduce its waste, as it is easier to change from gas to coal on boilers than to fire up producers.

One of the most important problems of the steel plant manager and engineer is so to regulate the production and consumption of the various fuels occurring as a byproduct of steel-plant manufacture that the consumption of raw coal in producers or under boilers that would otherwise be sent to the byproduct plant is a minimum, for the reason that the byproducts from the coal, coked in the byproduct plant, usually exceed any possible return as fuel.

Japan Building Dye Industry

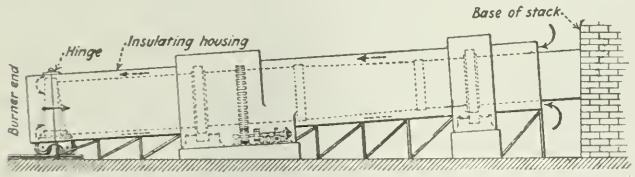
The *Indian Textile Journal*, December, 1921, is authority for the statement that the Japan Dyestuff Co. since its establishment has produced about one hundred different kinds of dyes, of which forty are already on the market. Some additional kinds are also to be put on sale, including scarlet for silk, water blue, pure indigo, acid brilliant red, and direct black 300 per cent. The last mentioned is claimed to be better than the American product. Moreover, the cost of production is said to be much less than in America.

Recovery of Radiated Heat From a Rotary Kiln or Drier

IN THE operation of a rotary cement kiln a quantity of the heat supplied is wasted to the surrounding air by radiation through the kiln shell. This has two undesirable results. First, there is a direct loss of fuel because of the extra amount necessary to make up for this radiation loss. Second, most kilns are located within a building, and the escape of this heat into the building makes working conditions trying and reduces the effectiveness of the workers.

There has been an attempt to eliminate these disadvantages by placing insulation between the brick lining of the kiln and the steel shell. This has not been entirely successful, for where high internal kiln temperatures are encountered the effect of heat on the brick lining must be considered. It is evident that if the heat loss from the brick is reduced, the temperature of the brick is increased. This temperature must not be permitted to reach the point which would reduce its life, yet sufficient insulation should be used to save the maximum heat possible. Kiln linings last only a short time at best, and the decrease of this time by such a misapplication of insulation is sufficient to condemn the method.

In seeking a means of recovering this heat without getting into other difficulties, Johns-Manville, Inc., suggests that the practical method is to surround the kiln with an insulated housing such as is shown in the accompanying sketch. This housing consists of an



HOUSING TO SAVE RADIATED HEAT

angle-iron frame around the kiln, covered with insulating material. The space between the insulation and the kiln shell is sufficiently restricted so that the velocity of the air drawn through this space is high enough to insure the heat being carried away, without increasing the shell temperature. Air is taken into this "live" air space at the open end of the housing, which is at the upper or entrance end of the kiln. It is then drawn through the housing around the shell and into the kiln at the delivery end, where it supplies the necessary air for combustion of the fuel.

Losses by Radiation in Cement Kiln

In developing this housing a study was made of the losses incurred through radiation. It was found that loss through the exposed surfaces of kilns often amounts to more than 1,000 B.t.u. per sq.ft. of surface per hour. Assuming continuous operation for 300 days or 7,200 hours per year, this gives a loss through each square foot of radiating surface equivalent to the consumption of 600 lb. of coal. As the heated air from the housing can be utilized in combustion of the fuel or in other ways so that about 90 per cent of the radiated heat is recovered, the saving in fuel can be made to amount to about 540 lb. yearly per sq.ft. When this heated air is used in place of cold air for combustion purposes in the kiln, conditions are bettered, as the fuel is not brought into contact with cold air which must be heated before combustion can take place.

The insulating housing can be provided with windows at any desired places in its sides, so that conditions within may be observed while the kiln is in operation. The comparative darkness within the housing makes it easier to notice hot spots in the kiln shell than if the kiln were located in the open. This enables repairs to be made to the kiln lining before the heat has damaged the steel shell.

Other Methods of Using the Recovered Heat

If it is not desired to use the heated air from within the housing for purposes of combustion in the kiln, it can be used in a number of other ways. For example, the clay used in the manufacture of some cements is dried before use, and the drier can be heated with this recovered heat. This use is advantageous in a plant where the heated air for kiln combustion is obtained from the clinker cooler. In other cases it can be employed for heating purposes, or such other uses as suggest themselves from plant conditions.

This method of recovery of radiated heat, which up to the present has been developed with rotary cement kilns in view, could well be applied to rotary and stationary driers and various types of industrial furnaces and kilns. In some of these applications the heat recovered would make an appreciable saving in fuel costs. In all cases where the equipment is located within doors general plant conditions could be improved by the reduction of the temperature in which it is necessary for men to work.

Manganese and Manganiferous Ores in 1921

The final statistics of the production of domestic manganese and manganiferous ore in 1921 are summarized by H. A. C. Jenison, of the U. S. Geological Survey, in the following tables:

MANGANESE ORE SHIPPED FROM MINES IN U. S. (EXCLUSIVE OF FLUXING ORES)

Mn Content of Ore, Per Cent	No. of Shippers 1920	No. of Shippers 1921	Gross Tons 1920	Gross Tons 1921	Value 1920	Value 1921
35 or more	56	14	94,420	13,531	$2,396,235	$495,097
10-35	31	6	357,279	8,439	1,450,518	$42,755
5-10	6	3	279,687	62,670	644,572	$147,576

MANGANESE ORE IMPORTED INTO THE UNITED STATES IN 1921*

Country	Quantity (Gross Tons)	Value
Africa	8,453	$27,198
Australia	.....	8
Brazil	262,468	1,952,848
British India	113,730	734,516
Costa Rica	588	17,658
Cuba	34	679
Honduras	14	140
Hongkong	7,319	131,052
	†392,606	†2,864,099

* Taken from records of the Bureau of Foreign and Domestic Commerce.

† About 8,700 tons, valued at $502,000, also reported as imports of manganese ore, but as the average value ranged from $46 to $128 per ton, these figures probably represent either spiegeleisen or ferromanganese.

Dyes From Kaoliang Bran

A method of securing dye from kaoliang bran has been discovered, according to a report to the Department of Commerce from Consul Kirjassof, Dairen. Kaoliang is a kind of sorghum, or giant millet, resembling broom corn. A mixture containing seven parts bran and the remainder consisting of soda, sulphate, etc., will produce the dye which is patented for brown and black, and also patent applied for to cover blue-black. Kaoliang bran may be obtained in practically unlimited quantities in Manchuria, delivered at stations of the South Manchuria Railway at approximately 1.80 yen per 100 kin.

Synopsis of Recent Chemical & Metallurgical Literature

Season Cracking.—In a voluminous paper[1] on "Testing Artillery Cartridge Cases," J. Burns Read and S. Tour state that season cracking, or corrosion cracking, of 70:30 brass cannot be predicted by chemical analysis, tensile or hardness tests or microscopic examination. Immersion in a 1.5 per cent mercurous chloride solution for 4 hours or in a 10 per cent mercurous nitrate solution for 15 minutes will open cracks in some articles. The authors believe that a season crack is the result of slow corrosion weakening the metal until its internal stresses exceed the tensile strength. Corrosion by mercuric salts produces accelerated "season" cracks probably by rapid and preferential amalgamation at the grain boundaries. While the test was vigorously opposed by manufacturers early in the war, the consensus now is that it is the most informative of all tests, both to indicate the quality of the finished piece and also to control the methods of manufacture.

Season cracking occurs in hard or soft pieces which are unequally strained in neighboring portions, and this strain can be removed by reheating to 500 deg. F. (260 deg. C.) for 1 hour, even though it causes no observable change in ordinary physical tests. Slight wear in properly designed tools may cause cracks by putting less work into one portion of the cartridge case than intended. Local strains caused by dirt and chips producing scratches on the metal will also cause season cracking.

Corrective measures vary, but some combination of the following usually suffices:

1. Increase the work during the last redraw, and anneal at the same temperature as formerly, if the increased tensile strength is permissible.
2. Increase the temperature or time of anneal if the lowered tensile strength is permissible.
3. Increase both work and anneal to relieve the strain without change in tensile strength.
4. Redesign the drawing and heading operations.
5. Use a final low-temperature anneal.

The last alternative is particularly effective and should be a matter of routine. The furnace could be heated by waste flue gas from other annealing furnaces, and the conveying done automatically.

Causes of Failure of High-Speed Tools.—A summary of an address by J. F. Kayser before the Birmingham (England) Metallurgical Society was printed in *Iron and Coal Trades Review* for March 31, 1922, p. 458. It is recalled that the method of failure depended in large measure on the shape of the tool; given a correct tool, however, there were two typical causes of failure: (*a*) abrasion of the chip furrowed the tool some distance behind its point, removing the support of the cutting edge which was later pushed away with the chip; and (*b*) up to time of failure there is practically no sign of wear, when suddenly the cutting edge is forced downward and into the lower part of the bar. These two types are found when doing both heavy and light work.

Inquiring into the belief that the "breaking-down temperature" was a measure of tool efficiency, tools of proved analyses were made, bored for thermocouple junctions, and provided with electrical connections whereby both the tool and the work could be heated. It was found directly that the cutting operation raises the temperature of both the work and the tool nose sufficiently to cause a pronounced change in their relative physical properties and the ability of the tool to cut the work was seriously affected. When the tool was first put to work there was a fairly rapid rise in temperature, quickly reaching a point where it remained constant until the moment of failure, when it again sharply increased. An annealed steel bar (Brinell 260) was mounted in a lathe, and a hot tool fed into it. With increasing temperature the cutting efficiency fell off, and at 500 to 550 deg. C. the tool refused to cut at all, even though the cutting edge was doubtless chilled by contact with the cold bar. However, if the work and tool were both at 600 deg. C., the tool readily cut for several minutes at a rate of 20 ft. per minute, $\frac{3}{8}$ in. deep and $\frac{1}{16}$ in. feed.

The Production of Gasoline by Cracking Heavier Oils.—The ordinary processes of refining crude petroleum yield a series of products differing widely in properties and commercial desirability. Cracking is already a factor of importance in the commercial production of gasoline. The experiments described in Technical Paper 258 of the Bureau of Mines, by E. W. Dean and W. A. Jacobs, issued in April, 1922, were not intended to cover the development of any one commercial process, nor do their results answer all the questions that arise concerning cracking. A number of important facts which do not seem to be generally recognized by those developing or operating cracking processes have, however, been demonstrated. The results of the experiments described in this report may be summarized briefly as follows:

1. Evidence obtained tends to support the theory that cracking is a contact-surface reaction, as the controlling temperature is that of the furnace walls rather than of the current of oil vapor.

2. (*a*) The range of temperature favorable for the commercial production of gasoline seems, for any given oil and any given pressure and rate of feed, to be within temperature limits considerably less than 50 deg. C. apart. With oil *A*, a distillate derived from Pennsylvania crude, the yields of gasoline at 550 deg. C. were probably a little lower than would have been acceptable in commercial practice. At 580 deg. the losses in recovery of cracked oil were excessive for commercial operations except possibly when the original fuel oil was exceedingly cheap or the plant was in a locality offering a profitable market for the gas formed.

(*b*) The favorable temperature range is apparently not the same for all oils and seemed to be at least 20 deg. C. higher for a Humble field, Tex., distillate (oil *D*) than for the Pennsylvania gas oil (oil *A*).

(*c*) The present experiments indicate that the degree of cracking possible with contact surfaces at 500 deg. C. or lower is negligible for the rates of feed employed.

3. Pressure is favorable for cracking, at least up to the highest limit (200 lb. gage reading) used in the present experiments. Limitations affecting the use of high pressure are apparently those imposed by the mechanical strength of the equipment rather than by the course of the reactions involved. It appears, however, that the advantage gained by increasing pressure from atmospheric to 100 lb. gage reading is notably greater than the advantage gained by a further increase to 200 lb. One hundred pounds is generally regarded as safe pressure for commercial size units, and fortunately seems high enough to yield a large share of the possible benefit to be derived from high pressure.

4. The quantity of carbon formed for the range of conditions favorable for gasoline production seems to be controlled chiefly by the content of high-boiling fractions, particularly so-called asphaltic material, in the oil cracked. Distillate oils deposit carbon in quantities too small to be measurable under present experimental conditions. It is believed that, in large-scale cracking operations, trouble with carbon can be obviated by using properly prepared oils, by controlling temperatures accurately, and, if necessary, by cleaning tubes occasionally by blowing out all oil vapor with steam and subsequently oxidizing any slight carbon deposit by a brief blowing with air. This latter treatment has been used in commercial sized vapor-phase cracking plants, and the present experience with light deposits of carbon indicates that it is probably efficacious.

5. On the assumption that a gasoline with an end point of approximately 430 deg. F. is to be produced, it appears that the vapor-phase cracking process can in a single treatment produce as much as 28 per cent of gasoline from a naphtha-free original oil. It is not believed, however, that this figure can be attained profitably in commercial practice, as it involves too great a loss in the recovery of

[1] *Transactions*, American Institute of Mining and Metallurgical Engineers, April, 1922.

cracked oil. It is not possible to predict what figure would prove most profitable on a commercial basis, but a yield of 20 to 25 per cent of gasoline seems reasonable and should not involve a loss in recovery of cracked oil exceeding about 15 per cent.

These figures are not impressive compared to those frequently quoted for the commercial possibilities of cracking processes, but it must be remembered that they mean a single treatment in the cracking furnace, that they exclude any naphtha that might be contained in the oil before cracking and that they are calculated on the basis of the oil originally run into the furnace instead of on the basis of the oil recovered. By taking advantage of various omissions in statement, it would have been possible to interpret present results as indicating gasoline yields as favorable as 45 to 50 per cent; but such figures, although imposing on paper, do not represent either an accurate scientific statement of results or the possibility of highly profitable commercial operations.

6. The losses in recovery of cracked oil, accounted for chiefly as gas formation, range from 10 per cent to 30 per cent. It seems possible to obtain commercially satisfactory yields of gasoline with losses not exceeding 15 per cent.

7. (*a*) The gasoline produced by vapor-phase cracking has a relatively high degree of unsaturation, the acid-absorption figures ranging from 25 to 40 per cent. The higher boiling fractions show a smaller acid absorption (lower degree of unsaturation) than the more volatile fractions. It seems, however, that the presence of olefine or unsaturated hydrocarbons is not essentially disadvantageous in the commercial utilization of motor fuel if certain associated products, probably diolefines, are removed. Such removal is undoubtedly possible and has already been accomplished in preparing Burton gasoline for the market, by properly regulated treatment with sulphuric acid. Hot filtration through Florida clay or bauxite is claimed (reference 22, p. 53) to accomplish the same purification.

(*b*) The relatively high specific gravity of some of the cracked products indicates an appreciable content of aromatic hydrocarbons. For gasolines that would be produced commercially, this aromatic content is not likely to exceed a maximum of 10 or 15 per cent and no evidence is at hand that this content is anything but advantageous.

8. The residuum from once-cracked oil does not seem to be quite as good for cracking as the original oil (see references 18 and 29). A higher temperature is probably required to bring about a desired degree of conversion, and unless the residuum is previously distilled to get rid of asphaltic, pitchy or other undesirable material, carbon trouble is likely to result. The Bureau of Mines has been advised that in one commercially operated vapor-phase cracking process no synthetic residuum is put back through the cracking furnace, the accepted practice being first to distill to dryness, then to crack the distillate. Another process of similar type passes the undistilled once-cracked residuum through the furnace, but distills it before attempting a second rerun.

9. Residuum fuel oils appear to be unfavorable material for cracking, the disadvantage, however, being excessive carbon deposition rather than failure to form gasoline. Some types of distillate oils seem to crack better than others, but no distillate oil was tried that did not seem to be satisfactory material for cracking.

10. It was shown that the recovery losses incident to a given percentage of gasoline formation were smaller when the temperature and rate of feed were relatively high than when these were lower. This seems to be a decided commercial advantage and is the reverse of what might have been expected on the basis of previous experience with cracking at very high temperatures.

Black Fractures and Graphitized Cementite.—Prof. W. Heike of Freiberg discusses "Reversed Chill and Similar Phenomena"[1] in *Stahl und Eisen*, March 2, 1922, vol. 42, p. 42. By reversed chill the author means the appearance of a rim richer in free carbon than the center of the casting. The name is derived from the fact that this is the reverse phenomenon to that encountered in chill castings where the surface is richer in combined carbon and poorer in free carbon than the center.

The author then describes specimens of iron in the museum of metallography at Freiberg. The first is a gray iron with a light colored rim and a dark center. The rim is composed of graphite, much ferrite, relatively little pearlite and steadite.[2] The center consists of graphite, pearlite and steadite, ferrite being absent. Apparently the formation of graphite has proceeded further at the surface than at the center. The second specimen, a black fractured steel containing 1.25 carbon and 0.80 silicon, has a dark rim containing temper carbon and a center consisting of pearlite and cementite without temper carbon. The rim is presumably due to a heat-treatment which the specimen has received.

Former investigators have attempted to ascribe reversed chill to a high sulphur or phosphorus content, or to oxides dissolved in the metal. Others have felt that the phenomenon is one of supercooling. None of these explanations seems to the author to be adequate.

Heike prepared two iron-carbon alloys from very pure material by remelting in a carbon resistor furnace. In these melts reversed chill was observed, even though sulphides and phosphides were not present in any significant amount in any of the materials from which the melt was made; nor was the graphite encountered in mottles after the fashion of temper carbon, thus controverting an opinion expressed by Bardenheuer.[3]

In iron-carbon alloys saturated with carbon and raised to high temperatures in graphite crucibles the author makes the unsupported assumption that iron oxide was not present dissolved in the iron. Thus he concludes that the opinion of Osann and others that oxygen is a significant factor is disproved.

Heike draws attention to a consequence of Le Chatelier's principle the application of which has apparently been overlooked—namely, "Every external influence arouses opposing forces in a system at equilibrium which strive to bring it back to its original condition." Pressure is the external influence not ordinarily considered in the equation

$$Fe_3C \rightleftarrows 3Fe + C$$

Since decomposition of cementite is associated with increase in volume, pressure should shift the equilibrium to the left—i.e., cause any free carbon to combine with iron and form cementite, thus decreasing the volume and relieving the added pressure, at least in part.

It follows that graphitization is opposed by any conditions tending to exert pressure upon the graphitizing material, or to exercise any constraint on the accompanying increase of volume. Chemical composition also plays an important part in graphitization, since graphitization accelerated by a high-silicon content—for example, when occurring in the outer layers of a casting—materially increases the pressure of these layers on the liquid or plastic center. Just how an increase in dimensions of the outer layers of a casting should exert pressure on the interior is not made clear.

Heike then refers to certain researches published by Ruer[4] regarding the formation of graphite directly from liquid iron and not from cementite. He dismisses these considerations with the statement that first the separation of such primary graphite occurs chiefly in very high-carbon alloys, and second that even though it occurred in the ordinary alloys, the separation of such graphite in the liquid must involve an increase of volume.

The author then proceeds to elucidate his thesis that the reaction $Fe_3C \rightleftarrows C + 3Fe$ will proceed only under such conditions where a material increase in pressure does not hinder it. He feels that this condition exists so long as a considerable part of the alloy is in a liquid condition. If, however, the metal has become completely solid through the freezing of the last residues of molten material, then the energy of the reaction is no longer sufficient to overcome the constraint exercised upon the equilibrium by the surrounding pressure, the possibility of expansion being there-

by limited or destroyed. He regards this explanation as also applying to the occurrence of cementite at the junction of several crystals in material otherwise consisting of graphite, ferrite and pearlite. He feels further that this explains why graphite formation is materially retarded in alloys relatively low in carbon, say between 2 and 3 per cent. He writes as follows:

"If we consider further the increase of volume occurring within the space of a single crystal as a consequence of graphitization, the pressure upon the still unfrozen part must increase as the freezing progresses. On the other hand, the casting as a consequence of its cooling shrinks in from the outside so that the last residue of molten material is subjected to a pressure which the graphitizing reaction can no longer overcome. In addition to external conditions the chemical composition of the iron is of consequence, inasmuch as it largely determines the energy with which the transformation of cementite into iron and carbon occurs."

Heike then shows that the location of the graphitic areas in these and commercial specimens corresponds to those areas in which compression stresses may be considered absent. No explanation is offered, however, why this phenomenon should not constitute the rule rather than the exception, nor of the peculiar occurrence sometimes noted in even the most carefully made crucible tool steel—that the axis has graphitized and the surface remains normal.

Recent Chemical & Metallurgical Patents

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Cooling Coke.—A series of three patents covering the principle and apparatus for cooling coke by steam (or other gases) and utilizing the water gas thus formed.

The first specification, 173,761, covers the arrangement of the cooling chamber, Fig. 1. The incandescent coke is conveyed from the distillation plant to a hoist by buckets *e* and the truck *q*, and is tipped into a fixed chute *i*, which discharges it into the dry cooling chamber *a* provided with an outlet *c*. The chute *i* is provided with a slidably movable lip *k* connected by a rope *l* to a lever *n*, which is connected by a pulley-guided rope *p* to a hood *d* which normally rests in a liquid seal and closes the inlet *b* of the chamber *a*. The lip *k* is thus retracted when the hood is down and projects into the opening *b* when the hood is raised, the lever *n* being operated by the bucket *e* in such a way that the hood is raised when the bucket is tipped. The rails *h* of the hoist are U-shaped in cross-section and bent over at the top, the lower roller *f* engaging the outer flanges of the rails *h* and the upper roller engaging the recess between the flanges.

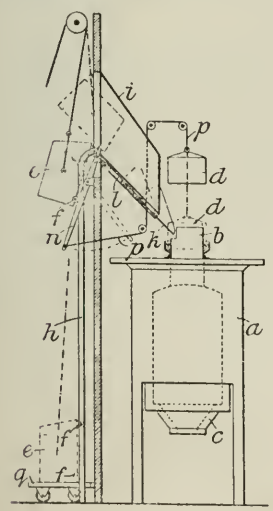

FIG. 1.

The second specification, 173,762, covers the process of cooling by means of a gas in the apparatus shown in Fig. 2. The coke is fed in known manner into a cooling chamber *a* and is cooled by a gas, preferably neutral, which is forced in a cycle through the cooling chamber and heat-exchange device. The gas enters the space *d* between upper and lower hoppers *c*, and ascends through the descending mass of coke. The lower hopper *c* is provided with slides which regulate the outlet and are symmetrically arranged always to form an outlet directly below the baffle plate *f*, which prevents the central core of the mass from descending too rapidly. As shown, forked slides *h* are used which are operated by right and left handed screws *i*. A door *g* is provided mounted on rollers *k* and is movable on rails *l*, which are pivoted at *m*, their free ends being vertically adjusted by toggle sleeves *o*. The cooling of the coke is effected progressively from the bottom, the lower layers being cooled and discharged gradually while the top layers are still incandescent, the fresh coke being added gradually.

The third specification, 173,763, covers the use of steam for cooling the coke in the apparatus shown in Fig. 3. In

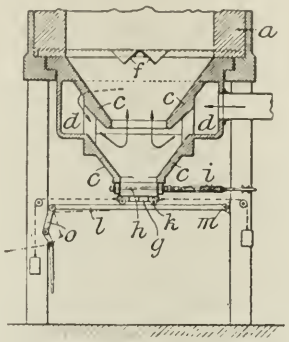

FIG. 2.

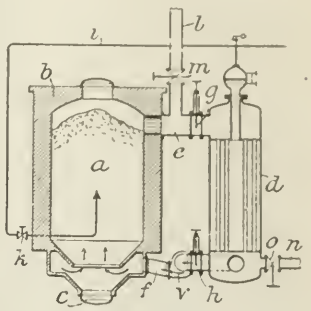

FIG. 3.

this process, the heat contained in the coke when it is below the temperature at which water gas is formed—namely, 600-700 deg. C.—is utilized to produce the necessary steam. The incandescent coke from the retorts passes through the cover *b* into the chamber *a*, which communicates by pipes *e*, *f* at top and bottom with a steam generator *d*, valves *g*, *h* being interposed and a blower *v* being provided to circulate the gases in the chamber *a* through the steam generator *d*. Steam is supplied to the coke mass through a pipe *i* and valve *k*, the water gas being withdrawn through a valve *m* and pipe *l* or, if it is desired that the heat of the water gas should be absorbed in the steam generator, through a valve *o* and pipe *n*. The first charge is cooled entirely by the blower *v*, thus producing steam for subsequent charges. The cooled coke is discharged at *c*.

Tanning.—Instead of using iron formate for tanning hides, as described in the parent specification, a tanning material made by partial double decomposition between an iron salt and a formate is used. Examples are given of associations of ferric chloride and ferric sulphate in excess quantities with calcium and sodium formates. Calcium sulphate when formed is filtered off. Sodium chloride is allowed to remain in the liquor as an aid to tanning. In one example 10 kilos of ferric sulphate dissolved in water is treated with 2.5 kilos of calcined sodium carbonate at 30 deg. C., 4 kilos of solid calcium formate being stirred into the liquor after cooling to 25 deg. C. (Br. Pat. 173,853. Chemische Fabriken Worms Akt. Ges., Frankfort-on-Main, Germany. March 1, 1922.)

Decolorizing Carbon.—Carbon for purifying and decolorizing purposes, and especially adapted for filtering, is made from vegetable material of fibrous structure and not containing much inorganic matter, by carbonization in the closed retort with the injection of gas or steam. The product is ground in a dry state to a degree of fineness short of that at which the fibrous structure is obliterated. In an example, pine wood in a granular state is heated to about 400 deg. C. for 6 hours or less, the gaseous products being evacuated continuously. The temperature is then raised to 1,200 deg. C. for 6 hours or more, and superheated steam is passed in. In the third stage, a temperature of 1,500 deg. C. is maintained for 3 hours without injection of gas, or with injection of nitrogen. The product is ground in a ball mill using steel balls until it almost all passes through a sieve of 20 to 30 mesh, but rests on a 90-mesh sieve. (Br. Pat. 173,624. J. N. A. Sauer, Amsterdam. Feb. 22, 1922.)

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Strong Technical Program Announced for Chemical Engineers' Meeting at Niagara

Important papers on acid manufacture and nitrogen fixation will feature the technical program of the fourteenth semi-annual meeting of the American Institute of Chemical Engineers, which will be held at Niagara Falls, Ont., June 19 to 22, 1922. The general headquarters for the summer meeting will be at the Hotel Clifton, one of the leading hostelries on the Canadian side of the Niagara River. Special automobile and boat trips have been arranged and one entire day will be given over to sightseeing and plant visits in Toronto. A similar trip to Buffalo on the following day will include business and social sessions at the Hotel Lafayette.

An interesting program has also been arranged for the wives and guests of the Institute's members. Sightseeing trips, theater parties and afternoon teas have been substituted for the technical and business meetings of the members. The ladies' program is in charge of Mrs. A. H. Hooker, chairman for Niagara Falls, and Mrs. C. B. Morey, chairman for Buffalo.

G. Prescott Fuller, chief chemist of the National Electrolytic Co., is chairman of the executive committee. The vice-chairman is C. B. Morey, manager of the soap department of Larkin Co., Inc. Finances are under the direction of David H. Howard. The chairman of the Toronto committee is Prof. J. Watson Bain of the University of Toronto.

The members of the principal committees are as follows:

Buffalo Committee—C. B. Morey, *chairman;* C. C. Heriage, J. D. Kerr, W. L. Spalding, H. J. White, E. G. Rippel and D. H. Howard.

Niagara Falls Committee—G. P. Fuller, *chairman;* T. L. B. Lyster, H. W. Kellogg, Max Mauran, F. A. Lindbury, F. J. Tone, R. C. Snowden, and E. M. Sergeant.

Transportation arrangements have not yet been announced, although it is possible that a special trip by boat and train will be arranged for the benefit of members residing in the New York district. A number have expressed their desire to make the trip by automobile and the Institute's secretary, Dr. J. C. Olsen of Brooklyn Polytechnic Institute, is arranging to organize these into special parties to follow a definite route and schedule.

The principal features of the detailed program follow:

MONDAY, JUNE 19

Meeting at Hotel Clifton

Registration.

9:30 a.m. Papers:

"Thermal Considerations in Sulphuric Acid Concentration," F. C. Zeisberg.

"Modern Methods of Concentrating Sulphuric Acid, Including Concentration of Sludge Acid and Acid Proof Masonry Construction," P. S. Gilchrist.

"Increased Capacity of Cascade Systems," Dr. L. A. Thiele.

"The Solubility of Quartz Packing in the Glover Tower," L. J. Michael and J. R. Withrow.

"Sulphur Dioxide and Fume Problems and Their Solutions," Dr. P. J. O'Gara.

2:15 p.m. Automobile trip, Niagara Falls, Ont., including new power canal and inspection of Niagara Falls plant of Hydro-electric Commission.

8 p.m. Public Lectures, Hotel Clifton:

"Geology of the Niagara District," John Jackson.

"Niagara Power Development" (illustrated), John L. Harper, chief engineer Niagara Falls Power Co.

TUESDAY, JUNE 20

Special cars leave for Lewiston at 9:30 a.m. via the Gorge route on the American side. The boat is taken for Toronto at 10:30 and after business session and luncheon aboard, the party disembarks at 1 p.m. and the afternoon is spent in sightseeing and plant visits. The return boat leaves Toronto at 5:25.

WEDNESDAY, JUNE 21

8:30 a.m. Special cars for Buffalo leaving Hotel Clifton.

9:45 a.m. Meeting at Hotel Lafayette: Papers:

"Manufacture of Nitric Acid," Arthur Hough.

"Manufacture of Hydrogen and Nitrogen for Synthetic Ammonia Manufacture," H. S. Taylor.

"Some Economic Aspects of Ammonia Oxidation," Dr. G. B. Taylor.

"Muriatic Acid—Saltcake Industry," P. C. Kingsbury.

"Vapor Tension at Low Temperatures," N. T. Bacon.

2:15 p.m. Automobile trip and visits to Buffalo plants.

8 p.m. Smoker, Hotel Lafayette.

THURSDAY, JUNE 22

9:30 a.m. Meeting at Hotel Clifton. Papers:

"Production of Hydrochloric Acid for Chlorine and Hydrogen," Hugh Kelsea Moore.

"Tank Cars for Transportation of Muriatic Acid," J. M. Rowland.

"Manufacture of Phosphoric Acid," Dr. P. E. Landolt.

"Manufacture of Phosphoric Acid," Theodore Swann.

"Recent Advances in the Production of Phosphoric Acid for Fertilizer and Food Purposes," W. H. Waggaman.

"Value of Water-Soluble Phosphates," Milton Whitney.

Automobile trip at 2:15 p.m. and optional visits to plants at Niagara Falls, N. Y., followed by a complimentary tea at the Niagara Falls Country Club.

Explosibility of Synthetic Ammonium Nitrate Subject of Study by Bureau of Mines

Upon the recommendation of the committee on the investigation of the explosibility of ammonium compounds of the National Research Council, the Bureau of Mines will undertake an investigation of the explosibility of synthetic ammonium nitrate by boosters on small scale. The work of the committee has for its general purpose the investigation of the explosibility of ammonium compounds, but the Bureau of Mines portion of this, as now proposed, is limited to (*a*) small-scale tests with charges not to exceed 10 lb.; (*b*) that particular ammonium compound designated ammonium nitrate; (*c*) that particular ammonium nitrate which is customarily transported and stored as such outside of powder factories—that is to say, imported synthetic ammonium nitrate. This new investigation is to be conducted on samples at normal temperature, at normal density and a definite but as yet unstated confinement, and the criterion of explosibility is to be the compression of small lead blocks.

Butterworth-Judson Receivers Organize

Receivers for the Butterworth-Judson Corporation, manufacturer of chemicals and dyestuffs, with a plant at Newark, met on April 24 at the offices of the company, 30 Church St., New York City. They are Thomas G. Haight and Henry G. Atha, Newark, and James O'Grady, Scarsdale, N. Y. No statement was given out after the meeting, but it is understood that a plan will be worked out later for carrying on the business of the firm.

Tariff Discussion Opens in Senate—Opposition to Dye Embargo

Discussion of the tariff bill has occupied most of the time of the Senate since April 20. The leaders of each party have outlined the general course their arguments will take. With a couple of exceptions specific rates have not yet entered into the debates.

Initial discussion of the tariff bill in the Senate reveals that there is practical unanimity of opinion in that body that the ad valorem rates in the bill should be based on a valuation made in the country of origin. Sentiment in the Senate seems to be as strongly opposed to American valuation as that of the House is in favor of it. Approximately 60 per cent of the commodities covered by the dutiable list take ad valorem rates. The remainder of the articles on the dutiable list are covered by specific rates. Every effort was made by the Finance Committee to apply specific rates wherever possible. The difficulty is that specific rates are impracticable in many cases.

Many Senators are in favor of passing over American valuation without dignifying it by discussing the plan in the Senate. It seems probable, however, that it will be necessary to debate the whole subject, as the bill reported to the Senate provides for the application of American valuation if the President should deem it necessary.

Chairman McCumber, of the Finance Committee of the Senate, agrees that of all times in our history this is the very worst to formulate and put into effect a new tariff measure, but he declares there never has been a time when it is more necessary to protect American industry against abnormal situations abroad which give special advantage to the foreign producer. He points out that wages in Germany declined enormously immediately following the armistice. In the other countries, he said, measured by the only stable currency in the world, the American dollar, the spread between American cost of production and foreign cost of production has been growing greater and greater. On the other hand, costs of production increased in this country until January, 1921.

Comparisons between the present bill and the Underwood act or the Payne-Aldrich law are of little value, in the opinion of Senator McCumber. He declares his committee gave but casual attention to either of these acts. The whole industrial, commercial and economic world has changed since those bills were enacted, he contends.

Sees Tariff Commission More Powerful

Under the bill as amended by the Finance Committee, Senator McCumber expects to see the Tariff Commission become a forum in which any complaints may be lodged as to the unfairness or the injustice of any rate. With the powers given the President, it will be possible to rectify any injustice caused by rapidly changing conditions.

On April 24 Senator Smoot addressed the Senate at length on the bill. He pointed out that tariff making is becoming more and more intricate with the progress of invention and the development of American industry. He referred to the fact that the tariff of 1890, including the free list and omitting all administrative regulations, covered only 47 pages of the size on which the bill is printed. The act of 1909 covered 71 pages, while the present bill covers 85 pages of the same size. He predicted that tariff making will continue to take more and more of the time of the legislative branch if the present method of procedure continues to be followed. If Congress is to have time for other legislative duties, he points out that it will be necessary to delegate a certain portion of the work to executive and administrative agencies. He thinks business interests will welcome any change in the tariff policy which will render less frequent and less violent the upheavals incident to tariff revision.

Believes American Valuation Impractical

The Utah Senator pointed out that under world conditions as they exist today it will be absolutely necessary to make frequent modifications of rates if the tariff is to be equitable to producer and consumer alike and does not burden unnecessarily our foreign trade. He attempted to show that American valuation would be unworkable. He said the research of the Senate committee had demonstrated that relatively few products having the same generic name as domestic articles are sufficiently similar to permit of price comparisons. The trade mark on most goods, he declared, has almost as much to do with their value as have their physical qualities. He cited specific examples to show that 28 per cent ad valorem, the American valuation equivalent of 60 per cent on foreign value, would result in American valuations varying from 164 to 297 per cent. One of the chief objections, in Senator Smoot's opinion, to adopting the American selling price of the imported article as a basis for the assessment of duty lies in the fact that an importer will reduce the selling price of any particular article which he desires to make closely competitive with a comparable domestic article. It is such articles which are used by merchants as leaders, sold at a very small marginal profit and sometimes under cost to attract trade likely to purchase other articles in his stock. American valuation permits the importer to sell his leader below the average level upon which the American valuation equivalent rate of duty necessarily would have to be based.

Senator Smoot said the Reynolds investigation, made for the Committee on Finance by the Treasury Department at a cost of $100,000, revealed conclusively the wide fluctuation in importers' margins and demonstrated that imported articles in the American market fluctuate more widely than does the value of these articles in their home markets. The Senate rates, he contends, offer greater security to the American manufacturer than equivalent rates based on American values. Nothing could be more disturbing to business, in the opinion of Senator Smoot, than a revolutionary change in the basis of valuation.

Will Oppose Dye Embargo

In his initial speech on the tariff, Senator Smoot indicated clearly that he would be active in his opposition to the dye embargo provision added to the bill by the Senate committee. He declared that the embargo may have had its justification in the period immediately following the armistice, but he believes it to be unnecessary to incorporate the plan in a permanent tariff bill. He said it is inevitable that the weaker coal-tar chemical industries will be eliminated anyway in competition with the stronger domestic concerns, and that the embargo will do little to help them and will place an unnecessary burden on the dye-consuming industries.

One of the important aims of the Senate committee's bill, Senator Smoot said, is to apply one tariff to all countries alike, and force all countries to give American products equal treatment with those accorded to other countries.

Basis of Democratic Opposition

Senator Simmons of North Carolina, the ranking Democrat on the Finance Committee, declared that the bill is based on three erroneous assumptions. One is that present importations are excessive and a menace to the business of the country. The second, he says, is the assumption that the home selling price and the export selling price of foreign merchandise are so much lower than the selling price of comparable domestic products that higher rates of duties are needed to bring about fair competitive conditions. He also branded as unsound the deductions from the Reynolds report. The report, he said, was based on selling prices in August, 1921. The committee, he asserts, has assumed that price levels have not changed since that date. He charges that the bill will cause higher prices, will add materially to the cost of living and will permit further monopolization of American industries. The rates in the Senate bill, he declared, are 40 to 50 per cent higher than the average Payne-Aldrich rates when the difference of price levels between that period and the present are taken into consideration. The current volume of imports, he declared, is not excessive and is relatively small when compared with the volume of our exports. Among the other points he made against the bill was the need for expanding foreign markets so as to absorb our surplus production from the field, the factory and the mine. If our surplus capacity is not utilized, he argued, the amount of unemployment will increase.

Crystallizing Sentiment on Muscle Shoals Presages Rejection of All Offers

Disinterested opinion on Capitol Hill is to the effect that no one of the Muscle Shoals offers will be accepted. It is believed the government will reopen work on the dam and will complete it, after which leases will be made for the disposal of the power.

A sub-committee of the Committee on Military Affairs of the House has made a formal report to the effect that no offer will be considered which does not conform to certain fundamentals. The first essential is that the property be subject to requisition at any time by the government for the production of war materials, and that Nitrate Plant No. 2 be kept in such condition as to be capable of producing nitrates at any time. Another condition, held by the sub-committee to be fundamental, is that a definite contract be entered into for the manufacture and sale to the public of a fixed quantity of mixed fertilizer. A third condition is that any deal must be made for the entire property with the exception of the steam plant at Gorgas and the transmission lines connecting it with Plant No. 2.

The Military Affairs Committee is discussing the proposition in executive session. All offers except that of Henry Ford have been tabled. The Ford offer, at this writing, is being read paragraph by paragraph. The committee expects to make its final report during the first week in May.

Senate Considers Engstrum Offer

The Senate Committee on Agriculture heard former Senator Marion Butler at great length on the Engstrum proposal for Muscle Shoals. Among other things, he said:

"Here we have two nitrate plants and two steam power plants, and the greatest hydro-electric dam in the world partly completed, which has cost the government $106,000,000. The act of Congress appropriating this money declares that it should be used to produce nitrates from the air for explosives and also for fertilizers. We produced nitrates there during the war by use of steam power; but we could not produce sufficient nitrates both for explosives and for fertilizers, therefore agriculture starved for want of nitrogen during the war.

"When the war was over, we stopped these nitrate plants, and we stopped work on the hydro-electric dam. We should correct that mistake at the earliest possible moment; with that dam finished, we could now be producing the cheapest nitrates for fertilizers in the world, but we could not even then produce as much nitrogen as is now needed for fertilizers alone until we build more nitrate plants.

"Under these serious conditions, it would be nothing less than a crime to abandon this great nitrogen project at Muscle Shoals. It will be as bad in principle and almost as bad in results to lease or sell this Muscle Shoals project to parties who will use only one-tenth of that great power to produce nitrogen while nine-tenths of it will be used for making automobiles, aluminum, etc., for private profit.

Would Utilize All Water Power for Nitrates

"The duty of Congress is plain; we should go forward and utilize this great investment and great water power to serve the public good. We should, at once, finish dam No. 2 and put both of these nitrate plants to work, day and night; we should then build dam No. 3 and put up another nitrate plant by its side. Indeed, we should go forward and develop the whole one million horsepower on that river, and use it all to make cheap nitrates for fertilizers."

Commenting on the published statement of Secretary Wallace that the War Department surplus ammonium nitrate was not being bought by fertilizer manufacturers and calling attention to the availability of Chilean saltpeter for this use, Mr. Butler said that these statements are absolutely true, but without explanation would cause misapprehension. He said that ammonium nitrate, offered for sale by the government, is not suitable for fertilizer. The imported sodium salt, on the other hand, is so expensive that the farmer is not using half the fertilizer the soil needs.

In conclusion Mr. Butler appealed to Congress either to go ahead with Muscle Shoals as a government enterprise, as provided in the national defense act, or to lease it under a contract which will produce the largest output of cheap nitrates for fertilizers as proposed by the Engstrum company.

R. R. Grant, president of the American Non-Ferrous Corporation and the Aluminum Wheel Co. of America, is conferring with War Department officials on a plan whereby the companies would take over on a 25-year contract the Muscle Shoals nitrate plant, for production of aluminum and fertilizer.

Ford Wants Gorgas Plant

Henry Ford insists that the government's equity in the steam plant at Gorgas on the Warrior River and the transmission line to Plant No. 2 be included in the property which he proposes to lease. W. B. Mayo, chief engineer for Mr. Ford, gave this message to the members of the Military Affairs Committee on April 27, when he appeared before the committee in executive session.

The committee has made up its mind quite definitely that the government should not lease the Gorgas plant and transmission line at this time. The action of Mr. Ford in demanding that these items be included in the list of property which he wishes to lease came as a surprise to the committee, a majority of which appears willing to recommend the acceptance of Mr. Ford's offer, provided it is amended in certain important particulars.

Chicago Section, A.C.S., Elects Officers—Papers on Yeast and Temperature Control

Synthetic nutrient mediums for yeast culture were discussed before the Chicago Section, American Chemical Society, on Friday evening, April 21, by Prof. Ellis I. Fulmer of the department of agricultural chemistry, Iowa State University. The effect of varying the amount of each of the following components was carefully studied: NH_4Cl, K_2HPO_4, $MgSO_4$, $CaCO_3$ and cane sugar. Points of optimum concentration were found in some cases, notably ammonium chloride and calcium carbonate, which explain conflicting results reported previously. As a result of this work, yeast has been grown continuously for 2 years by subculturing in a medium containing only K_2HPO_4, NH_4Cl and sugar.

At the group meeting on synthesis, R. C. Shuey of the Redmanol Chemical Products Co. described the methods used for controlling the temperature during the various steps in the manufacture of synthetic resins. The reactions are exothermic and very careful regulation is essential in order to keep a batch from getting beyond control. A system comprising a thermocouple element operating a small compressed air valve which in turn controls the movement of the main valve was found very satisfactory in regulating steam-heated stills where the pressure in the steam line was kept practically constant.

Officers were elected as follows: Chairman, C. S. Miner; first vice-chairman, P. N. Leech; second vice-chairman, E. S. Weirick; secretary, S. L. Redman; treasurer, O. N. Berndt; editor of the *Chemical Bulletin*, E. H. Volwiler; trustee, W. Lee Lewis; councilors, D. K. French, H. N. McCoy, L. V. Redman, W. R. Smith, Ethel M. Terry, L. M. Tolman, Paul Van Cleef, G. L. Wendt, F. C. Whitmore; Willard Gibbs jurors, Lauder W. Jones, W. Lee Lewis, H. N. McCoy, J. H. Mathews.

Immigration Bars Hinder Erection of German Briquetting Machinery

Half a million dollars worth of German briquet-making machinery, contracted for to be used in connection with the lignite deposits in Victoria, Australia, may have to be refused, since under the Australian immigration act of 1920, Germans are prohibited for a time from entering the country and the two experts who were to have put up the machinery are being kept out. The question is being actively discussed, and references have been made as to the possibility of obtaining similar machinery in the United States to take the place of the German machinery, or else to employ Americans to erect the German machinery.

Information Desired on Standard Analytical Methods

American Engineering Standards Committee, 29 West 39th St., New York City, would be glad to hear from chemists who are using the A.S.T.M. Standard Methods for Chemical Analysis of Tin, Antimony and Copper, and their methods for laboratory sampling and analysis of coke, as to the extent the specifications are used, and any comment on their usefulness. These are proposed as "Tentative American Standards."

Dye Hearings About to Close—Developments of Past Week

Hearings before the sub-committee conducting the dye investigation were virtually brought to a close last week. This was the outstanding development of the week, although a touch of light drama was injected by the National Association of Hosiery and Underwear Manufacturers when their counsel was interrupted in the midst of his testimony and told that his clients had suddenly decided not to play any more. As far as Senator King's monopoly charges are concerned, it seems pretty generally accepted that the industry has shown a clean bill of health and the only mention made of monopoly during the testimony were the occasional references which seemed necessary to entitle the speakers to the floor before such a committee.

The sub-committee plans to hear Paul Pickhardt of Kuttroff, Pickhardt & Co. and representatives of the Chemical Warfare Service this week. Senator Shortridge announced that every opportunity would be given to anyone believing he has additional evidence of importance to present it. He also announced that the sub-committee will discuss the reparation dyes situation with Secretary Hughes some time this week.

Socks and Shirts—A Comedy in Three Acts

The first appearance of representatives of the National Association of Hosiery and Underwear Manufacturers was on March 11, when George Demming, a lawyer, of Philadelphia, handed Senator Shortridge a letter violently attacking the conduct of the dye investigation, after which he promptly disappeared. The letter purported to express the sentiment of the association, and was quite caustic in its criticism of the sub-committee's methods. Shortly afterward John N. McCullaugh, consulting industrial manager for the association, denied authorship of the letter and asked that it be stricken from the record.

The second act opened on April 20, with Mr. McCullaugh testifying as to Mr. Demming's unquestioned right to speak for the association in testimony before the sub-committee. He stated that Mr. Demming was appointed special counsel for the association and was authorized to appear for it by authority of the board of directors.

The third act is laid at the next meeting of the sub-committee 5 days later. Mr. Demming's testimony was suddenly and dramatically interrupted by Mr. McCullaugh, accompanied by Joseph Rambo of Philadelphia, one of the board of governors of the association, who declared that by authority of a majority of the board of directors of the association he wished to withdraw Mr. Demming as its representative and to withdraw his evidence as far as the association was concerned.

Both Mr. Demming and Senator Shortridge expressed surprise at this action. Mr. McCullaugh explained the changed attitude by saying that a majority of the board of directors had decided that "we have our own hands full with our own business" and did not wish to interfere in the hearing.

Hosiery Company Supports Embargo

Senator Shortridge read a telegram from John Fitzgibbon, manager of the Phoenix Knitting Works, Milwaukee, Wis. The text of the telegram follows:

> We have noticed George Demming's opposition before your committee to selective embargo protection for American dye manufacturers. As one of the largest hosiery manufacturers of the country and also a member of the National Association of Hosiery and Underwear Manufacturers, we entirely indorse a selective embargo as applied to dyestuffs. We strongly urge you and your associates to give adequate protection to American dyestuffs manufacturers to enable this industry to continue successfully. We buy substantial quantities of American dyestuffs for our plants and find American manufacturers are manufacturing dyes of equal quality with the German products at reasonable and continually decreasing prices and that cost of American dyes is no hardship to us.

Isermann Testifies Again

Representing the small dye manufacturer, Samuel Isermann, with statistics at his fingertips and keenly aware of the facts, added to his previous testimony as to the value of the embargo and the competition among domestic producers. The selective embargo has smashed the German grip on dyes and other coal-tar products, he said. The results have been of incalculable value to American consumers, for when it swept away the monopolistic control here of German manufacturers the exorbitant prices charged for many products were likewise broken. Dr. Isermann cited examples in perfumes and drugs, showing how American manufacturers had brought down exorbitant German prices.

The witness then attacked the testimony of H. A. Metz, in which the latter stated that his manufacturing interests are greater than his importing interests. Dr. Isermann also made a detailed attack on the testimony of E. R. Pickrell, of Mr. Metz's staff, and criticized the testimony of Ward Thoron, of the Merrimack Manufacturing Co., who based much of his testimony on the term "drugs," which, as Dr. Isermann pointed out, included many things in addition to dyestuffs.

The Small Producer and American Monopoly

Dr. Isermann emphasized the great strides made by American dye manufacturers since the war and pointed out the importance of the small manufacturer in developing the processes. He recounted briefly the reasons set forth by previous witnesses showing why more than a tariff is needed to protect the American industry, and then took up in more detail the problem of substitution.

Less than a thousand different dyes were imported into the United States prior to the war, he said. But for each one of these dyes imported there were satisfactory substitutes which would produce substantially the same results when used in substantially the same manner, and the German chemical industry knew how to make them. If a tariff was written for the protection of one American dye the German producers could simply turn to a substitute product not specified in the tariff law, he said.

There is quite a danger that large concerns by cutting prices will force the smaller companies out of business, and it has been suggested that in course of time there might be a tendency to form a monopoly. There is a possibility that this could take place, but competition today is keen.

Metal Failures Discussed by Steel Men

"The Influence of Quality From the Standpoint of Workmanship and Material" was the title of the address by Frank P. Gilligan, president of the American Society for Steel Treating, before the Washington chapter of that organization on Friday, April 21. Mr. Gilligan, who is the vice-president of the Henry Souther Engineering Co., of Hartford, Conn., discussed his general subject broadly, but gave particular attention to the question of metal failures, which he and his engineering organization have investigated thoroughly. The importance of quality in relationship to metal performance was emphasized.

King Would Investigate Alien Property Activities

Senator King of Utah has introduced a resolution for an investigation by a committee of five Senators of various activities of the Alien Property Custodian, including the sale of patents, trade marks and trade names to the Chemical Foundation, or others.

American Institute of Chemical Engineers to Hold Conference on Chemical Engineering Education

The American Institute of Chemical Engineers is arranging for a conference on the report of its committee on chemical engineering education presented at the Baltimore meeting. Invitations have been sent to the presidents of eighty-three universities and technical schools which offer courses in chemical engineering to attend or send representatives to the conference for discussion of the report. A printed copy of the report was sent with the invitations. The conference will be held on May 16 at the Brooklyn Polytechnic Institute, sessions being held at 10 a.m. and 2:30 p.m. and also at 8 p.m. if necessary.

A preliminary report of the findings of this committee was presented at the Detroit meeting of the Institute and was published in CHEMICAL & METALLURGICAL ENGINEERING, vol. 24, No. 24, pp. 1047-53, June 15, 1921.

Power Test Codes Committee Completes Three Codes to Be Discussed at A.S.M.E. Meeting

On Tuesday morning, May 9, of the spring meeting of the American Society of Mechanical Engineers in Atlanta, Ga., a public hearing is set for the discussion of the three additional power test codes which have reached this stage in their development during the past year. Last May at Chicago this committee, of which Fred R. Low, editor of *Power*, is chairman, presented codes on general instructions, steam engines and evaporation apparatus. It now presents codes on definitions and values, displacement compressors and blowers, and hydraulic power plants, all three of which have appeared in *Mechanical Engineering*.

Though these codes have passed through six successive revisions in reaching their present form, the committee will welcome a full and frank discussion by the members of the society and others interested. Members not planning to attend the spring meeting and others are invited to prepare written discussions.

Reprints of all three codes revised to date have been prepared by the committee and may be obtained by addressing C. B. LePage, secretary to the committee, at the society's headquarters.

In 1918 the power test codes committee of the A.S.M.E. was reorganized to revise and enlarge the power test codes of the society, published in 1915. The committee is a large one, consisting of a main committee of twenty-five under the chairmanship of Fred R. Low, and nineteen individual committees of specialists who are drafting codes for the different classes of apparatus comprised in power-plant equipment.

Symposium on Glycerine and the Fatty Acids

An extremely practical treatment from the industrial standpoint featured the symposium on glycerine and the fatty acids held at a joint meeting of the Society of Chemical Industry, American Chemical Society, American Electrochemical Society and the Société de Chemie Industrielle at the Chemists' Club, New York, April 21.

J. W. Bodman, of William Garrigue & Co., gave a very interesting talk on the distillation of glycerine from the standpoint of a chemical engineer. The talk was profusely illustrated with slides showing details of the apparatus and process. The distillation of glycerine is essentially an application of the principle of a double effect vacuum evaporator. In the manufacture of dynamite glycerine, the apparatus used consists essentially of an evaporator, two condensers known as the superheater and cooler, and a concentrator. The steam used in the concentrator is obtained from the evaporator, and the sensible heat in the vapors as well as the latent heat of evaporation of the glycerine is used in the heat interchangers.

It would be possible to condense all the glycerine in the first condenser, but in practice a certain amount is permitted to go through to the second condenser, as otherwise some of the lower fatty acids would condense out with the glycerine. The construction details of the tubular copper condensers and of the ingenious catch-all, which throws out some of the salt between the still and superheater, were shown.

In the manufacture of pure glycerine, the first distillate is diluted, treated with lime, filtered and redistilled. The yield of the operation depends upon the disposal of the "foots." In good operation about 94 per cent of dynamite glycerine is obtained, with 4 per cent in the "foots" and 1.9 per cent in the "sweet water." Mr. Bodman pointed out the saving accomplished by the utilization of the latent heat of vaporization of glycerine.

Passing to the subject of the distillation of fatty acids, Mr. Bodman described the commercial process and gave some interesting figures on the fatty acid and glycerine yields from stocks from different sources.

R. C. Farra, of the Standard Textile Products Co., Passaic, N. J., described the modern method of manufacture of oilcloth, describing the qualities desired in the fabric, the calendering process which precedes coating and the preparation and coating of the "daub." The oil is boiled for 2 hours at about 600 deg. F., some oxide of lead, iron or manganese having been added to aid the oxidation. These so-called driers also prevent the "separation" of the oil. The oil is cooked to a standard viscosity and mixed with china clay. Alkali, usually ammonia, is added, giving a water in oil emulsion. A solution of casein or other sizing is added, giving an oil in water emulsion, which can be thinned to proper consistency with water. The fabric is coated and surface dried for 5 minutes, when the second coat may be applied. Final drying is carried out in a festoon drier for about 8 hours at 130 deg. F. The pigment used for white oilcloth is zinc oxide and for black oilcloth is carbon black. The glazing operation was described and several promising lines of research were suggested.

A. C. Langmuir discussed the need for a standard method of evaluating glycerine.

American Ceramic Society Plans Summer Trip to England and Europe

In response to an invitation extended last year by the British Society of Glass Technology, the American Ceramic Society is making arrangements for a party to sail from New York on the Cunard liner Aquitania, Aug. 22.

With regard to the reception of members interested in things other than glass, Dr. Turner writes that the refractories group surely will be welcome. While negotiations are still pending for the other groups, there have been no definitely unfavorable reports.

Dr. Turner has in charge the arranging of the tour of England, which will require about 3 weeks after arrival in England. Special trips will be arranged for the several groups representing the divisions of the society. Those wishing to visit the Continent will be expected to make their own arrangements, since no organized visit will be made.

All members interested are urged to communicate at once with Dr. E. Ward Tillotson, Mellon Institute, Pittsburgh, Pa.

American Leather Chemists Association to Hold Summer Meeting in Canada

Bigwin Inn, delightfully situated in the Lake of Bays district, Ontario, Canada, has been chosen for the nineteenth annual meeting of the American Leather Chemists Association, June 21 to 23. In addition to the usual committee reports, special addresses of interest to the tanner as well as the chemist are being arranged. Prof. F. E. Lloyd of the department of botany, McGill University, will speak on "The Mode of Occurrence of Tannin in the Living Cell." Several papers will be contributed from the Leather Research Laboratory of the Tanners' Council in the University of Cincinnati. Titles of two of the papers have been announced by Prof. McLaughlin—"Bacteriology of the Fresh Hide" and "The Science of Curing." Further details will be given as they assume definite form.

The association is particularly desirous of having the practical men of the industry well represented at the meeting, it being felt that there will be much of interest to them on the program.

Domestic Potash Producers Encouraged by Tariff Prospects—Operations Resumed

Domestic producers of potash are much pleased with the action of the Finance Committee of the Senate in approving the potash paragraph put into the tariff bill by the House. Commenting on this action, Frederick W. Brown, the executive secretary of the United States Potash Producers' Association, says:

"No industry ever presented a fairer proposal in seeking protection. A study of the potash situation is all that is necessary to reveal the justice of the American producers' request for a diminishing scale of duties. The industry should be protected, not only that we may be insured an increasing production of domestic potash but in the interest of the farmer himself.

"With the indorsement of the committee, only one step remains to be taken—the passage of the item by the Senate —to free America from the foreign potash monopoly."

Operations Resumed at Searles Lake

The American Trona Corporation resumed operations at Searles Lake April 10, with expectations of reaching a record production of potash and borax in the near future. With the exception of an installation of new condensers, no change has been made in the operations or equipment since the shut-down. The company plans to apply the results of recent research to the production of several new byproducts as soon as practicable.

"Informashow" Planned in Connection With Rochester Meeting of Purchasing Agents

An "Informashow," an industrial exhibition with a new idea behind it, is scheduled in Rochester, May 15 to 20, in connection with the convention of the National Purchasing Agents' Association which is to be held there at that time.

The consideration which chiefly influences the purchasing agent is value, which comprises service, quality and favorable price. These considerations sum up the benefits that the corporation will derive as a result of the purchase. Consequently, any exposition that shows the value of equipment should be of value to purchasing agents. The "Informashow" is designed as a medium for demonstrating the value of various industrial equipment, and to furnish an opportunity for the seller to inform others of the value of his product and for the purchaser to learn. With this principle in mind, every effort has been made to include exhibits which demonstrate the value and uses rather than the products themselves. About 100 exhibitors have reserved space. It is expected that about 1,200 purchasing agents will be present.

Minerals Separation Suits Closed by Settlement

On April 28 the negotiations which have been in progress during the last 4 or 5 weeks between the Minerals Separation and the Jackling interests and also the Miami Copper Co. terminated in a settlement satisfactory to all parties. This settlement will, therefore, terminate the hearings before the masters in the Butte & Superior case and the Miami Copper Co. case, as well as the cases pending in courts against all the mines of the Jackling interests.

Personal

W. H. Alger of Orange, Va., has been elected president of the Amelia Mica Mining & Developing Co., Chula (Amelia County), Va. W. W. Alger has been elected vice-president and R. B. Roberts secretary and treasurer.

Dr. Hugh P. Baker, executive secretary of the American Paper and Pulp Association, will spend 8 weeks in Europe this summer studying conditions in the paper industry in Norway, Sweden, Finland, Germany, Austria, Poland and Czechoslovakia. The Department of Commerce is particularly interested in the effect on the paper industry here and abroad of the establishment of the new European republics and the revision of boundaries. Dr. Baker will bear a special commission to study this phase for the department.

J. W. Bostwick has been appointed general manager of the Kansas & Gulf Oil Corporation, with headquarters at Tulsa, Okla.

H. C. George, of the petroleum division of the Bureau of Mines, is en route to Alaska.

Prof. W. D. Harkins of the University of Chicago addressed the Franklin Institute in Philadelphia on April 19, taking for his subject "The Structure and Building of Atomic Nuclei."

F. M. Harrison, president of the U. S. Industrial Alcohol Co., New York, has resigned. He will be succeeded by H. S. Rubens, chairman of the board of directors, who will continue also in the latter capacity.

The partnership of Huntoon & VanArsdale has been discontinued. L. D. Huntoon will continue practice as consulting mining engineer at 115 Broadway, New York City, and G. D. VanArsdale will continue practice as consulting chemist and metallurgist at 1011 South Figueroa St., Los Angeles, Cal.

Dr. Irving Langmuir of the General Electric Co. spoke before the Delaware Section of the American Chemical Society in Wilmington on April 19 on "Molecular Structure and Its Relation to Chemical Valence."

Charles A. May, president of the Maddock Pottery Co., Trenton, N. J., was the guest of honor at the tenth anniversary banquet celebration of the local Federal Club, April 18.

Prof. Alan C. W. Menzies of Princeton University addressed the Philadelphia Section of the American Chemical Society on April 20, on "Modern Study of the Atom."

C. Wilbur Miller, president of the Davison Chemical Corporation, Baltimore, Md., plans to sail for Europe May 16, for business and pleasure, and will be absent for a number of weeks.

H. O'Connell of Plattsburg, N. Y., has been engaged by the Dexter Sulphite Pulp & Paper Co. of Dexter, N. Y., as chemist in charge of the chemical laboratory and experimental station.

Edgar S. Ross, formerly chief chemist for the Charlotte Chemical Laboratories and Columbite Reduction Co. of Charlotte, N. C., and for the past several years engaged in private research concerning the metals tantalum and columbium, is now chemist and assistant manager for McKechnie Bros., Inc., metal smelter and refiner of Philadelphia, Pa.

Kenneth D. Tucker, connected with Magnus, Mabee & Reynard, New York, manufacturers of essential oils, and previously associated with the essential oil department of the National Aniline & Chemical Co., resigned May 1, to engage in business with his father.

Obituary

Sir John Benn, known in England as the "father" of the London County Council, and chairman of the board of Benn Bros., Ltd., the largest publisher of technical and trade papers in Great Britian, died in London, April 10. He entered the field of business journalism in 1880, when he established the *Cabinet Maker*, devoted to the furniture trade. The venture succeeded and in time the business expanded until at his death the firm was publishing thirteen business journals, including the *Chemical Age*, the *Electrician* and the *Gas World*.

George C. Ripley, superintendent of the Electrolytic Zinc Refinery of the Anaconda Copper Mining Co. at Great Falls, Mont., died on April 17, 1922, of pneumonia. He graduated from the Colorado School of Mines in 1906, then spent about 10 years in China and the Philippines. Returning to the United States, he joined the operating staff at Great Falls shortly after the electrolytic zinc department started operations.

Market Conditions

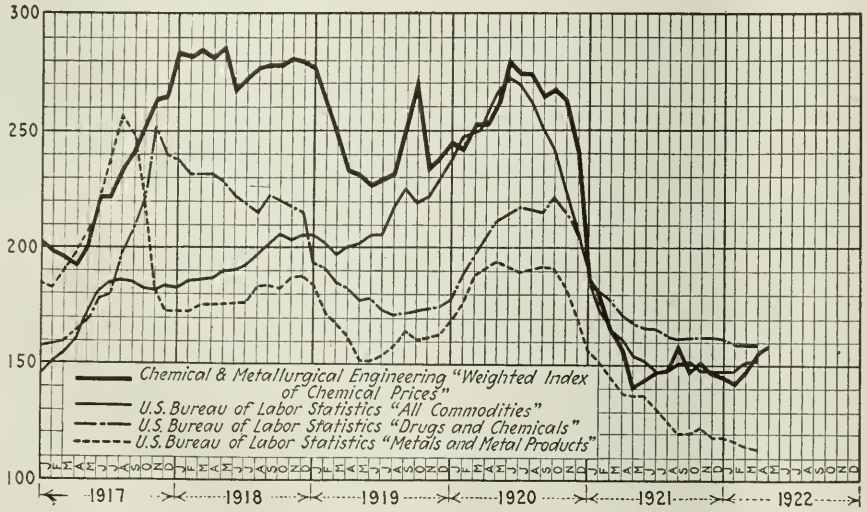
IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

April's Progress Toward Better Business

Continued progress was made during April in the return to that mythical state of business which we sometimes call "normalcy." That term, to be sure, is capable of many interpretations and to the individual manufacturer it is likely to mean the particular time at which his own plant was running at its maximum capacity. Normalcy so defined may never be reached again, but certainly there is much in the fundamental economic situation to indicate that better business is definitely ahead.

Many powerful factors are making for an industrial betterment that cannot be accounted for strictly by seasonal influences. Of these factors, four are outstanding at the present time: (1) A larger volume of manufacture is evident in many of the basic industries. (2) Increases in wholesale prices are gradually predominating over the decreases. (3) There has been a noticeable easing up of money rates which has directly or indirectly resulted in (4) sustained strength and unusual activity in the stock and security markets. The most prominent gains in production are probably in the iron and steel industries. In the face of firm and even advancing prices, steel production has increased until present operations are in the neighborhood of 75 per cent of capacity as compared with 40 per cent at the beginning of the year. This rate approximates that for the year 1913. The monthly output of steel ingots in March (2,370,751 tons) was better than at any time since November, 1920. Pig-iron production during April was said to be larger than for any month since January, 1921.



THE UPWARD TREND IN CHEMICAL PRICES SINCE JANUARY, 1922

In other basic industries, especially paper, petroleum products and certain of the heavy chemicals, there has been a moderate increase in manufacturing output. Probably some little gain in freight movement of general commodities has occurred, although car loadings, the usual index of this movement, have fallen off somewhat during April. This has been due largely to the coal strike and the feverish activity which preceded it. For example, car loadings during the week ended April 8 were 714,268 cars, as compared with 827,011 during the previous week, a reduction of 112,743 cars. Coal loadings for the same week in April totaled 69,456, a decrease as compared with the week before of 115,496 cars.

The activity in the stock market which has been noted in our earlier reports continued without interruption during April. Toward the end of the month there were occasional tendencies toward reaction and a rather general feeling that the peak has been reached in the present upward movement. The *Annalist's* average of twenty-five industrials, which stood at 73.0 on Aug. 1, 1921, had mounted to 92.9 by April 1 and ended the month at 96.6. A similar gain had been shown in CHEM. & MET.'S average of the stocks of twenty representative companies in the chemical and allied industries, which rose from 46.1 on Aug. 1, 1921 to 63.8 on May 1, 1922. A comparison between the low figures of 1921 and the recent high for certain chemical, metallurgical and related industrials gives a definite idea of the extent of this appreciation. The approximate gains in actual dollars based on the outstanding stock issues have been calculated by W. J. Wollman & Co. and are shown in Table I.

One of the factors of potential importance is the coal strike, although its effect has not, and perhaps may not, be felt by industry in general. The recent rise in iron and steel prices has been attributed in part to the trouble in the coal fields, but certainly there were other factors of more serious import. About the only element of surprise in the situation has been the larger number of non-union

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

This week	158.41
Last week	158.27
May, 1917	222
May, 1920	279
April, 1918 (high)	286
April, 1921 (low)	140

This index number is based on the wholesale prices in the New York market for acetic acid, citric acid, hydrochloric acid, nitric acid, sulphuric acid, ethyl alcohol, methanol, anhydrous ammonia, ammonium sulphate, barium chloride, bleaching powder, borax, caustic potash, caustic soda, copper sulphate, formaldehyde, glycerine, potassium carbonate, saltcake, soda ash, crude sulphur, benzene, aniline oil, cottonseed oil and linseed oil.

TABLE I—RECENT APPRECIATION IN THE STOCKS OF CERTAIN CHEMICAL, METALLURGICAL AND ALLIED COMPANIES

Stock	Low of 1921	Recent High	Approximate Gain in Dollars
Allied Chemical & Dye Corp	34	68	$73,763,578
Anaconda Copper Mining Co	31¾	54½	68,250,000
American Smelting & Refining Co	29⅝	59½	18,223,152
American Sugar Refinery Co	47⅛	74½	12,037,500
Corn Products Refining Co	59	108	24,394,160
Davison Chemical Co	23	63	8,000,000
General Asphalt Co	39½	65½	5,118,958
Mexican Petroleum Co	84½	135½	21,903,649
U. S. Steel Corp	70¼	99¼	147,407,725

miners who have joined the movement. As yet there is no indication of the settlement of the strike, and even when it does come it can scarcely be regarded as a permanent answer to the problem of the bituminous coal industry. The only satisfactory solution will depend upon the elimination of the intermittent operation caused by overcapacity and overproduction.

The foreign exchange market has remained comparatively stable throughout the month, presumably pending the results of the Genoa conference. All of the exchanges have, however, shown slight recoveries from the low levels reached toward the end of March. Sterling rose from $4.37 on April 1 to $4.41⅜ on April 15, and has since maintained this level. German marks, which on March 27 had fallen to $0.0028⅝, the lowest on record, recovered to $0.0035 toward the end of April. French francs rose from 9.09c. on April 1 to 9.26½c. on April 20.

The continued rise in general wholesale prices during March as indicated by the index numbers of the Bureau of Labor Statistics, were reviewed in last week's issue. These slight gains were probably maintained for most commodities during April, although comparatively few striking advances were recorded. Chemical prices, however, may be regarded as an exception in that higher prices were maintained throughout practically the entire list. CHEM. & MET.'s weighted index of chemical prices averaged 158.04 for the month of April, as compared with 156.19 for March. These are the highest quotations since August, 1921, and show a gain during the last 3 months of approximately 16 points.

Not all the factors in the business situation may be regarded as favorable, and some setbacks are bound to occur, but it may be said with no undue optimism that the industries served by CHEM. & MET. are gradually emerging from the period of depression.

Margarine Production in 1921

The annual report of the Commissioner of Internal Revenue for the fiscal year ended June 30, 1921, gives the following figures for the production of oleomargarine as well as the materials entering into its manufacture. The difference of about 60,000,000 between the total weight of vegetable oils and other materials consumed and the output of finished margarine is due almost entirely to the water content of the milk.

	Lb.
Oleomargarine, produced	281,081,514
Materials consumed:	
Cocoanut oil	103,111,916
Milk	79,715,584
Oleo oil	49,675,749
Neutral oil	29,267,960
Salt	25,365,499
Cottonseed oil	18,532,860
Peanut oil	16,332,498
Vegetable oil	6,559,034
Oleo stearine	4,857,972
Oleo stock	2,065,231
Butter	1,498,625
Corn oil	925,999
Soy bean oil	461,129
Edible tallow	233,227
Mustard seed oil	109,748
Coloring	25,915
Miscellaneous	3,216,742
Total materials	341,955,688

International Paper Shows Loss

Another company to make an unfavorable report for operations in 1921 is the International Paper Co. The net loss for the year before payment of preferred dividends was $7,442,890. Of this amount $6,276,607 was for depreciation of inventory, although at the ordinary rate of depreciation this would amount to only about $2,379,967. The operating profit for the year was $1,542,642 notwithstanding the fact that during May and June the company's mills were shut down on account of a strike.

President Dodge in the report significantly stated that inventory might have to be adjusted either way at the end of 1922. General opinion is that prices of pulpwood have reached bottom and can be expected to move upward later this year when the large buying interests come into the market.

Government Nitrate Sales

Prices obtained for the nitrate of soda recently sold by the government are as follows:

At the Old Hickory Ordnance Reserve Depot, $42.50 per ton; at Middletown Ordnance Reserve Depot, $47; at Nitro, W. Va., $41 and at Morgan General Ordnance Depot, $50 per ton.

The successful bidders were Baugh Chemical Co., Baltimore; Baugh & Sons Co., Baltimore; M. D. Biddeson, National Aniline & Chemical Co., New York; Butterworth-Judson Co., New York; Caraleigh Bros. & Fertilizer Co., Raleigh, N. C.; Egyptian Powder Co., East Alton, Ill.; Equitable Powder Co., East Alton, Ill.; Farmers Fertilizer Works, Elizabethtown, Pa.; Farmers Guano Co., Norfolk, Va.; J. R. Gay, Gay, Ga.; W. R. Grace & Co., New York; General Chemical Co., New York; Granton Chemical Co., New York; Graselli Chemical Co., Cleveland, Ohio; King Powder Co., Cincinnati, Ohio; Lancaster Chemical Co., Lancaster, Pa.; Mahoney & Hoban Chemical Co., New York; John K. McIver, Savannah, Ga.; Read Phosphate Co., Savannah, Ga.; A. F. Pringle, Charleston, S. C.; Senior Powder Co., Cincinnati, Ohio; Southern Agricultural Chemical Corporation, 61 Broadway, New York; Stauffer Chemical Co., Chauncey, N. Y.; Tennessee Copper Co., 61 Broadway, New York; Trojan Powder Co., Allentown, Pa.; Wessel Duval Co., New York; York Chemical Co., York, Pa.

The New York Market

NEW YORK, May 1, 1922.

In general the chemical market during April was not up to expectations of many observers. Although the early advances were practically all maintained throughout the month, activity was confined to comparatively few commodities, and the remainder of the list was almost entirely neglected. However, leading producers now report a very favorable outlook and in many cases production has been increased considerably in order to take care of recent new business.

DEVELOPMENTS OF THE WEEK

The market during the past week has remained quite steady throughout the entire list. Although buying cannot be called brisk, the general feeling in the trade is very optimistic. The basic reason for this condition lies in the present strong position of caustic soda, which is the recognized barometer of trading in the chemical market. The export demand for this commodity has been very active during the past month and with domestic producers quoting lower prices than foreign competitors the outlook is promising for a continuance of active trading. May shipments are practically sold up among the more important factors and in some instances the output is booked as far ahead as the latter part of June.

One of the leading features in the week's trading was the notable rise in the prices of prussiates. Consumers resumed their former buying operations and a marked difference was noted in the final quotations. Still another feature was the continued activity in the market for barium products. During the week barium chloride touched a new high level. Glaubers salt and chlorate of soda have also attracted increased attention from the consuming industries. Bleaching powder developed a steadier tone. Copper sulphate merited added interest and producers reported a sold-up condition.

GENERAL CHEMICALS

Barium Chloride—Spot material is very scarce and it is doubtful if better than $105 per ton could be done on available round lots. Some dealers quoted up to $110 per ton. The acute shortage is the principal reason for the present strength.

Carbonate of Potash — Spot quotations have shown a firmer tendency and the demand was rather active. Calcined 80-85 per cent was quoted at 5c. per lb. Some odd lots were still available at 4¾c. per lb.

Copper Sulphate—The market for this product is much firmer and the demand seems to be exceeding the supply.

Producers quote prime large crystals 99 per cent at 5½c. per lb. and small crystals at $5.40 per 100 lb. The general tone is good and the consensus is for higher prices in the very near future.

Glaubers Salt — The demand has shown a considerable increase during the past week and large tonnages were moved at higher prices. Several carlots in barrels were sold at $1.05 per 100 lb., with lesser quantities quoted up to $1.25. Bag material did not find a ready market, and quotations continued to sag at 85c. per 100 lb. Domestic prices for bags were held at $1.25 per 100 lb. and $1.40 for barrels.

Prussiate of Soda—The market for this material recorded a sharp advance owing to the renewed interest shown by large consumers. Several odd lots were available at the close of trading at 17½c. per lb., with the majority of holders not inclined to offer at any figure. Shipments were quoted at 17c. per lb.

Soda Ash—The market continued steady throughout the entire week with spot goods quoted firm at $1.80 per 100 lb. for carloads in single bags and up to 2c. per lb. for smaller lots. Barrels were quoted at 2@2¼c. per lb. Leading factors offered contracts at $1.20 per 100 lb. in single bags and $1.40 in barrels, basis 48 per cent, f.o.b. works.

Vegetable Oils

Linseed Oil — The market for this material was very steady early last week, but eased up considerably at the close. Crushers were offering shipment oil at 86c. per gal. Consuming interest has fallen off considerably during the last few days, owing to the present high price. English material ex-dock sold as low as 81c. per gal., duty paid. Shipment oil was somewhat higher at 82c. Dutch oil on spot sold at 81½c.

Chinawood Oil — The market on spot was rather steady under an improved inquiry. Spot oil sold in small lots at 13½c. per lb. May arrival at New York was offered at 12½c., with June-July at 12½c. per lb.

Coconut Oil — This material showed a tendency to ease off and some dealers were inclined to shade prices. Prompt shipment from the coast in tanks sold at 7¼c. per lb. Ceylon type oil in New York was quoted at 7⅞c. per lb., sellers' tanks.

Corn Oil — Offerings of crude corn oil were somewhat scarce and prices ranged from 9¾@10c. per lb. Spot crude in less than carloads sold at 11½c. per lb.

The St. Louis Market

St. Louis, April 25, 1922.

The movement of heavy industrial chemicals since our last report could not be termed vigorous in every respect, but the demand has increased and is showing up very favorably in the larger volume of sales. The lack of confidence prevailing several weeks ago has been entirely subdued by a feeling of optimism which is a positive indication that the improvement will be a permanent one. The demand for chemicals emanating from industrial sources has added greatly to the present condition of the market. Furthermore, with the approach of the spring and summer seasons there are many commodities that will move in a larger way and will add substantially to the volume of business transacted. This should be an opportune time to cover for several months' requirements, as prices in general have begun to advance and probably will continue in this direction with the increased activities.

Alkalis

The singular innovation of a chemical dealer advertising his wares in the daily paper was introduced to the St. Louis market last week, and through it we have the following prices on alkalis: *Caustic soda*, 76 per cent, solid, in 5-drum lots, $3.93 per 100 lb.; flake, 76 per cent, $4.41½ per 100 lb.; *soda ash*, 58 per cent, light, in bags, $2.21½ per 100 lb., in barrels, $2.45 per 100 lb. So far as we are able to determine this price is being met by all dealers. *Bicarbonate* can be obtained at $2.25 per 100 lb. in 5-bbl. lots, with the demand light. *Sal soda* has declined 10c. per 100 lb. during the interval since our last report.

General and Special Chemicals

Reports coming from the heavy *mineral acid* manufacturers are very favorable and the tone of the market has greatly improved during the current month. Manufacturers have today advanced their price on *acid carbolic crystals*, also the liquid medicinal grade, 1c. per lb., with the demand very favorable. *Citric acid* is in good demand, with a scarcity of stock, and an advance in price would not prove at all surprising. *Ammonia water*, 26 deg., has been in better demand for the past several weeks with a firm market. *Carbon bisulphide* is firm and the demand very encouraging. Last week factors in *chloroform* reduced their prices 5c. per lb. on both the U.S.P. and anesthesia grades. Stocks of *copperas* continue to move into consumptive channels as fast as accumulated and the demand is still far in excess of the production. A reduction of 1c. per lb. in the price of c.p. *glycerine* did not stimulate the market extensively, and it is still a slowly moving item; a further decline would not come as a surprise. *Sulphur* is still holding with no change in price and apparently a good demand.

Vegetable Oils and Naval Stores

Castor oil is holding firm, with an increasing demand for spot goods. *Turpentine* can be bought today at 85c. in drums, which happens to be the same as in our last report; the prices have been up and down during the interval.

Paint Materials

Ochers have advanced slightly, while *oxides* suffered a decline. *Zinc oxide*, lead free, is offered at 7⅞c. in barrels, 7½c. in bags in carloads; warehouse price at 8c. and 8½c. *Zinc oxide* containing 5 per cent lead at ¼c. less, and 8 to 10 per cent lead at ½c. less on above lists. *Barytes* is quoted at $23 in carloads and $24.50 in less than carlots in barrels. Prices per ton for *whiting* follow:

	Barrels	Paper Bags	Cotton Bags
Whiting—Commercial	$15.50	$13.50	$15.00
Extra gilders	16.50	14.50	16.00
Putty whiting	10.50	10.00	11.00
Vera blanc	17.00	15.00	16.50

The Iron and Steel Market

Pittsburgh, April 28, 1922.

The volume of business in finished steel products, as a whole, has been decreasing somewhat and is now at a materially lower level than the average of March. The decrease in general buying is still greater, for there has been some activity in railroad material, particularly in connection with freight cars.

Buyers and sellers alike contribute to the decreased market activity. There is less inquiry on the part of many buyers, including both jobbers and manufacturing consumers, obviously because they anticipated present requirements by buying in February and March, having in mind the coal strike of April 1. Among steel producers there is decidedly less disposition to sell. In most quarters this disinclination is attributed entirely to the coal strike, with its tendency to prevent increases in steel production, but as a matter of fact part of the disinclination is only indirectly connected with the coal strike, the point being that in some cases the steel mill believes that the inquiry is due to the coal strike and thus has a little speculative flavor. There are cases in which a consumer refused to buy recently but now urges a mill to accept his order, when there is no evidence that his actual requirements have changed, the change being in his mental attitude, and the sales manager reflects that such a buyer may change his mind once more.

Strike Situation Largely Met

The steel producers affected by the Connellsville region strikes have largely met the situation. Except in the case of a few merchant furnaces, production is being maintained at nearly if not quite the rate obtaining at the end of March, and in all cases at much above the rates of earlier in the year. Since April 1, when it developed that non-

union strikes in the Connellsville and Lower Connellsville region would be much more extensive than had been expected, there has been aggressive buying of coal by several large interests and in various districts. There is some Connellsville coal available for purchase, production being perhaps maintained by paying "bonuses" to the miners, while there is much coal to be obtained in West Virginia and Kentucky. The Elkhorn, Ky., coal runs under 4 per cent ash and under 0.60 per cent sulphur, lower limits than the Connellsville region ever showed, and there is to be quite a movement of it to the Clairton byproduct plant of the Carnegie Steel Co., which normally has used only Connellsville coal and was moderately well stocked with it on April 1. The Carnegie company is blowing thirty-one or thirty-two blast furnaces, against thirty-four on April 1, but might be operating forty by this time had no strikes occurred. The Steel Corporation has increased its steel production in the Chicago district, which would scarcely be affected by the coal strike before July.

Steel ingot production cannot be estimated closely, but is probably running at between 36,000 000 and 38,000,000 tons a year. The rate was about 35,000,000 tons April 1, 30,000,000 tons March 1 and 20,000,000 tons in December. Thus if a material decrease in steel production should be forced, the rate would not be set far back in point of time.

As a matter of fact, the coal strike is probably doing the steel-producing industry more good than harm. Buyers are very anxious to receive deliveries of all material already bought and there is more anxiety to buy on the part of some consumers hitherto doubtful. Prices asked are being paid without demur, and concessions from regular market prices have practically disappeared.

There are rumors, as would naturally be expected, of premiums being paid for prompt deliveries, but there is no reason to suppose that premium prices are being paid on any tonnage worth considering. Rolling schedules are now so well filled that consumers and distributors need more stock than formerly, but this does not mean that their deliveries will not be heavy, in general, or equal to actual requirements.

Prices

Market prices are quotable as follows: Bars, shapes and plates, 1.50c.; hoops, bands and hot rolled strips, 2c.; blue annealed sheets, 2.40c.; black sheets, 3.15c.; galvanized sheets, 4.15c.; automobile sheets, 4.50c.; standard steel pipe, 71 per cent basing discount. Independent wire mills are rigidly adhering to $2.50 on nails, while the American Steel & Wire Co. continues its old price of $2.40.

It has become very difficult to buy any semi-finished steel, as the mills prefer to reserve their capacity for their own regular finished steel products. There is no demand for billets, but there is quite a demand for sheet bars, partly because some sheet mills neglected to cover fully on sheet bars when they were selling sheets so freely prior to their recent advance of $3 a ton. Sheet bars were then $29. Now it is certain they cannot be bought at less than $33, and there is a question what price really would bring out tonnage.

Pig Iron and Coke

The pig-iron market in this general territory has almost disappeared. Few merchant furnaces were running when the coal strike started and some of these have had to bank, the result being that there are no regular sellers in the market. Basic pig iron has sold at $24 furnace, against $18 at the beginning of the month. Bessemer and foundry may be quoted nominally at the same figure. There is little inquiry, in point of volume, but there may be two or three insistent buyers of basic iron.

The Connellsville coke market is very narrow in point of tonnage. The merchant furnaces, in view of their low-priced sales of iron, would not buy at over $3.50. Offerings are very limited, and in one or two cases steel interests have been buying, making a market at the moment of $6, against not over $3.50 at the end of March and $2.75@$3 in January. Foundry coke is $6.50, with offerings and inquiry light.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.		$0 38 – $0 40
Acetone	lb.	$0 08 – $0 09	09¼ – 10
Acid, acetic, 28 per cent	100 lbs.	2 35 – 2 50	2 55 – 3 00
Acetic, 56 per cent	100 lbs.	5 00 – 5 25	5 30 – 5 50
Acetic, glacial, 99½ per cent, carboys,	100 lbs.	9 00 – 9 50	9 75 – 10 00
Boric, crystals	lb.	11 – 11½	11½ – 12
Boric, powder	lb.	11 – 11½	11½ – 12½
Citric	lb.		45½ – 46
Hydrochloric	100 lb.	1 10 – 1 20	1 25 – 1 70
Hydrofluoric, 52 per cent	lb.	11 – 11½	11½ – 12
Lactic, 44 per cent tech	lb.	09½ – 10	10½ – 12
Lactic, 22 per cent tech	lb	04 – 04½	04½ – 05
Molybdic, c.p.	lb.	3 00 – 3 25	3 30 – 3 75
Muriatic, 20 deg. (see hydrochloric)			
Nitric, 40 deg.	lb.	06 – 06¼	06½ – 07
Nitric, 42 deg.	lb.	06½ – 06¾	07 – 07½
Oxalic, crystals	lb.	11½ – 12	12½ – 13
Phosphoric, 50 per cent solution	lb.	08 – 08	08½ – 09½
Picric	lb.	22 – 24	24½ – 30
Pyrogallic, resublimed	lb.		1 65 – 1 75
Sulphuric, 60 deg., tank cars	ton	11 00 – 12 00	
Sulphuric, 60 deg., drums	ton	12 00 – 14 00	
Sulphuric, 66 deg., tank cars	ton	17 00 – 17 50	
Sulphuric, 66 deg., drums	ton	20 00 – 20 50	21 00 – 22 00
Sulphuric, 66 deg., carboys	ton		
Sulphuric, fuming, 20 per cent (oleum) tank cars	ton	19 50 – 20 00	
Sulphuric, fuming, 20 per cent (oleum) drums	ton	22 00 – 22 50	23 00 – 24 00
Sulphuric, fuming, 20 per cent (oleum) carboys	ton	31 00 – 32 00	33 00 – 34 00
Tannic, U. S. P.	lb.		60 – 75
Tannic (tech.)	lb.	40 – 45	46 – 50
Tartaric, imported crystals	lb.		26 – 28
Tartaric acid, imported, powdered	lb.		27½ – 30
Tartaric acid, domestic	lb.		– 30
Tungstic, per lb. of WO	lb.		1 00 – 1 10
Alcohol, ethyl	gal.		4 75 – 4 95
Alcohol, methyl (see methanol)			
Alcohol, denatured, 188 proof No. 1	gal.		32 – 34
Alcohol, denatured, 188 proof No. 5	gal.		32 – 34
Alum, ammonia, lump	lb.	03½ – 03¾	04 – 04¼
Alum, potash, lump	lb.	03¾ – 04	04¼ – 05
Alum, chrome lump	lb.	07½ – 08	08½ – 08¾
Aluminum sulphate, commercial	100 lb.	1 50 – 1 65	1 70 – 2 25
Aluminum sulphate, iron free	lb.	02½ – 02¾	03 – 03¼
Aqua ammonia, 26 deg., drums (750 lb.)	lb.	07½ – 07¾	08 – 08¾
